

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

THE
LONDON MEDICAL AND SURGICAL
JOURNAL;

EXHIBITING

A VIEW OF THE IMPROVEMENTS AND DISCOVERIES IN THE
VARIOUS BRANCHES OF MEDICAL SCIENCE.

EDITED BY

MICHAEL RYAN, M. D.

PHYSICIAN TO THE METROPOLITAN FREE HOSPITAL, ETC. ETC.

AND

AN ASSOCIATION OF PHYSICIANS AND SURGEONS.

Quærerere verum. HORACE.

VOL. I.—1837.

LONDON.
PUBLISHED BY THE EDITOR, 4, CHARLOTTE STREET,
BLOOMSBURY SQUARE; AND SOLD BY ALL BOOKSELLERS.

1837.

LONDON; JENKINSON, Printer, Charlotte Street Bloomsbury.

INDEX

TO

VOL. I (1837).

A.

ABDOMINAL tumours, removal of, 839
Abortion criminal, fictitious case of, 59
 Abortion, criminal, history of, 881
Abscess psoas, case of, 886
Absorption, physiology of, 686
Absorption, 686
Acephalous fœtus, 29
Acids, antidotes for, 635
Addison on diseases of the liver, 501
Adipocere accelerated by arsenic, 27
Address of the British Medical Association, 928
Address to Dr. Ryan, 335
Adhesions caused by pericarditis, 329
Adultery, advocates of, 108
Adultery, evils of, 41
Aeriform fluids, deposition of, 658
Affusion cold, in ileus, 857
Air inspired and expired, 561
Alkalies, poisoning by, 635
Almanack, Medical, 427
Amputation, bungling of, 839
Amusements, effects of, on health, 592
Anatomy bill, Irish, working of, 714
Andersonian University, petition of, 185
Anglicus on Medical Education, 330
Aneurism of the heart, 438
Aneurism popliteal, 578
Animal magnetism, 898
Animal heat, theories of, 590
Animal life, definition of, 462
Animals, respiration of, 595
Aorta, aneurism of, 418
Apjohn on gases, 56
Arsenuretted hydrogen, 27
Arsenic, antidote for, 636
Arsenical poisons, 27
Arteries, auscultation of, 45
Arteries, whistling of, 46
Arteries, terminations of, 655
Arteries, physiology of, 621
Arteries, tying of, 485
Arteries, tortuosity of, 655
Arteries, anastomosis of, 655
Artery, ulnar, wound of, 579
Asphyxia, real cause of, 719
Attraction capillary, 645
Auriculo-ventricular diseases, 343
Auscultation, account of, 6; mediate and immediate, 6
Auscultation, obstetric, 46

B.

BALBURN on uterine diseases, 54
Baldness, cure of, 128
Baltimore Hospitals, reports of, 548
Barry and **Corrie's** reports, 189
Baryta, poisoning by, 636
Basis of conjugal happiness, 43
Belfast Fever Hospital, 318
Bell's, Sir C., discoveries, 558
Biographical Sketches, 378
Bladder, rupture of, 862
Blood in the lungs, in a day, 590
Blood, quantity of in different organs, 658
Botanical Society Report, 744
Blundell on diseases of women, 118
Body, renewal of, 687
Bouillaud on rheumatism, 90
Brain, diseases of, 28
Brain, concussion of, 365
Breast, cancer of, 314
Bright on jaundice, 740
British Medical Association, 651
British Medical Association, defence of, 837
Brodie's, Sir B., Oration, 800
Brodie, Sir B. and the Hunterian Manuscripts, 865
Bronchial respiration, 7
Bronchitis, account of, 368
Bronchitis, pathology of, 175
Bruits or sounds of the heart, 10
Bruits cardiac, 16
Bruit de diable, 46
Bruit encephalic, 45
Bullock's case of pebble in the larynx, 159
Bureau on physical education, 464
Bureau on cancer, 308
Bureau on homœopathy, 540
Burns, remarks on, 539

C.

CALCULUS in the ureter, 307
Caloric, evolution of, 591
Cancer, cure of, 308
Cancer of the heart, 437
Capillaries, anatomy of, 632
Capillaries, muscularity of, 656
Carbon secreted in a day, 590
Cardiac orifices, diseases of, 341
Cardiac diseases, 436

Carditis acute and chronic, 435
 Carditis, history of, 435
 Carmichael on tubercles, 29
 Carotid artery, ligature on, 485
 Carlow Hospital, 319
 Carowatti, Hancock on, 713
 Castle's Botany, 810
 Castle's Medico-botanical notes, 856
 Castle's British Flora Medica, 89
 Catarrh pathology of, 175
 Cavan Fever Hospital, 318
 Cerebro-spinal system, 464
 Chamamilla, use of, in dentition, 484
 Charing Cross Hospital abuses, 61
 Charter of the London University, 156
 Chemical union in the decomposed human body, 27
 Chorea, case of, 613
 Chronic disease of the kidney, 300
 Chronic hydrocele, 857
 Clarke on Eastern Medicine, 387
 Clarke on the Nervous System, 126
 Clinical Medicine, 46
 Colic, use of rectal tube in, 105

VOL. I.—(1837.)

NOTES OF LECTURES ON PHYSIOLOGY.

By DR. FLETCHER.

*Delivered in the Argyle Square School of
Medicine, Edinburgh.*

No. XVII.

SENSATION.

Animal Magnetism—Dr. Bertrand on Somnambulism—Peculiar Taste of Magnetized Water—Sacred Well of St. Medard—Convulsions produced by drinking its Water—Effects of Imagination, and a Magnetized Handkerchief—Magnetized Rings—Magnetized Trees, Paper, and Boxes—M. de Puysegur on the Influence of the Will—His Treatment of Patients—Singular Effects of a Visit to his House—Delenze on Magnetic Emanation—Georget on the necessity of Determined Attention in Magnetizing Patients—Contrary Opinion of Dr. Bertrand—Case in Point—Sound Sleep produced by Magnetism.—Origin of Animal Magnetism, Supported by Wirdig, Paracelsus, and Van Helmont—Magnetic Treatment of Wounds—Cure by Sympathy—Ointment made with a Human Skull—Magical Mode of producing Perspiration—Talismans and Enchantments—The Salt of Blood—The Lamp of Life—The Sympathetic Alphabet—Thouret on the Taliacotton Operation—Sympathy between a Nose at Brussels, and an Arm at Boulogna—Mesmer and Deslon—Life and Death of Taliacotton—Statue to his Memory, with a Nose in his Hand—Verses by Voltaire and Hudibras—French Commission of Inquiry—Bertholet and Lavoisier—Nature and Extent of the Magnetic Fluid—Influence of the Celestial Bodies—Distribution, Propagation, and Augmentation of Magnetism—Flux and Reflux—Effects on the Animal Body—Influence on the Nerves—Analogy with the Loadstone—

No. 1.

Opposite Poles—Accumulation, Concentration, and Transference of the Magnetic Fluid—Reflected by Glass—Bodies which Neutralize it—Its Application to Medicine—Mediate and Immediate Mode of curing Diseases—Magnetic Elixir of Immortality—Deslon, on the Existence, Nature, and Utility of Animal Magnetism—Apparatus—Magnetic Trough—Magnetic Chains—Magnetic Rod—Magnetized Piano Forte—Experiments with an Electrometer and a Needle—Magnetic Songs—Treatment of Patients—Singular Effects produced—Convulsions.

“The somnambulists,” says Dr. Bertrand, “pretend that they detect in magnetized water a peculiar taste, which reveals to them the presence of the magnetic fluid. The counterpart of this marvellous circumstance is to be found among the convulsed votaries of St. Medard, with respect to the water of a well near the tomb of the celebrated Deacon Paris; and the heads of that sect cite a thousand observations to prove that the convulsionists recognise that water, not only by its taste, but by other remarkable effects, which they experience. I shall mention only one of these, which was that of a convulsionist, whom his brother could not deceive with holy water, substituted, unawares, for the water of the sacred well. With respect, however, to the direct experiments made with the view of ascertaining whether the somnambulists really discovered a peculiar taste in magnetised water, independently of all prepossessions, there is not one of all those which I have seen tried, with proper precautions, that has afforded positive results; and the proofs which magnetizers bring forward, are far from being more conclusive than those which the convulsionists furnish in favour of their well-water.

“The magnetizers adduce a thousand

facts to prove that magnetized objects have produced, on somnambulists, effects altogether independent of imagination; because these objects have been presented to them, without their being aware of their being impregnated with the magnetic fluid. What at first sight could be imagined more conclusive than the fact, that a young person was thrown into a state of somnambulism by means of a handkerchief magnetized at a distance of three hundred miles from the place where he dwelt? Nevertheless, this case proves nothing; for a handkerchief which was *not* magnetized, placed upon a patient in the same circumstances, produced the same effect.

"A magnetizer, obliged to remove from a distance from a person whom he is accustomed to somnambulize, and who pretends that he cannot sleep during his absence, takes a ring from his finger, and says,—'Take this ring; preserve it carefully; and put it on your finger at the hour when I have been accustomed to magnetize you. It will make you sleep half an hour every day.' The magnetizer departs; is absent for a fortnight; and, during all that time, the ring produces the effect that was foretold. This they explain by saying, that the ring had become saturated with fluid from the body of the magnetizer. About ten years ago, however, some magnetizers were obliged to admit the absurdity of the ideas generally entertained; and to allow that the imagination has a great share in bringing about the effects produced. It was only necessary for them to say to their patients, 'You will go and sit under such a tree; and you will fall asleep there for so long a time.' The patients did so; and the tree, although *not* impregnated with magnetic fluid, produced the same effect. Again, they said to them, 'You will fall into a state of somnambulism on tearing this paper,' or 'on opening this box; and that which they predicted, did not fail to come to pass.

"A belief in the power of the will of the magnetizer, was introduced by M. de Puysegur, 1784. He considered it to be the foundation of animal magnetism; and did not think it necessary to have recourse to any magnetic fluid. In his treatment of patients at Busancy, by the exercise of his will alone, he gave them power to sleep, on lying under a tree, or to wake by embracing it. But there is another fact which proves still more strongly to what point he carried his

belief in the power of his will. Among the peasants who flocked to his house, often from a great distance, there were some who (their imaginations excited by all the wonders that were told of his treatment) did not need even to submit themselves to it in order to experience its effects, but fell into a state of somnambulism the instant they set out on the road to Busancy. This was attributed by M. de Puysegur to the determined will he had to cure all who resorted to him.

"I believe in an emanation from myself," says M. Delenze, "because the magnetic effects are produced without my actually touching the patient. I do not know the *nature* of this emanation, I know not whether it be *material* or *spiritual*; nor do I know to what distance it extends. But I know that it is sent forth and directed by my will; for when I cease to *will*, it ceases to *act*." M. Georget is of the same opinion. "It is necessary that the two persons engaged in the operation, should direct their attention strongly and exclusively to the production of the phenomenon in question. Both the *magnetizer* and the *magnetized* should have the *intention* to produce somnambulism. Often when my thoughts were distracted by other matters, I could not produce any phenomenon; and when I thought the operation was completed, the patient opened his eyes, and told me he felt nothing."

Multiplied experiments have convinced Dr. Bertrand of the fallacy of all these notions. "A young person (about twenty years of age) had been subject, for four or five years, to very severe headaches, which, though not very frequent at first, soon recurred every week; and, during the last few months, several times a week, and with so much severity as to confine her to bed. At first I employed the means indicated by ordinary medicine, particularly foot-baths, bleeding, and leeches; but the relief they produced was hardly appreciable.* At last I resorted to magnetism.

* So far as we can judge from the scanty particulars of this case, furnished by Dr. Bertrand, the treatment does not appear to be adapted to the occasion. It is not every case of headache (especially in a young female) that is benefitted by foot-baths, bleeding, and leeches. The subsequent history confirms this view. A case which required *depletion*, would not have been benefitted by *animal magnetism*.

First sitting.—The patient fell soundly asleep in seven or eight minutes; continued so for half an hour, and could not be awakened except by a loud voice. *Second sitting.*—Sleep came on some minutes sooner, and appeared to be still more profound. It ceased spontaneously about the same time as in the former instance. *Third sitting.*—Sleep came on in three minutes. There was no appearance of somnambulism. The pain in the head did not come on during the day, which surprised the patient, who was not accustomed to pass so long a space of time without an attack. Every time that the patient awoke from her profound slumbers, she complained of a violent pain in the head; but I removed it in a few minutes, by gestures. I continued the treatment for three weeks, at which time the sleep, which had all along been diminishing in length and intensity, ceased altogether. This insensibility to the action of magnetism, is considered by magnetizers as the indication of a perfect cure. I then discontinued the treatment; and, during six entire months, the patient was free from headache; but it has since returned, though less frequently and severely. In this case sleep was produced without an exertion of my will to that effect; and what necessity, therefore, is there to recur to that hypothesis?

Animal magnetism, it seems, took its rise in the sixteenth century. Many distinguished men became its partisans; among whom may be mentioned Paracelsus and Van Helmont. Wirdig thus quaintly and strongly expresses himself. "All nature is magnetic. The whole world is supported by magnetism. All sublunary vicissitudes are caused by magnetism. Life is preserved by magnetism. The destruction of all things takes place by magnetism." Van Helmont wrote a work on the *Magnetic Treatment of Wounds*. The cure of wounds by persons at a distance, or by sympathy, as it was called, was also much in vogue. "It was sufficient to have the sword which had inflicted the wound, or a handkerchief dipped in the blood, to cure the patient at a distance; which was effected by the application, to the sword or the handkerchief, of an ointment proper to act through the medium of the magnetic fluid. They gave to this ointment the name of *Unguentum Armarium*. Its great virtue depended on the powder of a human skull, which they mixed up with some fatty body, in order to anoint

the weapon which had inflicted the wound; and that sufficed to effect a cure; provided it was applied in proper time, that proper care was taken, and that the wound was preserved from contact with the air.*

"This is not the only instance in which virtues have been ascribed to an insignificant remedy, which were really due to accessory circumstances. It was thus that, even in the eighteenth century, an admirable remedy was contrived for producing diaphoresis. It was sufficient to make a composition, into which entered the urine of the patient. In order, however, that the remedy might succeed, a precaution was to be taken, (*purely accessory, but nevertheless indispensable*). It consisted in placing the patient, well covered up, in a warm bed, and to administer, during the magic operation, several glasses of warm drink!

"The magnetic influence was not confined to the cure of wounds. It was employed in the formation of talismans and enchantments; and in the belief of its efficacy was founded the art of injuring by the excrements. The principal means of communicating at a distance were: 1. *The Salt of Blood*; a composition, into which entered the blood of the person at a distance, of whom it was wished to have intelligence. While the person remained well, this composition retained its bright red colour; but became dull on the occurrence of disease or death. 2. *The Lamp of Life*; which burned with a clear and brilliant flame, so long as the person who had furnished it was well; but which went out

* Fully to enter into the spirit of these manoeuvres we should recollect, that the method of treating wounds at that time in vogue, was by applying oils and balsams to them, which retarded the cure instead of promoting it. It was discovered, however, that the best way of treating a simple wound, was to bring the divided parts into a position, and to maintain them so, without the application of any extraneous substance whatever. This was accordingly put in practice; and the application of ointment to the weapon, was merely for the sake of falling in with the superstitious notions then prevalent. The "powder of a human skull," was admirably adapted to assist in what was considered to be a magical process. Though no longer among our remedies, so late as the time of William and Mary, great importance was attached to it. The king himself, in his last illness, had to swallow the revolting dose.

at his death. 3. The *Sympathetic Alphabet*, for the purpose of communicating at great distances, and of conversing with friends, however far removed. It was formed by removing from one of the arms of each of the two persons who wished to correspond, a small flap of skin, of equal form; applying the flap taken from one to the arm of the other reciprocally. Upon these pieces of skin, which soon became part of the new individual, were traced the letters of the alphabet; and when one of the persons touched different letters with a stylet, the other person felt a pricking sensation in the corresponding letters."

"This theory was confirmed," says M. Thouret, "by an extraordinary fact which took place about that time. An inhabitant of Brussels, having had an artificial nose made for him, by the Taliacotian* method, returned to his ordinary dwelling place, where he continued to live in good health, the operation having succeeded. All at once, however, the new part became cold, pale, and livid; in short, it putrified, and fell off. There was no apparent cause for this unexpected catastrophe; but it was soon discovered that on the very same day in which the supposititious nose fell off at Brussels, a porter at Boulogne who (for a suitable reward) had furnished the necessary portion of skin from his arm, died in that place. A little time afterwards, a similar fact (no doubt equally fabulous) was brought forward. They had great weight with those who were disposed to receive with eagerness everything which seemed calculated to minister to the taste which man naturally has for the marvellous."

During the latter half of the last century, the celebrated Mesmer zealously taught the system of animal magnetism in Paris. He received a severe check, however, by the death of M. Court de Gébeline, author of the "Primitive World," whom he was treating. His death was announced by a journal in the following manner, which made a great sensation: "M. Court de Gébeline has just expired, *cured by animal magnetism.*" The distinguished

Bertholet likewise published an opinion, that "the doctrine of animal magnetism, and the practice founded upon it, were perfectly chimerical." Indeed the system was scouted by the profession in general; but M. Deslon, a well-known physician, became its advocate.

In 1784 a commission of learned men and physicians (among whom was La Voisier) was appointed to examine into the validity of its claims. "Animal magnetism," said its advocates, "is a fluid universally distributed, and is the medium of mutual influence between the celestial bodies, the earth, and animated beings. It is so distributed as to allow of no void; it is subtle beyond comparison; it is susceptible of flux and reflux, and is capable of receiving, propagating, and communicating all impressions of motion. The animal body experiences the effects of this agent; and it is by insinuating itself into the substance of the nerves, that it effects them immediately. It exhibits (especially in the human body) properties analogous to those of the loadstone, different and opposite poles being discoverable. The action and virtue of animal magnetism, may be communicated from one body to other bodies, animate and inanimate. The action may take place at a long distance, without the aid of any intermediate body; it is reflected by glass, and communicated, propagated, and augmented by sound. The virtue may be accumulated, concentrated, and transferred. Although this fluid is universal, all animated bodies are not equally susceptible of it. There are even some (although very few) which have properties so opposite, that their presence alone destroys all the effects of the fluid in other bodies. Animal magnetism can cure diseases of the nerves *immediately*, and *mediately* those of other parts. It improves the action of medicine, and promotes and directs salutary crises, in such a way as to bring them under our control. By its means the physician is made acquainted with the state of health of every individual, and can judge with certainty of the origin, the nature, and the progress, of the most complicated maladies. It prevents their increase, and effects their cure, without ever exposing the patient to dangerous effects, or unpleasant consequences, whatever may be the age, the temperament, or the sex. Nature offers to us, in magnetism, a universal means of cure and preservation for mankind."

Such was the agent which the com-

* The celebrated surgeon, Taliacotus, was Professor of Theoretical and Practical Medicine, in the University of Boulogne. He was born in 1546, and died in 1600. The magistrates honoured his memory with a statue, in the hand of which they placed a nose. He was made the subject of humorous verses by Hudibras and Voltaire.

missioners had to examine ; and M. Deslon, its advocate, engaged to prove to them its existence ; to communicate his knowledge of its nature, and to demonstrate its utility in the cure of diseases. The following is an account of the manner in which the latter was attempted :—“ The commissioners saw, in the middle of a large room, a circular oaken chest, about eighteen inches high, which was called the *trough*. The cover was pierced with holes, through which issued bent iron branches. The patients were placed round the trough, in rows, and each held an iron branch, which, by means of its bent shape, could be applied directly to the part affected. A cord passed round the patients, united them altogether. Sometimes they formed a second chain, by joining hands, so that the impression received by the left, was communicated by the right, and thus circulated through the whole. A piano forte was placed in a corner of the room, and different airs, in various movements, were played on it. The voice was sometimes added. Those who magnetized patients, had in their hand an iron rod, about ten or twelve inches long.”

M. Deslon gave them the following explanations:—“ 1. This rod is a conductor of magnetism, which it concentrates on its point, and of which it renders the emanations more powerful. 2. Sound is also a conductor of magnetism ; and in order to communicate the fluid to the piano-forte, all that is necessary is to approach to it the iron rod, and the magnetism is transmitted by the sound to the patients. 3. The cord which surrounds the patients is designed (as well as the chain of hands) to augment the effects of the fluid by communication. 4. The interior of the trough is so constructed, as to concentrate the magnetic fluid. It constitutes, in fact, a grand reservoir, whence the fluid is conducted away by the iron branches which are plunged into it.” By means of an electrometer and a needle, the commissioners satisfied themselves that the trough contained nothing either electric or magnetic, nor could they discover in it any physical agent capable of producing the effects attributed to animal magnetism.

Besides the iron branches, the cord, and the union of hands, the patients were magnetized *directly* by means of the finger, or the iron rod moved about before the face, or above or behind the head, or over the affected parts. They

were likewise acted on by being looked at steadily, but more particularly by the application of the hands, and by the pressure of the fingers on the *hypochondrial* and *hypogastric* regions, an application which was often continued for a long time sometimes even for several hours ! The magnetized piano-forte was supposed to communicate its virtue to the person who played on it ; and when the latter sang, the magnetic influence floated on the sounds of his voice to the ears of his patients.

As to the effect of all this on the patients, “Some were calm, and felt nothing ; others coughed, spat, felt a slight pain, a local or general sense of heat, and had perspirations ; others were agitated, and tormented by convulsions, which were remarkable for number, duration, and severity. Whenever one patient fell into them, several others were attacked. They were attended by the expectation of a turbid, viscous fluid, sometimes streaked with blood ; of which one young man brought up a considerable quantity. These convulsions (of which the commissioners saw one that lasted three hours), were characterized by involuntary and precipitous movements of all the limbs, and of the whole body, by wandering of the eyes, by piercing cries, weeping, hiccough, and immoderate laughter. They were preceded or followed by a state of languor, depression, and reverie. The slightest unexpected noise gave rise to startlings ; and it was remarked that a change in the tone or measure of the airs played on the piano-forte, influenced the patients, so that a brisker movement agitated them more, and renewed the violence of their convulsions. The latter were inappropriately called *crises*, because they were considered as analogous to those salutary changes which nature sometimes produces in the course of diseases. More females than males were always affected with these convulsions, which it took an hour or two to produce, but which, when once established, spread with great rapidity.

All the patients appeared completely under the control of the magnetizer ; so that even when apparently in a lethargy, a word, a look, or a sign from him, could rouse them from it. The magnetic fluid was not cognizable by any of the senses, notwithstanding what had been said of its colour, taste, and smell ; and the commissioners threw overboard at once the doctrine of celestial influence.

AN ESSAY
ON THE ORIGIN AND NATURE OF
TUBERCULOUS
AND
CANCEROUS DISEASES.

(Continued from p. 956, No. 270.)

READ TO THE MEDICAL SECTION OF THE
BRITISH ASSOCIATION, ON THE 23RD
OF AUGUST, 1836, BY RICHARD CAR-
MICHAEL, M. R. I. A., CORRESPONDING
MEMBER OF THE ROYAL ACADEMY OF
MEDICINE OF FRANCE, ETC. ETC., AND
CONSULTING SURGEON OF THE RICH-
MOND SURGICAL HOSPITAL, ETC. ETC.

"I shall not notice the different species of intestinal worms, but shall call the attention of my hearers to the variety of worms with which the solid tissues of all animals are infested. These have engaged the attention of modern pathologists and naturalists in no slight degree; but we are indebted chiefly to the labours of Brera, Rudolphi, Bremser, Laennec, and Cruveilhier for most interesting information on this subject.

"The most simple form of animal matter, as yet acknowledged to be in possession of independent existence, is the hydatid. It is a vesicle filled with a fluid as clear, but of more consistence than water. This vesicle is inclosed in a capsule or cyst, which varies from the consistence of a serous membrane to the firmness of cartilage or even of bone. Bremser justly considers this cyst as the product of the tissue in which the parasite is embedded.

"There are only two kinds of hydatids discovered in man: the one most frequently found is termed by Laennec, *acephalocystis*, because it is simply a vesicle not furnished with either head, mouth, or suckers. By Rudolphi, Bremser, and others it is called *echinococcus*. The other furnished with a head, neck, and suckers, by which last it is thought to imbibe its proper nourishment, is a step above the first in the scale of animal life, and is called from its form *cysto-circus*. It chiefly infests the lower animals of the mammalia class, being comparatively but seldom found in man. However, instances of its presence in human beings are detailed by Werner, Ficher, Treutler, Brera, and Rudolphi.*

It was discovered and described by Pallas and Goeze. But the *acephalocystis* is that form of hydatid which is to be met with most generally in man. In the *Leçons Orales* of M. Dupuytren, we find a most interesting article on hydatid tumours developed in the muscles and in the viscera. These were chiefly *acephalocystis*, but he mentions some instances also of the *cysto-circus* species.

"The hydatid multiplies its kind by the production of diminutive hydatids within its cavity. By the growth of these the parent hydatid is pressed against the cyst. The cyst increases in size from distention, so that if an hydatid tumour be punctured, a multitude of these vesicles will escape. The hydatid, like any other living creature, will of course die a natural death. Those who have watched the progress of dissolution, observe that the first appearance of decline is, that the fluid it contains, from being limpid becomes turbid and opaque, and gradually thickens to the consistence and appearance of softened cheese. The hydatid itself or vesicle becomes wrinkled and contracted, and finally it becomes transformed into a calcareous mass. This final termination of the hydatid is mentioned by John Hunter, Rudolphi, Bremser, Cruveilhier, and all who have treated on the subject. By some the appearance is compared to moistened chalk or putty. The celebrated Ruych* was well acquainted with those transmutations of the hydatid, and makes the shrewd conjecture that those melicerous and atheromatous tumours such as we meet every day on the scalp, are nothing more than transformed hydatids; and Cruveilhier was of a similar opinion, viz. that encysted tumours, whether containing serum or melicerous matter, are of hydatid growth and origin.

"*Acephalocystis* hydatids are often connected together like bunches of grapes, the stalk of which is attached to part of the human body, and yet in this state they are admitted to be a collection of animals, each possessing an independent state of existence. These bunches of hydatids attached to something analogous to a placenta, are often found to be the component parts of false conceptions. They are termed by Wiessmantel, *hydrometra hydatica*. Bremser† has no doubt that they are distinct animals, though

* *Opera Omnia*, vol. i. p. 225, *Anat. Med. et Chir.*

† Bremser, p. 313.

* Bremser, 286.

tied together and fixed to the substance of the body; for he justly observes that a great number of aquatic animals are thus attached, of the individual animality of which no person entertains a doubt. Are we to conclude that hydatids (which, though known from the earliest periods, have been only acknowledged in modern times to be distinct animals) form the last link in the chain of animal life, and that there are not still simpler forms also in possession of a separate existence?

"Tubercles, I have stated already, have no connexion by means of vessels with the surrounding tissues in which they are imbedded, as is apparent from the preparations before you; they are commonly found in small regular circumscribed masses. They at first, generally before they undergo any transmutation, have the appearance of semi-transparent vesicles; even those that are opaque, on a close examination, I have often found to be hollow; in fact they are thickened vesicles or cysts. But even should they not present the vesicular form, but appear as solid masses without connexion of vessels with the surrounding parts, I do not see why their solidity should be an objection to their possession of an independent vitality. They may continue in this state for months, nay years, without their presence being suspected. As long as they themselves retain life, they do not occasion any stimulus or disturbance in the parts in which they have their nidus, to throw them off; but when they die, they act like extraneous bodies (as we know from the facts respecting the guinea-worm) and occasion local inflammation and general disturbance of the system. They soften afterwards, and if simulated in the lungs may be expectorated, and the expectorated matter, as was proved long ago by Stark, is neither pus nor mucus, but is the dead substance of the dead and softened tubercle.

"The present prevailing doctrine concerning tubercles, viz. that they are lifeless masses of unhealthy or vitiated coagulable lymph, incapable of becoming organized, is contrary to the laws which govern animal bodies. No lifeless mass can remain in the tissue of a living body without exciting inflammation and suppuration, by which it may be expelled. Besides, the hypothesis is over strained. Who ever saw coagulable lymph deposited in the form of semi-transparent grey vesicles, or even in these regular compact masses like grains of shot? which we see in the preparations before us, and into

which no vessels appear, although all the surrounding tissues are red with injection; and who ever witnessed depositions of lymph first softening and then changing into calcareous masses? But in this, the last transmutation of tubercle, we must be struck with the close resemblance which it bears to the acknowledged animal, lydatid.

"Before I proceed farther in my argument, I should wish to call your attention to the following facts, concerning the *filea medinensis* or guinea worm, of which I have spoken. We know that this worm, which Rudolphi considers peculiar to the body of man, may remain for months, nay, whole years, without producing any sensible uneasiness or accident; that it is only when it approaches the skin, when it pierces it, that pain and other troublesome symptoms are produced. The treatment consists, when the worm thus exposes itself, in seizing the part exposed and rolling it with much caution round a small stick, which is turned very gently every day for fear of breaking the body of the animal; for should this take place the remaining part of the animal would die, and giving, only when dead, the stimulus of an extraneous body, causes inflammation along its entire extent, which is sometimes considerable, the worm having been seen varying in length from one to three feet.

"I mention this fact, as throwing much light upon the effects of parasites on man, and other animals. As long as the parasite retains the principle of life, it causes comparatively little uneasiness; but as soon as it becomes dead matter, it occasions inflammation in the surrounding parts, the first step to that process by which it is removed from the system. If we apply this fact to tuberculous diseases, it will explain many of their symptoms in a satisfactory manner.

"But to return to our argument: let us look to tubercular formations in other parts; they are not caused by inflammation, and how will the doctrine of the deposition of vitiated coagulable lymph account for the presence of those enormous accumulations of regular compact masses of various consistence which are found in the abdomen, to which Doctor Baron has given the name of tuberculated accretions? Medical Journals and Transactions afford an ample supply of these instances. I shall glance at one or two. Doctor Simunins* relates a case which

* Medical Communications, vol. 1.

during life was thought to be dropsy, and therefore a fruitless attempt was made by tapping to draw off the water; but after death it was found that the enormous distention of the abdomen was owing to a collection of hydatid tumours of various sizes and consistence.

"I have myself given to the public a similar case, which was attended by my friend Doctor Jackson of Dublin, and the late Doctor Joseph Clarke. The swelling of the abdomen was supposed to be pregnancy until the time of parturition had passed. On examination after death we found globular masses, varying from the size of a pea to that of a large orange, each filled with gelatinous fluid or substance which compressed all the viscera. When these masses were removed, the enormous growth may be estimated, when I assure my hearers that nearly a large washing tub was filled by them. How life could be preserved during the accumulation of such a mass, which seemed only to occasion death by its pressure on the surrounding viscera, surprised us not a little.

"Doctor Pulteney relates a case of an extraordinary enlargement of the abdomen owing to a fleshy encysted tumour.* 'It was one of those tuberculated accretions so well known, and weighed, when removed, fifty-six pounds. It was made up,' Doctor Pulteney observes, 'of a congeries of smaller tumours from the size of a nutmeg to that of an egg, and many were much larger. These were closely compacted and intimately united to each other, each, however, being a separate cell or cyst, with an extremely thick, fleshy coat, containing in its cavity a small quantity of fluid,' &c. &c. But enough of this case is detailed to show its nature; that it was a collection of hydatids which had gone through many of their transmutations from the vesicular towards the solid form.†

"I shall not take up your time by the detail of cases familiar to every practitioner of experience, and with which all the medical periodicals are amply furnished. Enough has been stated, to evince how insufficient is the doctrine of depositions of unhealthy lymph to ac-

count for a class of diseases which are not preceded by inflammation, the general precursor of the deposition of lymph, and if they are at all attended with inflammation, it is either the consequence of the death and softening of those masses, or of their increase to such a degree as to press upon and injure the viscera in their neighbourhood. On the contrary, the doctrine I venture to advocate, that of their possession of independent vitality, and of their faculty of increasing from their inherent powers, satisfactorily accounts for all the symptoms and phenomena which they occasion.

"Do acknowledged entozoa arise from the seed or eggs of parent animals of the same description, or are they the product of what is called equivocal or spontaneous generation? I am decidedly of the latter opinion respecting the lowest grade both of animals and vegetables, in which no sexual organs have been discovered. Twenty-five years ago, with the view of explaining the origin of cancer, I advocated this doctrine in my work upon that disease; and since, I find, that it has every day become more and more generally adopted, and among others, by those distinguished naturalists, Bremer, Blainville, and Cruveilhier, who have given the energies of their powerful minds to ascertain the origin, growth, and decline of the entozoa. It is well known to all naturalists, that whenever a slow decomposition of animal or vegetable matter is going forward, assisted by heat and moisture, immediately new forms of organized beings arise; thus the mucus or mouldiness which grows in all damp places, fungi, mushrooms, and lichens take place under similar circumstances. It may be said that the seeds of those vegetable productions are floating in the air; but how account, on the necessity of seminal or oviparous generation, for the green vegetable matter of Priestly? How account for those numerous species of entozoa which are found in the most hidden tissues or organs of the body? How account for the presence of worms in the intestines of an unborn foetus? But I shall not draw any farther argument from intestinal worms, because many will argue that their eggs are admitted with the food, although it is more rational to suppose that they come from within, and not from without the body, no such worms being ever seen elsewhere, and they can only live for a very short time out of their proper nidus, the intestines. Besides, not only every animal,

* Mem. Medical Society, vol. ii. p. 265.

† A large collection of hydatids, taken from the abdomen of a foetus belonging to the Museum of the Infirmary of Bristol, was shown to the section to illustrate this subject.

but each division of its intestinal canal, has its own peculiar species of worm. Thus the *lumbicus teres* does not reside in the rectum, nor the *ascaris* in the small intestines.

" 'Some light,' Cruveilhier says,* 'may be thrown on the obscure subject of spontaneous generation, from the fact of the production of the infusoria in every liquid in which we macerate a vegetable or animal substance. It at first becomes charged with organic globules, which move in every direction by their own innate powers, totally independent of the force of gravitation. These globules are more or less active, and resemble a good deal the globules of the blood, which move with so great a rapidity; desiccation alone arrests the movement of those globules, and humidity again restores it to them. If the maceration is continued, the animals of infusion succeed those organic particles, which, like the spawn of the frog, enjoy great powers of locomotion as well as those of the will, so as to be able to avoid an obstacle, for in their movements they are not observed to strike against each other; in a word, they appear to be gifted with a high degree of vitality.' From these facts and views we can no longer admit the axiom of Harvey, 'omne vivum ex ovo,' but rather in its place substitute that of O'Kerr, 'omne vivum e vivo.'†

" Although 'omne vivum ex ovo' originated, I believe, with the immortal Harvey, yet his clear sighted mind could not overlook the fact, that new forms of existence are always arising in humid places where decomposition of course was going forward. In the twenty-seventh section of his work, on the generation of animals, in which he argues that the foetus, like the chick in ovo, draws its nourishment by its own innate powers, he illustrates this fact by the following passage: 'What shall we say of those animals produced within our own bodies? No one can doubt but that they grow and are governed by their own independent life (*propria anima*); such as the *lumbici*, *ascarides*, *pediculi*, &c. &c. For an animal can be produced in almost all dry places which have become moist, or in those humid places which have become dry.‡'—In fact,

in the situations best adapted for the process of putrefaction or decomposition, without implying the necessity of the agency of eggs or seeds. In another part of the same section he supports the same argument, and as I have lately found to my great surprise, by the admission of the very facts which I am now endeavouring to establish, viz.: the independent vitality of cancer and other fungous parasites. These are his remarks:—'In the same manner the parasitic plants and fungi of trees exist: but even in our own bodies we have cancers, sarcomatous, melicerous, and other malignant tumours, which grow and are nourished as if by their own innate vegetative life, (*quasi propriâ animâ vegetativa*.) whilst the parts in which they grow become extenuated and wasted, in consequence of their defrauding the body of its nutritious juices.*

If worms of the intestines do not arise from seed or eggs, from what cause do they spring? Bremser, who spent twelve years in close application to the disgusting but useful subject of studying the entozoa, advocates the doctrine of their spontaneous generation by facts which cannot be rebutted; and he is of opinion, that worms arise in those who either take in nourishment of an indigestible quality, or who swallow more food than they have powers to digest. In either case materials are furnished for their production in the way we have just considered.

" Are not hydatids and tuberculous masses formed in the solid tissues of animals, from the precise same causes? Either improper nourishment is taken, incapable of being assimilated, which vitiates the whole mass of fluids, and is unfit to replenish the waste of the system, or else

more is admitted than can be assimilated; for we ought to recollect that the last act of assimilation takes place in the lungs, where the blood is submitted to the influence of the air; and this circumstance may tend, in some degree, to explain the greater frequency of tuberculous diseases in the lungs than in any other part of the body.

"Dr. Clarke, in his treatise on pulmonary consumption, truly observes, 'that what is usually considered the early is in reality an advanced stage of the disease,) tubercular phthisis,) and that tubercle is a secondary affection originating in a peculiar morbid condition of the general system.' What is this morbid condition which Doctor Clarke contends for? Is it not a vitiated state, first, of the fluids, and afterwards of the solids, in consequence of imperfect assimilation?

"It is many years since I first advocated the doctrine that carcinoma ought to be classed amongst the entozoa, and I am every day more attached to that opinion. There is in every carcinomatous structure two distinct substances. One is a hard cartilaginous mass which admits of being injected, the other is of the consistence of brain, or a medullary substance, which does not admit of being injected. The latter I esteem the true entozoa or parasite, the former, *i. e.* the cartilaginous part, I look upon as the barrier which the surrounding tissues throw up to insulate the parasite. This liver of a sheep before you, which contains the animals termed '*faciola hepatica*,' and by the victuallers in Ireland '*flukes*,' will serve to illustrate the subject. Groups of these animals, which, when alive, move with a brisk motion in warm water, are contained, as you see, in cysts of a cartilaginous hardness, or in the biliary ducts themselves. Now the walls of these cysts are capable of receiving injection, as you may perceive by the preparation before you. We must infer, therefore, that those cysts have been formed, not by the parasites, but by the parts in which they are imbedded; and thus a barrier is placed between them and the organs in which they are lodged. When they are produced in a biliary duct there appears to be no necessity for the formation of a cyst; the duct answers the purpose, but the duct becomes enlarged and cartilaginous, as you may see in this preparation. A similar occurrence takes place in the bronchial tubes when tuberculous matter is formed in them. This is finely delineated in Plate 1. Fig. 4 of Doctor Carswell's Illustrations of Tuber-

cle. In the one instance we cannot deny the animality of the contents of the duct; but in the other it is inferred from the various facts and arguments contained in this paper. I do not conceive that any argument is afforded against the opinions I advocate on the grounds that tuberculous matter may take the form of the part in which it grows. The same occurrence is observed when vegetable fungi sprout in narrow and confined places, and consequently will take their form and shape from those external causes, and yet no one doubts but that they grow by their own internal powers. Now, in order to see the medullary portions of a carcinomatous mass, make a section of it in any direction, and you will perceive, on pressure, the medullary ramification to ooze out at each of its divided branches.

"Fungus medullaris or medullary sarcoma, and fungus hæmatodes belong to the same family of disorders, but is chiefly composed of the medullary substance, there being but a very small proportion of the cartilaginous structure. The great distinction between these two last species of the same family is, that in fungus medullaris the medullary mass is contained in a cyst. In the latter there is no distinct cyst, but the medullary mass seems to be subdivided by membranous or semi-cartilaginous bands into separate spheroidal masses; each of these is probably a distinct fungus, the aggregate constituting the diseased structure or parasitic tumour.

"Now, these maladies are much more rapid and destructive than carcinoma, because there is no sufficient barrier thrown up by the neighbouring parts to obstruct their progress. Besides, there is scarcely an instance met with of fungus medullaris or fungus hæmatodes, in which the disorder has been confined to one organ. If we see it in any one part, we may with great certainty infer that it exists in others, and, therefore, conclude that it is owing to some fault in the constitution.

"In vol. viii. of the Medico-Chirurgical Transactions, are several interesting cases detailed by Mr. Langstaff, exemplifying the nature and universality of the attacks of fungus medullaris on almost every organ of the body. In the second edition of my work on Cancer, published in 1809, is an account of the symptoms of this same disease in a gentleman* who had those tumours on almost every part of his body. I regret that there was no post mortem

examination; but have no doubt but that similar tumours would have been found universally disseminated on the internal organs. Now, although the disposition to carcinoma is also often constitutional or general, yet it is not always so; it is sometimes merely local, and I shall explain under what circumstances it is so.

"1st By a local disposition to cancer I mean that change in a part, from a healthy, sound structure, to a morbid one, which has been occasioned in an otherwise healthy person, either by a direct and immediate violence, or by a continuous application of some irritating cause or agent. For example—the organization of a part may be injured by a severe bruise, and after the lapse of some months, a hardness of a carcinomatous character is found to have arisen in the part injured. Sir Everard Home, in his work upon Cancer, relates two cases, in one of which the disease arose upon the glans penis, in consequence of a violent contusion of that part; and in the other, in the foot from severe pressure and pain occasioned by wearing a tight shoe. In both instances the patients were young and had been previously healthy. In the same manner an ulcer not originally cancerous, such as a venereal bubo in the groin, may, by neglect, bad treatment, or constant irritation, assume, after the lapse of many months, the cancerous character. Or it may happen that frequent irritation of a part, such as the peasantry of Ireland are in the habit of inflicting on their under lips in the act of smoking, from the habit of constantly using short and heated tobacco pipes, may occasion carcinoma in the most healthy, young, and robust persons. Or, as it often happens, the frequent irritation of a pimple or wart, such as occurs in the daily act of shaving, may cause them to assume at length the carcinomatous character.

"2dly. A local disposition to carcinoma may also occur in organs, when they first cease to perform their allotted functions, without any constitutional disposition to the disease. Thus carcinoma chiefly affects the uterus and breasts of women at that period of life in which they cease to be capable of bearing children, i. e. from the 40th to the 50th year. These organs may then be considered useless appendages to the system; and a diminution of vitality or some morbid changes, we may infer, take place at this period in their structure, which render them particularly liable to carcinoma. Dionis observes, that out of twenty cases of cancer

in women, fifteen will be found to occur between the 40th and 45th years.

"But independently of these local dispositions to carcinoma, a strong constitutional disposition exists in others, which is chiefly indicated by a peculiar depressed expression of the countenance, and a pale leaden colour of the skin. In the constitution thus disposed, the disease arises spontaneously and makes rapid progress without showing any disposition to ulcerate or produce those sloughs of the carcinomatous mass which are analogous to the softening of pulmonary tubercles. It also, in general, assails more organs than one at the same time. The lungs become unsound, and in all subjects of this description, in which I have had the opportunity of making post mortem examinations, these organs were found tuberculated. In such constitutions the experienced practical surgeon never thinks of being able to remove the disease by operation. I trust, however, I have sufficiently pointed out under what circumstances carcinoma may be esteemed merely a local disease, and therefore admitting of operation, or other means pointed out in my work upon Cancer, calculated to cure or alleviate it."

PROCEEDINGS

AT THE

EIGHTEENTH ANNIVERSARY MEETING OF
THE
HUNTERIAN SOCIETY.

REPORT,

PRESENTED BY THE COUNCIL TO THE
EIGHTEENTH ANNIVERSARY MEETING
OF THE HUNTERIAN SOCIETY, HELD AT
NO. 4, BLOMFIELD-STREET, FEBRUARY
8, 1837.

(Continued from p. 962, No. 270.)

The Blood and Vascular System.—Some experiments were adverted to, in which a clot of blood reduced to a grumous fluid by comminution, and squeezing through a cloth, coagulated again on the addition of serum from serous cavities, but not when serum of ordinary blood itself was added. Other experiments were mentioned, in which a solution of chloride of sodium produced a similar result; apparently proving that both phenomena depend on the salts

contained in the serum acting on fibrous particles which it holds in solution.

Fibrinous Concretions.—Upon this interesting subject several cases have been adduced from the observations of members.

In the 1st case, there was hypertrophy of the heart, with serous and sanguineous effusion into the pericardium. The carinae were large. The right auricle and both ventricles contained each a large polypus, weighing about an ounce, and attached by three or four peduncles. These concretions were of a pale red colour, solid, firm, and highly vascular.

2nd. A case of endo-pericarditis; the lining membranes and valves were covered with fibrin, which in some parts projected in the form of large masses.

3rd. Here the coagulum was situated in the *appendix auriculæ sinistræ* to which it decidedly adhered: it was firm exteriorly, soft and grumous within. Extensive ossification of the valves and pericardium co-existed with this concretion.

4th. Wart-like vegetations of various degrees of firmness were observed on that surface of the mitral and tricuspid valves which is opposed to the current of blood (rarely, if ever, are they seen on the other surface) together with a body like a half-almond which was attached to one of the aortic valves by its smaller end, and hung thence into the ventricle. All these formations were organized and covered by a very delicate membrane; so as clearly to distinguish them from calcareous deposits, or from cadaveric accretions.

5th. Occurred in a boy *Æt.* 14, who, from a very early age, had been subject to dyspnoea and palpitation. Six weeks before death his face swelled, and his lips became blue. The pulse was at first imperceptible, but the action of the heart distinct and trembling: there was also a projection of this part of the chest. The limbs swelled almost to bursting: diuretics produced little effect; blisters applied to the heels brought away much serum. A fortnight afterwards, gangrene commenced in several parts of the body, and he rapidly sank.

A large mass of pulmonary apoplexy was found in the upper lobe of the right lung, and a smaller mass in the middle lobe. No inflammation was apparent. The heart was remarkably enlarged; especially on the left side. The vena cava superior was filled with firmly organized fibrin adhering to the walls of

the vessel. The tricuspid valves were thickened by calcareous vegetations. The vena cava inferior and vena azygos were large and engorged with blood. The largest branch of the right pulmonary artery was almost entirely plugged with fibrin: the walls of the left ventricle were thick and firm, and the left auriculo-ventricular orifice remarkably small. The foramen ovale was closed, and some ossific matter appeared on the coats of the pulmonary artery.

The diagnosis of this disease of the vascular system is yet a desideratum; but has been attained by observing that dyspnoea, an irregular tumultuous action of the heart, a very weak pulse, cold, and sometimes purple extremities, with a decrease or absence of the natural sound of the heart, had occurred in other cases. The remote, and, in some cases, the immediate cause, was supposed to be rheumatic inflammation: in other instances, calcareous concretions on the valves, with dilated cavities. The exciting proximate cause of one class of these cases was supposed to be an inflammatory state of the blood or cordal lining membrane; in the opposite class of cases, obstruction and consequent slowness in the circulation. Just as in serous inflammation, loose flakes of plastic lymph, after being effused, attach themselves to the membrane, so these concretions which the state of the blood produces, may, when formed, excite adhesive inflammation, and become glued to the walls of the cavity or vessel by a peduncle. Has calomel any control over these vegetations? Two instances of decided *bruit de scie* in the heart's rhythm in connexion with other symptoms, indicated the existence of such formations. Antophlogistics and calomel were prescribed, and those signs ceased.

Aneurism.—A man of middle age and of robust constitution, had long suffered pain at the epigastrium, which was considered dyspepsia. He lost flesh and appetite for six weeks prior to death, which took place suddenly while dressing. A large aneurism of the aorta, immediately above the coeliac and superior mesenteric arteries had burst in two places. An analogous case was presented in a man *Æt.* 35, and of healthy complexion, who however had severe pain in the left shoulder and axilla; no pulsation was observable, — abdominal aneurism was suspected,—and he died suddenly, vomiting a large quantity of blood. The seat of aneurismal changes has been shown to be frequently in the middle coat of an artery,

which, in consequence of a morbid action yet to be fully explained, loses its elasticity, and the vessel gradually gives way. Where the internal coat is even extensively diseased, the form of the external coat is preserved. Three instances of incipient aneurism when carefully examined, appeared to be caused by depositions in the cellular tissue between the internal and middle coats.

Pulsation of Veins.—An ingenious paper was read on this novel subject in Physiology, in order to prove the existence of a safety-valve action in the right ventricle of the human heart. The explanation of such a valve was thus given,—that the veins being influenced by their own number and capacity, by the position of the body, by cold, compression, repletion, and respiration, bring the blood to the right ventricle in varying quantities, and with the most copious influx the cavity may and does become distended, upon which the tricuspid valve is drawn aside for the relief of the lungs.

The venous current was said to be accelerated by gravitation, by the downward pressure of an arterial column weighing against the inert column in the corresponding veins,—by the action of the muscles,—by the motions of the limbs, the pressure of the atmosphere, &c.; but *especially by the ventricular impulse propagated through the arterial tubes, and the capillaries into the veins of every part.* It was not, however, denied that some propulsive power resides in the capillaries. The fact that on immersing the hand in warm water previous to, and during venesection, the jets of blood may be distinctly seen to increase in equal number with each arterial pulse, was adduced as a proof that the impulse of the left ventricle is not always completely expended on the arterial, or even on the capillary system. Under circumstances of unusual vascular excitement, especially with repletion, the dorsal veins of the hand had been seen distinctly beating. Several well authenticated cases were adduced, one of peculiar interest in the person of a young girl who died of purpura hemorrhagica. In her the pulse of the veins was distinct and synchronous with that of the arteries.

Pulsation of the veins appears to be normal, as is plainly observable in the jugular veins of all horses; occasional and dependent on excitement, as seen at any time by plunging the arm into hot water, and it cannot usually depend on a reflux of blood from the right side of the

heart, since it is equally seen if that part of the vessel which is more distant from the heart is firmly compressed.

(To be continued.)

REVIEWS.

Practical Facts in Chemistry, exemplifying the Rudiments, and showing with what facility the Principles of the Science may be experimentally demonstrated, at a trifling Expense, by means of Simple Apparatus and Portable Laboratories, more particularly in reference to those by ROBERT BEST EDE. 12mo. pp. 186. London, 1837. Tegg & Son, and Simpkin, Marshall, & Co.

Ward's Companion to Experimental Chemistry, consisting of Outlines and Directions to the Young Chemist, for performing Experiments by means of Simple Apparatus, with Facility and Success; also intended as a Guide to R. B. Ede's Youth's Laboratory. By JOHN WARD. 12mo. pp. 36.

Mr. Ede's work is very useful to every one devoted to the study of Chemistry. It unfolds the principles of the science in plain and concise language, and illustrates the apparatus by numerous wood cuts. The proposed apparatus may be had at a very trifling expense, and encourage that spirit of ingenuity and perseverance by which difficulties, apparently insurmountable, may be easily overcome.

The work is not an elaborate treatise, but a concise and comprehensive epitome of chemical science. It is evidently the production of a scientific and practical chemist, and is a valuable manual for medical as well as general readers.

Mr. Ward's is what it professes to be, an outline for the young chemist, and a companion to the Youth's Laboratory. It is a horn-book of chemistry, and gives an account of several amusing experiments.

Both the productions before us are published on very moderate terms, and deserve encouragement from the heads of seminaries and all who have the superintendence of youthful instruction.

Medical Essays. By J. HUNGERFORD SEALY, M.D. E. A.B.T.C.D. No. 1. Phthisis Pulmonalis, its History and Varieties: being an Attempt to distinguish those Forms of the Disease which are Curable from those which

are Incurable: with a Novel View of Scrofula and Tubercular Depositions. 12mo. pp. 82. London, 1837. Sherwood & Co.

Consumption Curable. By HENRY CONGREGRE, 8vo. pp. 16. Berger. Price 2d.

Since the successful knavery of the late St. John Long, some members of the medical profession have availed themselves of the gullibility of the public in proclaiming "*consumption curable*." This is an ingenious mode of acquiring practice, for it is well known that consumptive patients entertain the strongest hope of recovery to the last hour of their existence. It is also to be remembered, that they languish for weeks or months, and sometimes for years, after having been pronounced incurable by the ablest physicians; during which period the consumption curable people stick to them like true leeches, and pick their pockets while a single fee remains. When death approaches, the impudent and unprincipled curers very gravely declare, "we were called in too late; but if any other member of the family should be attacked, and remember the disease is hereditary, though we have cured thousands, pray call us in as early as possible, and we shall attend while you are able to pay us a guinea."

Thus Dr. Sealy professes to cure six out of every ten cases; Dr. Ramadge's claims are notorious; and the benevolent Henry Congreve advertises to the world, "Just published, 32 columns, price 2d. CONSUMPTION CURABLE. The best means of arresting this hitherto fatal malady. From the extreme variableness of the atmosphere of England, there is not an individual whose benefit is not consulted in this pamphlet. It is introduced at the astounding low price of 2d. from motives of benevolence to the afflicted. The asthmatic and those afflicted with harassing coughs, the nervous and dyspeptic, the mother, and the nurse, will find here advice of paramount value."

We hastened to peruse this benevolent pamphlet, and found it nothing more or less than a series of puffs of different nostrums sold by the author, who is a chemist or druggist. Such are the real motives of benevolence to the afflicted!

The London Medical

AND

Surgical Journal.

Saturday, April 8th, 1837.

PRIVILEGES OF THE MEDICAL PRESS.

IN commencing a new volume, it affords a favorable opportunity to make some observations on the extraordinary changes which have taken place in the tone of the medical press since the commencement of this journal. About that period it may be said that the medical profession, unlike that of all others, was exercised and carried on at the pleasure and free will of its members, and being under no public surveillance or control, every possible misdemeanour, and all irregularities of conduct towards the public, met with no check.

Whilst the public acts of political men, of the warrior, and the divine, were subject to discussion and animadversion in every newspaper, not only were the most fraudulent abuses recognized by the medical corporations, but the greatest enormities were committed by the physicians and surgeons of our public hospitals.

The attacks which were made in the *Gazette of Health*, by the late Dr. Reece, on the constituted authorities, and the exposures which were also occasionally made of the mal-practices of individuals, which were afterwards boldly followed up in the *Lancet*, created such an excitement in the minds of the corruptionists, that the first attempt was made to crush the press, and at once stem the torrent which had begun to flow into the Augean stables. That memorable occasion must be fresh in the recollection of some of our readers, when several of

those individuals who were likely to suffer most from public exposure, subscribed a sum of money, in the hope of finding relief in courts of law, and further, if possible, hurling to destruction the authors of those exposures which they well foresaw would sooner or later lead to what *they* very justly considered most alarming changes in the state of medical polity.

Having completely failed in these projects, being baffled on every occasion when they had the effrontery to exhibit themselves in a court of *justice*, and public interest increasing daily by the exposures which were made by the medical press, then, and not till then, were they convinced of the necessity of having recourse, as a last resource, to the establishing of a periodical of their own, which would enable them to have a weekly opportunity of upholding all that was fraudulent and corrupt, of distorting and concealing the truth, and of propagating falsehood! To accomplish so desirable an object, a liberal subscription was entered into, to start a journal on these principles; and which periodical, it is but justice to admit, has most rigidly and conscientiously performed the duties imposed upon it. In this state of things, the struggle which was made to expose and vilify the mischievous practices of the corruptionists, and the convulsive efforts which were made to screen and defend their frauds and impositions, led the contending parties to use expressions and employ language as severe as the limits of the law would permit; and in some cases, we must admit, far beyond what good taste would have dictated. In this great struggle of medical reform, we are proud to aver that in many instances we have availed ourselves of the *privileges* of our contemporaries, and we trust that the efforts which we have

made to ameliorate the condition of our professional brethren, more particularly that of the general practitioner, have not been unavailing; and we do also trust, that in the performance of this important duty, we have never allowed our feelings to indulge in those low personalities and vulgar aspersions which so abundantly adorn the pages of the subscription gazette.

Whilst the prospects of the future must ever be a matter of difference of opinion, we may always derive valuable lessons from the events of the past; and no more important one presents itself than the manner in which the medical press, for the last few years, has burst the narrow bonds which were supposed, by the corruptionists, to fetter it, by boldly and manfully exposing the abuses we have alluded to, and holding up to public odium the supporters and abettors. If we glance through a volume of the early medical journals, a degree of tameness and subserviency will be found to pervade its pages, ill calculated to expose and correct the enormous abuses in hospital government and medical instruction, which were universally admitted at the time to exist. These may be attributed to many causes, but in particular to a want of moral courage, and an ignorance of the extent of power which the medical press possessed, added to these the direct interest which some of the hospital purms had in the *circulation* and *sale* of the journals.

When baffled in their appeals to courts of *justice* (in which they often cut so contemptible and sorry an appearance,) the idea seized them as the last resource to start an opposition gazette, and thus demonstrated their *admirable consistency*, by opposing the enemy with the same, but inferior, kind of weapons, against the use of which they had for-

merly so loudly, but ineffectually, inveighed. It was on the birth of this *Medical Gazette reform clog*, that the full extent of the privileges of the medical press was practically ascertained; the abuse, personalities, and misrepresentations it weekly emitted, led us in exposing them, to use similar language, on some pressing cases; and notwithstanding that we sometimes received strictures upon our new style, in private letters from some of our most valued supporters, yet, to meet the *intellects*, and accord to the taste, of our abusive opponents, we descended to the low ground they had taken possession of; and thus disadvantageously circumstanced, we had to watch with a keen eye the movements of an enemy, proverbially supported in its rear by the contributions and pecuniary support of a knot of individuals, whose surreptitious reputation and position in medical society, demanded the most energetic and active movements, upon their parts, to maintain.

How far the MEDICAL REFORM CLOG has effected the object for which it was brought into existence, we shall in a future number examine; and at the same time it will not only be interesting, but highly instructive, to make selections from the several medical journals in illustration of the *privileges of the Medical Press*.

THE MIDDLESEX HOSPITAL.

The Governors of the North London Hospital have been well rewarded by having made the first effort to reduce the exorbitant demand which had been so long made by all the recognised Hospitals, on the medical student. When it was first proposed to admit students to the North London Hospital at a reduced price, it created the greatest consternation and

dismay amongst the old monopolists of Lincoln's Inn Fields; and so mortified were many of the members of the Council on this occasion, that it was extremely doubtful whether or not the College would have granted a recognition to the New Hospital. The result has been, as the well grounded feelings of the Council anticipated, that an overwhelming mass of students poured in at the expense of the other Hospitals, more particularly those of Westminster, Middlesex, and Smithfield.

Such has been the effects of the reduction of the admission fee to the North London Hospital, that it has become a subject of grave deliberation amongst the medical fraternity of other institutions, how far it would be expedient for them to reduce their prices; and there is a general impression that the medical officers of the Middlesex will set the example next season; and if they do so, there is no doubt but that they will receive more money than they have done last, by doubling the number of students to the medical and surgical practice of the hospital.

Should the mock-liberals of Gower-street adopt the narrow-minded policy of closing the hospital doors against all students, who do not attend the classes of their own schools—a proceeding which was lately contemplated—then will the doors of the Middlesex Hospital be thronged, and the medical staff fatten and prosper. We would advise our friends at the Westminster to stick to the old price, as it is of importance to uphold the *dignity* of the hospital, and as no diminution in price could be reasonably expected to increase the number of students.

FAMILY CORRESPONDENCE.

Progress of an Irish Medical Student.—His Account of his Journey and the Metropolis.—His Introduction and determination as to Medical Schools.—His Father's Reply.

My dearest Father,—You will be pleased to know that I have arrived safe at my journey's end. I got here at half past seven o'clock yesterday morning, after having suffered much, as the night had been very cold, and I was the only outside passenger. I left my trunk at the White Horse cellar, and having had a comfortable breakfast, which cost me eighteen pence, I immediately started to look out for a lodging; and here I am, having taken up my quarters in a small room, two pair front, opposite No. 104, Great Russell Street, Bloomsbury, where please to address all my letters. After I arrived at Cork, I waited on your old college companion, Doctor M—, who invited me to dinner, and will answer your consultation about the Twin case by return of post. He refused the fee for his opinion, saying, "Keep it. Thomas, you will find plenty of use for this and many more before you get emancipated from the clutches of my old friends in Lincoln's Inn Fields." I picked up a few letters of introduction to some of the lions here, concerning which I shall tell you after I have delivered them. I sailed in the "Herald" steamer, and took a deck passage, the weather being promising; but, unfortunately, there was such a number of pigs on board for the Bristol market, and my becoming very sick, it was altogether a scene of dirt and confusion. The only person who knew me on board was Mr. —. He recognised me from my likeness to my mother, and we had a long *confab* about it. There were several students on board, all bound for the London Schools; but, like myself, they were all at sixes and sevens where to go to get the thing best and cheapest. We all agreed it would be best to make a survey of the different Schools, hear the different Professors, and have a meeting in London to compare notes.

When I got to Bristol, I gave the steward half a crown, besides the passage money, and he recommended me to a cheap lodging for the night. I did not remain in Bristol longer than twelve hours, as all my anxiety was to get to London as soon as possible, which I accomplished on the outside of the "Accelerator," for one guinea, including guards and coachmen.

No. 1.

I was in several lodging houses here, but could not find a decent room in a respectable street under eight shillings a week. I could have got a room in Hadlow Street, Burton Crescent, close to the Gower Street School, for six shillings, or even less; but the neighbourhood is so disrespectable, that I knew you would be more dissatisfied than myself, and not grudge the additional two shillings, for the sake of appearances. In addition to the hire of the room I have to pay three pence a day for fire, candles not included, two pence for cleaning each pair of boots, washing will not cost me more than one shilling a week, as what are called "black tommies" are chiefly worn here. Breakfast at home will not cost me less than two pence halfpenny every morning, and I can dine well out at a *slap bang eating house*, or procure the needful at the *Holborn ham shop*, for eight pence, including a pint of porter. These, with a shilling a week to the servant of the lodging house, will include all my expenses, provided you can get smuggled to me the whiskey and potatoes, neither of them is worth eating or drinking here, and the price of the whiskey, bad as it is, is *twenty-one shillings a gallon!* and, (would you believe it?) they sell the potatoes by the *pound!* Now, my dear parent, I will write to you every thing that occurs, and all that I see and hear; and, God knows I shall have plenty to do and think about to prevent me getting into difficulties, for it is a larger place than even I imagined, and all the people, young and old, seem to me very abandoned and profligate. If you could get *Garrett Standish* to frank my letters, it would save expense. Give my affectionate love to my mother and dear sister. Tell Pat that he is a much happier fellow where he is, with his gun in his hand, and Ponto at his heels, than I am away from them all at home. No one knows the comforts of a father's house until circumstances compel them to quit their "home, sweet home." Tell *aunt Sarah* that I won't forget all the commissions. When you next see the *Morgans*, tell *Emily* not to forget. From what I have heard here, I don't think I will have enough of money to pay the class fees. I'll write to you what more I shall want, and give you a list of the expenses. Believe me, beloved Father, your very dutiful and affectionate Son,

THOMAS.

P. S. This letter is enclosed in a frank of the honourable Radical member for

Finsbury, who says he remembers you and has kindly promised to give me his friendly assistance and advice, which will be great things to have. Had you much sport on the 20th?

Great Russell Street, Bloomsbury,
Sept. 27th, 1836.

Kilballymacalogue, Blarney.
Oct. 8th, 1836.

My dear Tom,—I have just read your letter, and must leave your mother to tell you all our domestic news, as I am called to a case of emergency; and if I don't attend to it immediately, somebody else that you know will. We were well pleased that you had borne your journey so well, and I have the fullest confidence in your future conduct, as your mother's example and precepts will, I trust, always guide you, and the natural warmth of your heart will induce you often to think of us all at Kilballymacalogue. Let me again impress upon you the necessity of not entering to any school, or feeing any hospital, without due consideration. In the choice of an hospital, Mr. Wakely's opinion would, to me, be decisive. He has no self-interest to serve, and must appreciate the good and the bad of them all. I enclose you letters to Sir Astley Cooper, Sir Benjamin Brodie, Sir James Mc'Grigor, Sir William Burnett, Sir Stephen Hammick, Sir Charles Scudamore, who got the thousand pounds for coming over to visit the late Marquis of Waterford, Sir Henry Halford, who, by the bye, is not known to any body here, and Sir Matthew Tierney, who has, I understand, become too great a man to pay attention to introductions from any of his old Cork relatives and cronies. James Johnson, also, does not acknowledge his countrymen; but I'll see what I can do to get you a letter to Doctor Rumadge, who is said to have great influence at the College of Physicians, and can procure you a ticket of admission to their valuable conversations and tea parties. Doctor Jones Quain will, I am sure, be both kind and useful to you; and, although he is not now a professor himself, his brother Dick is still at University College, who will, I have no doubt, be attentive to you, for old acquaintance sake. Tell him how glad all friends are to hear he is getting on so well. Dr. Bankhead is still in France, so that a letter to him can be of no use. The letters to Travers, Lawrence, Bransby Cooper, Elliotson, Carswell, Liston, Anthony Todd Thomson, Mc'Cleod, Cummin,

Golding, Howship, Guthrie, Scott, Mayo, &c. &c., you can deliver at your leisure. In delivering your letter to Mr. Todd, the professor of Anatomy at the King's College, ask permission to see the building, and also Somerset House, which was a very fine place in my day; at the same time, be cautious not to talk on political subjects with him. With all these men, when you deliver your letters, it is absolutely necessary for you to recollect the old maxim, "*eyes open, ears listening, mouth shut.*" I will send you whatever money you may require, trusting to your discretion and economy; and have only to request you will not run up bills, but pay ready money for every thing. When next you write, tell me the School you have determined to enter to, also the Hospital you have selected to walk, and which, if any, of your other letters was of any service to you. Avoid the company of idle young men, and stick to your pursuits, my dear Thomas, when, after two years residence, I hope you will pass your examination with credit, and return to your happy home. I have no doubt but I have interest enough to get you into the ——— Infirmary, where there must be a vacancy in a few years; and I need not tell you what a stepping stone to fortune this would be. Say nothing about this, as others are on the look out; but I have little doubt of your success, when the vacancy occurs, so keep your eye on the certificates. All join in affectionate love, particularly dear Tom, Your loving Father,
PETER ———.

HOSPITAL REPORTS.

NORTH LONDON HOSPITAL.

Disease of the Knee-Joint—Removal of the Thigh at the Hip-Joint.

Tuesday, March 28, 1837.—A little girl, between the ages of five and six years, submitted to the removal of the thigh by the double flap operation, for disease of the knee-joint.

Mr. Liston removed the limb in less than two minutes; he was assisted by Mr. Richard Quain, who compressed the femoral artery in his usual steady and composed manner, so much so, that without exaggeration an ounce of blood was not lost; indeed, so long as an assistant well acquainted with topographical anatomy, and of firm nerve, can be procured, the tourniquet may be altogether dispensed with in these operations. Con-

sidering the screaming which the little patient made before the operation, she bore it altogether with much nerve. An abscess, the extent of which towards the groin, which unfortunately had not been detected before the operation, was cut into, from which a quantity of pus was discharged. When the limb was removed, it was then ascertained that this abscess had communicated with the knee-joint, the interior of which was filled with pus; there was also extensive caries of the inner condyle of the femur.

ST. GEORGE'S HOSPITAL.

Thursday, March 30, 1837.—**LITHOTOMY.**—Mr. Babington, in the presence of a number of students from various quarters of London, removed a middle-sized stone from the bladder of an adult. The incision was made into the bladder by the lateral method, with a knife and grooved staff; but on introducing the forceps a prolapsus ani occurred, which pulling down the inferior fundus of the bladder, rendered it impossible to extract the stone with the ordinary instrument. After a few minutes' delay, a curved forceps was procured, and the stone removed with little difficulty. Messrs. Keate, Hawkins, Cutler, Walker, and Sir Benjamin Brodie were present.

Necrosis.—Removal of the Sequestrum.

Sir Benjamin Brodie next proceeded to trephine a necrosed humerus of a young lad for the purpose of removing the sequestrum. Incisions were made of sufficient extent to allow of the application of the crown of the trephine, and after much sawing, and a great deal of difficulty, a portion of the shaft of the old humerus, from five to six inches in length, was removed. This is the second case in which a very serious operation has been lately performed by Sir Benjamin Brodie, merely for the purpose of removing a sequestrum of a necrosis bone. We say serious, because we deem it proper to state, in the former case, where Sir Benjamin operated for a necrosis of the tibia, the patient died in three weeks. We doubt exceedingly the propriety of these severe measures. The patient, also, whose leg Sir Benjamin Brodie amputated, an account of which we gave in this journal, became a victim to the operation. So many fatal and unsuccessful results of operations as we have almost daily an opportunity of observing

in the London hospitals, ought surely to be a caution to "young surgeons," as well as to "veterans," and ought to make us careful in extolling the advancement of modern surgery.

Removal of the Great Toe and Part of its Metatarsal Bone.

After the completion of the last operation, Mr. Cæsar Hawkins proceeded to remove the great toe, with part of its metatarsal bone, from the foot of a boy aged thirteen years, afflicted with strumous disease. Two flaps were formed from the dorsal and plantar aspects of the foot, and the metatarsal bone was divided near its tarsal extremity with the large bone forceps called "*The Lion Forceps*," a faithful representation of which is to be found in Scultetus's "*Armamentum Chirurgiæ*." Mr. Hawkins was in no hurry about the operation, which was not completed for eight or ten minutes, although the patient suffered great pain, saying to the operator, "you make me sweat." He did not pursue the *race-course* plan of operating,* and by not disarticulating the metatarsal bone he thus preserved the attachment of the peroneus longus muscle, and also that of the tibialis anticus; a proceeding in the performance of this operation which reflects the greatest credit upon the anatomical and physiological acquirements of Mr. Hawkins.

Operation for Lithotomy—No Stone.

The boy who was operated upon for stone, and in whose bladder no stone was found, is recovering. The little fellow is still in hospital in good spirits, and labours under symptoms of calculus. There are two other patients with stone in the bladder, who are undergoing the necessary preparations. We advise the house-surgeon to keep a sharp look out after them, as it is whispered that they may find their way into the *trap* of the North London.

ST. BARTHOLOMEW'S HOSPITAL.

Stricture—Abscess in Perineum and Prostate Gland—Effusion of Urine—Death.

Edward Walker, aged 59, admitted into St. Bartholomew's Hospital, November

* See last Journal, p. 945.

5, 1836. He has suffered from stricture in the urethra for thirty years; has had difficulty in making water during the same period, and this difficulty was greatly increased, in consequence of which he applied to a medical gentleman, who made an attempt to pass an instrument for him, but without success: and he bled very much after the operation.

On the evening of the same day, he suffered great pain in the perineum, and could only pass a small quantity of water. He did not again seek medical advice, until two days previous to his admission, when another unsuccessful attempt was made to introduce an instrument, after which only a very few drops of urine followed.

Saturday, Nov. 5th, 9 o'clock A.M.—He now states that he has not made water for a week. There is considerable fullness of the perineum, with great pain of that part, and some pain of the scrotum. His countenance is expressive of great anxiety. Tongue covered with a dark brown dry fur; pulse quick, and small. An attempt was made to introduce a silver catheter, which came away much blackened and discoloured, and about eight ounces of extremely foetid urine followed the removal of the instrument. He was placed in a warm bath; in which he remained about twenty minutes, and obtained great relief.

Mr. Earle saw him about one o'clock in the afternoon, and after unsuccessfully attempting to introduce a catheter, he cut down upon the urethra through the perineum, with a double edged scalpel, laying open the canal immediately behind the bulb. Some of the same foetid urine slowly escaped. On attempting to pass a catheter through the wound into the bladder, it passed evidently out of the canal of the urethra into a boggy undefined space, having bristles extended across it in all directions, and which gave the sensation of a cavity in which there was breaking down of cellular structure. With much difficulty, a gum-elastic catheter, without a stilette, was introduced into the bladder. This was retained in position by proper bandages. He takes a saline mixture with antimony.

7 P.M.—He expresses himself much relieved by the operation; healthy urine passes freely through the catheter; he complains of no pain; tongue moister, but still much furred.

6th.—Has slept well (the first sleep he has had for some days past); urine passes freely, both through and at the sides of

the catheter, but he complains now of great pain in the scrotum and left groin. Fomentations ordered to these parts. Tongue remains as yesterday, as does the pulse. Bowels are freely opened.

7th.—Has had rigors at intervals, though he has continually dozed since yesterday. The catheter is removed from the wound, as the urine flows freely past it; the pain in the scrotum and groin has much subsided, though the scrotum is greatly enlarged and livid. A large diffused swelling, with considerable redness of the integuments covering it, was observed in the left lumbar region, extending down to the brim of the pelvis. A puncture was made into this with a lancet, and some bloody urine escaped; and minute punctures were also made into the scrotum. He was ordered to discontinue the antimony, the action of which was transferred from the skin to the bowels. Wine and brandy were ordered to be administered frequently, and fomentations to be applied to the loins and scrotum.

8th.—Urine continues to escape through the wounds in the perineum and loins. He lies in a comatose state, and is rapidly sinking.

He died on Wednesday the 9th, having been quite insensible during the last twenty-four hours.

On examination after death, the urine was found to have completely infiltrated the cellular tissue of the perineum and scrotum, the left groin, and to have extended upwards to the loins, and even to the axilla, on that side; but no urine was effused into the cavity of the abdomen or pelvis. The bladder was much thickened, and the mucous membrane in an ulcerated state. The prostate gland was slightly enlarged, with an abscess in its substance. The urethra was very much diseased, the first four inches being the only part assuming at all a healthy appearance. There was great difficulty in following even the track of the remaining part, which appeared to have given way about the membranous or muscular portion. Opposite to this spot there existed an abscess in the perineum, communicating with the urethra, and also with that in the prostate gland. It was also evident that several false passages had existed, one of which, after pursuing a course of about two inches, perforated the urethra again. The kidneys were healthy, but the ureters much dilated.

It would have been exceedingly interesting to have discovered whether the urethra was ruptured primarily, in conse-

quence of ulceration commencing within its canal, or whether this was secondary to the prostatic and perineal abscesses. From the condition of the patient when he entered the hospital, and state of the parts after death, the solution of this difficulty was rendered impossible. — *Medical Gazette.*

HOME CIRCUIT

KINGSTON, MARCH 30.

(Before Chief Justice TINDAL
and a Special Jury.)

THE KING V. CARRINGTON AND OTHERS.

This indictment was preferred against the defendants, Benjamin Carrington, Benjamin Nelson Linwood, Frederick Musgrove, James Tomlinson, Thomas Harris, and Edmond Edmonds, all medical students of Guy's Hospital, for a riot, and also an assault upon John Williams and Thomas Moysey, two of the porters, and Mr. Richardson, a student of St. Thomas's Hospital, on the 16th of December last. Mr. Harris did not appear.

Mr. THESIGER, Mr. CLARKSON, and Mr. CHANDLESS conducted the prosecution; Mr. PLATT, Mr. CHANNELL, Mr. TURNER, and Mr. RULOCK defended.

There was a great mass of evidence adduced on both sides, and the trial consumed considerable time in its investigation; but the details may be condensed into a brief summary.

It appeared that the alledged riot and assault occurred on the 16th of last December, on the occasion of an operation of lithotomy which was about to be performed on two patients at St. Thomas's Hospital. On the Friday preceding the 16th there had been some disturbance among the students, and in order to prevent a repetition of it, Mr. Nash, the steward of St. Thomas's, placed three porters at the doors leading into the operating theatre, and gave them directions not to admit any pupil unless he showed his surgical practice ticket. They were also directed to place the students in the places appropriated to them—namely, the dressers in the lower rows, and the students in the upper, the area being kept for the operating surgeons and their dressers only. It had not been usual to demand the practice tickets previous to admission, and the dressers were on ordinary occasions allowed to occupy the area; but the governors of St. Thomas's Hospital, feeling that it was only a liberty

granted by courtesy, determined, in consequence of the previous disturbance and tumult, to enforce the right which they contended they possessed, of excluding those who did not show the authentications of their right of admission. Accordingly, on the board announcing that the operation would take place, and which was placed in the room of both hospitals, they affixed a notice that every gentleman who wished admission must bring his ticket with him. At a little past one on the day in question, according to the evidence adduced on the part of the prosecution, Mr. Carrington came to the door and demanded admission. Having shown his ticket, Bull, the porter, who was placed at the outer door, called out to Moysey, another porter stationed inside the door, to let the gentleman pass, as he had shown his ticket. Moysey opened the door, and Mr. Carrington entered, but he had no sooner got in than he raised up his arm and struck Moysey. Williams, another porter stationed at the door leading into the area of the theatre, saw him give the blow, and asked why he had struck a man in the execution of his duty? To which Mr. Carrington replied, "If you are not very civil I will strike you." Williams told him he had made an assault upon his fellow-servant, and if he persisted in such behaviour, he would not allow him to go into the theatre at all. Mr. Carrington immediately rushed past Williams, and tried to get in; but Williams caught hold of him and stopped him. Mr. Linwood at that moment came in and seized Williams by the collar, and struck him two or three times. Williams, who, besides being a porter of the hospital, was a constable, pulled out his staff, showed him he was a constable, and desired him to desist from striking him while in the execution of his duty. No attention, however, was paid to what he said, and Mr. Carrington and Mr. Linwood seized hold of him, and tried to throw him down. He caught hold of Mr. Linwood's leg, and prevented his being thrown. Both Mr. Carrington and Mr. Linwood then left him, and rushed into the body of the theatre. Williams followed them, and pointing out the seats appropriated to them, told them they had no right where they were. They replied "They would see him — before they would go there; they had a right to be where they were, and they would stop. He told them if they would not go out quietly he must get assistance and put them out. He then called Moysey, and they tried to put them out, but could not

effect it. The outer door was then forced open, and a crowd of students rushed in. Mr. Nash, the steward of the hospital, and Mr. Travers, who was to perform one of the operations, then entered the theatre. There was a great noise of hissing, howling, and all sorts of clamour, and Mr. Nash and Mr. Travers addressed the students, and endeavoured to persuade them to desist from making the disturbance. Williams went on to the landing-place, and immediately afterwards there was a general rush from the theatre, and several voices shouted out "Over with him; over with him!" The crowd then pressed upon him, and forced him upon the rail of the banisters, and, taking hold of his leg, tried to put his head downwards. The top of the banisters was 30 feet from the ground. Mr. Richardson, a pupil of St. Thomas's, having noticed the conduct of the parties, followed the defendants, and, seeing the treatment of Williams, he got hold of him, and succeeded in forcing him away from the students into a ward. Mr. Richardson upon that was immediately attacked and struck; and Mr. Musgrove it was stated, pinioned his arms behind, and, after having tried to throw him down, took him up in his arms, and they were both forced by the crowd into Henry's ward, where Mr. Musgrove threw him upon the ground. While lying there he received several kicks, and, in self-defence, he seized hold of the poker, but was prevented using it by one of the police, who were afterwards called in. The tumult continued between three and four hours, during which time there was a constant hissing and hooting. Mr. Nash, Mr. Travers, and Mr. Tyrrell, having in vain tried to appease the noise, the police were sent for, and the operation was deferred.

The above is the substance of the evidence for the prosecution. On behalf of which it was contended that the defendants, with other students, had acted upon a plan of making a riot, in consequence of their being refused admission to the operation unless they produced their surgical practice tickets; they entertaining an opinion that they had a right to admission to the theatre whenever an operation was performed, and that the dressers by right could remain in the area for the purpose of witnessing it. The premeditation was asked to be inferred on account of certain expressions, which had been used during and before the disturbance, such as, "Where are Grainger's men?" and "The police are outside the door

waiting for you, Carrington and Linwood; but if they are, — them, let us upset them." And previously to the time at which the operation was fixed to take place, a student of Guy's heard some one say in the dissecting room at that hospital, "Who is going up to St. Thomas's to see the row there?"

The substance of the evidence on the part of the defendants, which was detailed by several medical pupils of Guy's Hospital, who were present on the occasion in question, was that there was no premeditated plan of riot; but, on the contrary, the students complied with the regulations of the hospital by producing their practice tickets when asked for. The disturbance arose from the manner in which the porters behaved towards the different gentlemen; that Williams was very offensive, and told Mr. Hemming, after he had asked him for his ticket, and that gentleman had expressed his surprise at being asked for it, that if he did not produce it he must forcibly thrust him out; that when Mr. Carrington was proceeding from the outer door of the passage to the inner door, Moysey put his hand upon his shoulder, and said, "You can't go there, Sir; you have no right." Mr. Carrington pushed him on one side, and went into the area, upon which the porter, Williams, followed him, took him by the collar and swung him round, and then pulled him out through the area door. While Mr. Carrington and Williams were scuffling, Mr. Linwood passed, and Williams immediately left Mr. Carrington and took hold of Mr. Linwood by the collar, in the same way as he had seized Mr. Carrington. That Williams cut Mr. Carrington on the face with his staff, and made it bleed. That as soon as Mr. Travers and Mr. Nash entered the theatre, Mr. Linwood and Mr. Carrington went up to them, and complained that they had been ill-used and assaulted by the porters. That when the police came Mr. Linwood gave Williams into custody. They attributed the disturbance entirely to Williams, and stated that had he been removed, it would have immediately ceased. There was no disrespectful conduct meant or shown towards Mr. Travers or Mr. Tyrrell; but the hissing and hooting was applied to Williams, who, after having committed the assault upon Mr. Carrington and Mr. Linwood, went into the theatre, and looked about in a very impudent manner. The students were much excited from the treatment they received. It was

stated by all the pupils who were examined as witnesses, that they were in the habit of attending the operations, but had not been called upon to produce their surgical practice tickets. Those who were, or had been dressers, occupied the area of the theatre.

Mr. Bransby Cooper also stated that when he was a dresser, such was the practice; he had known it, however, departed from upon one or two occasions. He further stated that Mr. Musgrove was his dresser, and he considered him very gentlemanly, quiet, and attentive to his duties.

Mr. Morgan, surgeon at Guy's Hospital, gave similar evidence with regard to Mr. Linwood, who had been his dresser. Mr. Linwood had won a prize for the best essay on ophthalmic surgery.

Mr. Ward deposed to the same effect, relative to Mr. Edmonds.

Chief Justice Tindal, in summing up, told the jury they must determine upon the evidence they had heard—first, whether the defendants had been guilty of a riot—and, secondly, whether all or any of them had been guilty of an assault. With regard to any supposed right of admission of the students to the operations at the hospital, that could not be determined by the present question; because whether the right existed or not, the law would not sanction their enforcing it in the manner in which the defendants had been represented to have acted. And having the right, they would be equally amenable for a breach of the law, as if they possessed no right.

The jury retired, and were absent for a quarter of an hour. They then returned with a verdict of *acquittal* for the riot, and of *guilty* as against Mr. Carrington, Mr. Linwood, and Mr. Musgrove, for the assault upon Williams.

The defendants were then called up for judgment; and

The Learned Judge addressing them said—You have been found guilty, by the verdict of a jury of your country, of an assault upon John Williams, of an aggravated nature, and it gives me great pain to pass the sentence of the law upon young men of education, and in your station of life. I shall not attempt by any observations of mine to aggravate the nature of the case, because I doubt not your own reflections will be more severe monitors than any remarks I can offer. It is necessary, however, to hold out to the public that offences of this nature must be put down by the strong

hand of the law; but when I look at your youth and inexperience, I am induced to think that circumstances of excitement prevailed upon you to act in the manner described. I shall take care, therefore, not to pass a sentence that shall affect you with any pain from the nature of the punishment, or tend in any way to blight your future prospects in life. Taking all the circumstances of the case into consideration, the sentence of the Court is, that each of you pay a fine to the King of 40*l.*, and enter into your own recognizances for two years to be of good behaviour, and that you be imprisoned until such fine be paid and such recognizances entered into.

The terms of the sentence having been complied with, the defendants were discharged.

The trial occupied the Court for nearly twelve hours, and seemed to excite considerable interest among the members of the medical profession, a great number of whom were present.

MISCELLANEOUS

MEDICAL BOTANY.

COMMUNICATED WITH THE VIEW OF CALLING THE ATTENTION OF NATURALISTS TO THE MEDICINAL PROPERTIES OF PLANTS.

By Dr. CASTLE.

XIII.

SHOWY-FLOWERED MESNA.

An elegant and lofty tree, with very showy flowers, a native of the East Indies. It is the *Mesna speciosa* of Choisy, and belongs to *Monadelphica*, *Polyandria* of Linnæus, and to the natural order *Guttifera* of De Candolle. In altitude it often exceeds fifty feet, and being planted near habitations, its foliage affords an excellent shade. The leaves are long, linear-lanceolate, and rather acute. The flowers are odiferous, about the size and shape of those of the sweet-brier, axillary, solitary, with a calyx of four unequal permanent sepals, and four white rounded regular petals; stamens indefinite, connected at the base; filaments filiform; anthers erect, two-celled, bursting lengthwise at the sides. Style short, crowned by a thick concave stigma; ovary two-celled; each cell containing two erect ovules. The fruit is reddish, and wrinkled when ripe, with a

rind like that of the chesnut, containing three or four seeds, which are of the size, shape, substance, and taste of the chesnut. The tree is much cultivated, according to Rhude, in Malabar; produces fruit when of six years' growth, and is said to continue for three centuries after. The dried flowers are frequently used with the white sandal-wood, to impart an agreeable fragrance to cerates and other compounds. The bark, wood, and roots are sweet-scented and bitter, and might be advantageously introduced into practice as an agreeable aromatic, particularly for cases which will not permit of the use of astringent bitters.

I am not aware of the Showy-flowered Mesna having been cultivated with us, but Don, in speaking of the family, considers it worthy a place in every collection of stove plants. *BIP. REF.* — *Choisy M.SS. ex De Cand. prod.* 1, p. 562. *Rhude, mal.* 3. p. 63. *t.* 53. *Don syst.* 1. p. 622.

XIV.

STRONG-SCENTED POLANISIA.

This pretty annual plant, the *Polanisia graveolens* of Rafin (Cleome dodecandra var. Canadensis, *Lin.*) is a native of North America. It belongs to the natural order *Capparidæ* of De Candolle; but from the number of stamens varying from eight to twelve, its exact position in the Linnæan arrangement is not definite; it is usually placed under *Dodecandria Monogynia*. The whole plant, which is commonly above two feet high, is beset with glandular hairs; the leaves are trifoliate; the leaflets elliptical-oblong. The flowers, which appear from July to September, are small and pinkish; the calyx four-sepalled and spreading; petals four; and the seed-vessel an oblong silique, which is narrowed at the base, glandularly muricated and pubescent. The root is reputed in America anthelmintic. Introduced into our botanic gardens in 1820; but like many other tropical plants, it needs a warm and sheltered situation. *BIB. REF.*—*Raf. journ. phys. aout.* 1819. p. 98. *Bart. fl. amor.* t. 22.

XV.

BILIMBI OR CUCUMBER TREE.

The Cucumber Tree, or as it is popularly called in Malabar, "Bilimbi," is a native of Goa and many other parts of the East Indies; and is now cultivated

in several provinces of South America. It is systematically named, the *Averrhoa Bilimbi* of Linnæus, and belongs to his *Decandria, Pentagynia*, and to De Candolle's *Osculidæ*. In size it varies considerable, sometimes being scarcely six feet high, sometimes near to twenty, and is furnished with but few branches. The leaves are alternate, consisting of from five to ten pairs of ovate-lanceolate, entire, smooth leaflets. The flowers are reddish purple, disposed in racemes, rising from the trunk; calyx of five pubescent sepals, which are more or less joined together at the base; petals five, with oval-oblong limbs; stamens ten; ovary angular; styles five, permanent. The fruit is oblong, somewhat like a small cucumber, with a thin, smooth, green rind, five-celled, with a few seeds in each cell adhering to the central angle; seeds not unlike those of the cucumber, without an aril; embryo straight, in a fleshy albumen. The fruit abounds with a highly grateful sub-acid juice, which being properly prepared with sugar, forms a very valuable drink for persons labouring under febrile, bilious and other disorders.

The Bilimbi introduced into our stove houses in 1791, thrives well in a light sandy loam: flowers from May to July; and ripe cuttings will strike root freely in sand under a hand-glass. *BIB. REF.*—*Lin. spec.* 613. *Cav. diss.* 7. t. 219. *Rumph. amb.* 1. p. 115. t. 35. *Don. syst.* 1. t. 121.

COMPLETE MEMOIR ON

PHTHISIS LARYNGEA,

EXTRACTED FROM THE UNEDITED WORK OF MESSRS. TROUSSEAU AND BELLOC, FOR WHICH A PRIZE WAS AWARDED BY THE ACADEMY OF MEDICINE IN PARIS.

What is meant by Phthisis laryngea? What are its Organic Alterations? its Causes? its Species? its Termination? What is its Treatment?

CHAPTER I.

ON DEFINITION.

The word *phthisis* signifies consumption. Any organic alteration which may give rise either to marasm, or hectic fever, is, properly speaking, a *phthisis*, to whatever cause that disease may be attributed.

Some modern authors have exclusively applied the word *phthisis* to a tuberculous affection of the lungs; in our opinion this is an error, and the Academy seems to agree with us in this respect. It is evi-

dent, from its association of the words Phthisis Laryngea, that allusion is made to the chronic disease of the larynx, which if not exclusively, at least principally, gives rise to hectic fever and consumption.

The exact definition of Phthisis Laryngea should therefore be chronic affection of the larynx, which may also give rise to consumption.

But the disease to which we now give our attention is seldom followed by actual consumption, as the anatomical disposition of the parts often causes death by suffocation. The patients may, nevertheless, be considered as victims, as, without the alteration of the larynx, suffocation would not have taken place; and then if this disease had not caused the obstruction of the air passages, and consequently asphyxia, the sufferers would have gone through all the stages of marasmus.

These considerations prove that our definition requires a broader basis than the one already given, and we have fixed on the following:

By Phthisis Laryngea is meant any chronic alteration of the larynx, which may give rise to consumption or death.

Galen is the first author who treats of chronic affection of the larynx: but none of the symptoms he indicates, in the two single cases he relates, can be really considered as belonging to Phthisis Laryngea.

Whatever may be the opinion of modern authors, it is certain that *Ætius* merely copied Galen. They both considered the diseases in question easily cured. *Ætius* says he cured a great many (non paucos hoc modo affectos curavimus).

Morgagni gives various accounts of chronic diseases of the larynx, and we are indebted to him for the earliest cases that positively belong to Phthisis Laryngea. Yet this author no where establishes the existence of Phthisis Laryngea as a special disease, which may end fatally, except by suffocation.

Borsieri is the first who positively asserts that the larynx and the trachea may become the seat of ulceration, which may engender hectic fever and death. His opinion in this respect is clearly expressed in the paragraph of his work, which we have chosen for an epigraph. (*Inst. Med. Prat.* tom. iv. p. 57.) But *Borsieri*, notwithstanding the opinion of his great ap-
 mirer, *Joseph Franck*, has described the Phthisis Laryngea more theoretically than

practically. Many of the symptoms which he indicates as characteristic of the disease are frequently wanting. *Franck* himself admits this to be the case, and there are also many very important symptoms of which he makes no mention.

Besides these authors, some French practitioners have written on the ulcerations of the larynx and trachea. The most remarkable are *Messieurs Double*, in 1806, *Cayol*, 1810, *Pravaz*, 1824, and, finally, *M. Louis*, who, in his work on Pulmonary Phthisis, has published the alterations of the larynx in tuberculous patients, which researches are extremely valuable, and merit entire dependence.

CHAPTER II.

ORGANIC ALTERATIONS.

In this chapter we shall treat not only of the alterations of the larynx, but also of those in the pharynx and trachea. Nevertheless we shall merely give our attention to diseases not immediately connected with the larynx, when it is necessary to elucidate some disputed points connected with the history of the Phthisis Laryngea.

We shall divide the diseases of the larynx in two great classes; 1st. Those that affect the mucous membrane. 2nd. Those that affect the cartilaginous rings beneath the mucous membrane.

Redness and Swelling.—The redness of the tissues after death is generally considered as a symptom of previous inflammation. This is undoubtedly the case, but, in our opinion, the fact of there being sometimes no traces of redness on the corpse, in the parts which, during life, were the seat of intense inflammation, has not been sufficiently noticed. The same observations are applicable to the swelling. Do we not, as soon as life is extinct, often see erysipelas and chemosis turn pale?

These observations often find their application in diseases of the larynx. We have seen patients victims to inflammation of the throat and larynx, and yet those parts that were the seat of marked inflammation and tumefaction, at a post mortem examination, were found livid. In these cases may we not naturally conclude that organs which could not be seen inflamed on the living body, though inflammation was suspected, might owe their paleness to the fluids that run beneath them.

But if redness and swelling sometimes entirely disappear after death, when they exist, their value is commensurately high. Sometimes the upper part of the larynx

is of a deep red, and so hard and tumefied, that it is similar to the neck of the uterus. In our own practice we have merely met with one instance of the kind.

The spotted redness so common on the inflamed tracheal membrane is seldom perceptible on the epiglottis and in the larynx. This probably depends on the lesser vascularity of the latter, whose mucous membrane is naturally dense and pale.

Ulcerations.—We shall divide the ulcerations of the mucous membrane of the air passages into erosions, and what are commonly called ulcerations. The first merely relate to the mucous membrane, the second to the cellular mucous, or even to the fibro cartilaginous tissue.

Erosions.—In erosions the mucous membrane appears as if worn out, the flat borders gradually unite with the healthful part, so that it is impossible sometimes to discover the line of separation. But if the part be placed in water, the surface of the erosions is covered with a villous coat, similar to that found in animals of the canine species, and which never exist in the mucous membrane of air passages in man, excepting where the epithelium has been destroyed.

Erosion does not appear to us to be the first degree of ulceration. It often happens that there are numerous and considerable erosions without ulcerations; and, again, there are frequent, deep ulcerations, in parts where no erosions are evident. In one of the patients, whose whole case we have related, and whose larynx and trachea were delineated after death, the correctness of this observation is easily ascertained; for the mucous membrane which covers the thyroid cartilage is converted into a multiplicity of ulcers, while on that which covers the thyroid cartilage there is no trace of erosion, and the trachea is covered with an innumerable quantity of erosions, but has no ulceration.

We have never observed erosions of the mucous membrane of the larynx and trachea excepting among individuals, who besides the affection of the larynx, were afflicted with pulmonary phthisis. Is this fact to be considered as a confirmation of Mr. Louis's opinion, who believed these erosions to be due to the action of expectoration? We must admit that we have not sufficient materials to decide this question; but we beg to state it appears more rational and satisfactory to attribute this lesion to a tuberculous diathesis, whose influence in the production of ulcers of the ilcum in phthisis must be undeniable.

Ulcerations.—We shall not describe ulcerations of which the form is generally known.

We have seen this species of affection invade the whole larynx, the vocal chords, the aryteno-epiglottic ligaments, and the mucous membrane which covers the epiglottis. Sometimes these ulcerations reach the cartilages, which they corrode and decay. In most cases the mucous membrane is alone destroyed, and seems evidently to be the cause of the disease; but it also frequently occurs that there are abscesses under mucus; the ulceration is then made as certain fistulous sores under the skin. We have given several cases of this sort of affection; among others one from Morgagni, Letter 15, Art. 15, and a second collected by Dr. Carmichael, and published in the Irish Transactions, 1820.

Alteration of the Cartilages. Ossification of the cartilages of the larynx, which is a normal phenomenon when the individual has arrived at a certain age, often arises if the vocal organ has long been the seat of chronic inflammation. But the cartilages need not be affected with caries, the slightest ulceration, the slightest chronic inflammation of the mucous membrane which surrounds them suffice.

Analogy may be very useful in explaining this phenomenon. Is not the periosteum of a bone often infiltrated with a species of bony matter, near a fistula of long standing? And when a young woman falls a victim to an ulcerated cancer of the breast, do not the perichondrium, and even the cartilages surrounding the ulcer, leave traces of ossification not existing on the opposite side?

The pathological mode of ossification of the cartilage of the larynx is not the same as that of the normal ossification of the fœtus. The whole breadth of some parts of the cartilage is ossified; from thence proceed two thin bony layers, between which the cartilaginous portion remains. If the part be then submitted to ebullition, the cartilage comes off the bone exactly like an epiphysis.

Several of these bony parts are generally found in the same cartilage, but complete ossification only takes place at an advanced period of life. The cricoid cartilage is most frequently ossified, then the thyroid. We have never found the arytenoid cartilages ossified.

Necrosis.—The necrosis of the cartilages of the larynx is far more frequent than most authors who have written on this subject generally suppose; it may be known by the following characters:—

1st. The necrosed part is constantly denuded, as, according to the laws of organization, the separation of the dead from the living parts must take place: the sequestrum may be then rejected by the mouth, of which we have given remarkable examples; or, what more frequently occurs, it is retained, and causes fatal disorders.

2nd. The necrosed part is always ossified; this character never fails when the disease is of long standing: and it is well known that, in dangerous fevers, necrosis of the cartilage of the larynx sometimes takes place without ossification.

The production of this phenomenon seems to originate in the following manner:—

The ulceration, which most frequently causes necrosis, begins by producing an inflammation of the perichondrium, and consequently, according to the law already established, a bony effusion in the subjacent cartilage, and when the ulceration has reached the bony cartilage, necrosis easily takes place, ossification having deprived it of a great portion of its vitality.

What renders this explanation more plausible, is the well known fact that, in young subjects, ossification is difficult, and that necrosis is not found, but caries. We must also remark that the arytenoid cartilages, which we have never seen ossified, have never been found necrosed.

Caries.—This alteration has appeared to us less frequent than necrosis. It is always the result of an ulceration commencing on the mucous membrane, and has destroyed in a few months, sometimes in a few weeks, the cellular tissue, which separated it from the cartilage. Caries can completely destroy the epiglottis, of which Joseph Franck, and M. Louis have related several cases. It can even perforate the thyroid cartilage, of which we have given two examples, and even leave no traces of arytenoid cartilages.

We have never met with patients subject to caries, unless previously attacked with tuberculous pulmonary phthisis: it is not so with necrosis. This is a characteristic which places a striking line of demarcation between these two species of alterations.

The pathological lesions, of which we have given a rapid sketch, create in all the adjoining parts disorders more or less remarkable. The most serious and the most frequent is undoubtedly the tumefaction of the mucous membrane,

which is followed by the occlusion of the respiratory tube. In our opinion it was useless to make a special disease of that sort of swelling, called œdema of the glottis. Further on we shall give an exposition of our own views on this subject.

Foreign bodies existing in the larynx.

—Foreign bodies, of different nature, are often sometimes found in the larynx; they may have been formed in the organ itself, or introduced into it.

Foreign bodies formed in the larynx.—

Lieutaud, Bonnet, Mogagni, Desault, Pelletan, &c., have given to science very curious facts of this nature. Polypusses, vegetations, cancerous tumours, hydatids, false membranes, more or less extended, have been found in the larynx. There are examples of stones found in the cavity of the larynx, and thus preserved a long while. It is easy to foretell the accidents that may be occasioned by these morbid productions, not only on the local pain they cause, but they also prevent free respiration.

Introduction of foreign bodies into the larynx.—We have nothing new to relate respecting the accidental introduction of foreign bodies into the larynx. The multiplicity of cases of this kind render any comment of ours unnecessary, and could only tire our readers.

Should Phthisis Laryngea be separated from Tracheal Phthisis.—We have replied negatively to this question for the following reasons:—

1st. These two lesions have the same origin and the same causes.

2nd. They are frequently simultaneous in the same subject.

3rd. The accidents they give rise to are of the same nature.

4th. The treatment is nearly similar.

CHAPTER III.

CAUSES.

Phthisis Laryngea is not a special disease, but may be caused by various lesions of different nature. Owing to the organ they attack, and the functional symptom they produce, the well-known denomination of Phthisis Laryngea has been applied.

It is therefore next to impossible to study the causes which may give rise to it; for it would be necessary to review the whole of Nosology.

We have, in fact, seen Phthisis Laryngea produced by screaming, by forcing the voice too much, immoderate coitus, masturbation, exterior violence, cancer,

tumours of different nature developed on the larynx, and we have given examples of all these different cases.

Besides these different causes, sex and age have great influence on the development of the Phthisis Laryngea.

Age.—Nearly all the individuals mentioned by ourselves, and other authors, were at least 20, none above 50: the principal number were between 30 and 46.

Sex.—According to Mr. Jones and M. Louis's observations, it follows that among tuberculous individuals the alterations of the trachea and larynx are twice as frequent among men as among women.

The observations respecting sex or age are well reconciled; women are much less subjected to alteration of the vocal organs than men; and children, whose constitutions have great analogy with women's, seem to share the same immunity.

CHAPTER IV.

We have divided Phthisis Laryngea into four kinds:

1st. Simple, viz. that produced by the common causes of general phlegmasia.

We acknowledge the first kind not only from our own observations, but from those of the most noted men, among whom are M.M. Double, Portal, Louis, and Andral.

2nd. Syphilitic. That due to venereal ulcers, either primitive or consecutive, and whether they, in the first instance, attack the larynx, or are propagated from the pharynx.

3rd. Cancerous. That which depends on the development of a cancerous tumour in the larynx.

4th. Tuberculous. That which shows itself after the existence of pulmonary tubercles have been proved.

We have seen a case of Phthisis Laryngea partaking of the nature of herpes, but we do not think a single case will suffice to establish a fifth species.

(To be continued.)

EPEDEMIC FEVER

OF THE WEST INDIES.

(Continued from p. 972.)

The whole case is given in an Appendix to the Report, and which was transmitted to the Director General of the Army Medical Department by the present Deputy Inspector Griffin. I mention these facts to show that long practical experience places in our hands medi-

cines well calculated to facilitate the favourable termination of this malady, even in its worst forms; and I have brought forward an old, known, and efficacious practice, namely, that of mercurial fumigation, so that even in apparently desperate cases, the patient may have a fair chance of being saved by a little exertion of the experienced medical practitioner, although I look to the measures I have previously detailed as the grounds in the early part of the contest. The mercurial fumigation is performed with a preparation of calomel and sulphur, or it may be simply done by placing a drachm of pilula hydrarg. on a piece of tile put over some embers in an earthen cup; the cup is to be kept on the ground just between the patient's legs, he himself being enveloped in a blanket. It may be useful here to remark, that when I prescribe calomel in the fevers of the Antilles, and few practitioners have been more successful with this valuable remedy in the appropriate fevers, where indeed it is our sheet anchor, I have always despised the cry made by certain physicians against large doses of calomel, knowing how soon disorganization takes place in the West Indies; if Sydenham in his day could order twenty grain doses in England, the Colonial medical attendant in 1836 will soon learn that the dose to ensure success must be increased in these islands, where the intestinal tube frequently resists the strongest medicine in exciting its daily functions, and by that finally restoring the biliary apparatus to energetic and healthy action. Small doses of calomel ought therefore to be avoided. Where such doses have been thought to answer, it is probable that the cases would equally have recovered without a single grain of calomel. I am proud to bear testimony to the usefulness of this distinguished medicine, for I am very far from being a non-mercurialist, except at the beginning of the aggravated Asthenic remittent fever, which is the immediate subject of these pages.

Patients labouring under this variety of the fever should be seen every two or three hours during the first and second day, otherwise much good cannot be anticipated, nor can the remedies be given judiciously. Narcotics are remedies from which considerable advantages may be derived; when the bowels are inclined to costiveness, I give ten grains of Extract. Hyosycam. in half an ounce of the Liq. Annon. Acet. flavoured with syrup of

orange, or if the bowels are in a pretty soluble state, or where there are cerebral symptoms, the *Liquor Morphine Acetatis* will be preferable; yet, in cases where there is watchfulness, great prostration of strength, with a low and irregular pulse, the countenance being pallid, I find small doses of *Laudanum*, in a few spoonfuls of *Negus*, frequently repeated, to be as effectual in morbid derangements, and exciting the system into healthy action, as any other medicine we possess; I mean after a powerful impression has been made on the disease by the means I have already proposed. Still, if we prescribe narcotics, so as to induce refreshing repose, they ought to be given not sooner than eleven o'clock at night, a time when the fever is observed to be somewhat on the decline, at any rate, the skin is generally at this period moister. To assist the purgative medicines, taken at the onset, *Enemata* will be often required; that made of oil of turpentine, with castor oil, I believe to be the best for our purpose; turpentine having a particular property of subduing irritation in the intestinal canal, inducing therein the ordinary salutary action. If there should be pain at the lower part of the abdomen, which is a frequent symptom about the beginning of the third day, sixteen ounces of the *Enema Nutritivum* made of *Tous le Mois* and warm water, thrown into the rectum every third or fourth hour, as warm as the patient can comfortably bear it, will remove this unpleasant feeling. In two patients an injection of brandy and warm water was used, with marked and immediate benefit. Where there is a visible dryness and constriction of the skin over the body, especially about the umbilical region, and which had not yielded to the baths, heated oil of turpentine was applied to the surface, in way of rubefacient, with good consequences.

I administered the strychnine and Hydrocyanic acid in this epidemic, as well as in the Trinidad Cocorite fever, having observed that in both fevers the stomach seemed to be that particular organ of the Ganglionic system, which, in the progress of the disease, showed evident signs of derangement; so that the strychnine and Hydrocyanic acid, timely and judiciously given, preserved that important organ from morbid action, ensuring the due balance of the nervous system, if I may so express myself. In such instances no fatal black vomiting took place.

My reason, likewise, of persevering in

the *ptisana camphorata*, in which I increased, according to circumstances, the spirit of nitric ether, was the knowledge I had of the great sympathy existing between the brain and the urinary organs, and where there is lessened secretion of urine, the head is generally affected, but which is invariably relieved on the restoration of the secretion, therefore I ordered the *ptisana camphorata*, in conjunction with my other measures.

In some places the atmosphere had an epidemical character, the fever running, in such places, nearly through the whole of a family; the force and form of the fever depending, however, in a great measure, upon the previous good or ill health of the person attacked. One thing was quite certain, that whenever a family was so affected, a remove, to the distance of only two fields from the locality of the attack, caused an almost immediate disappearance of the fever. This favourable result was not surprising to me, having, during my long period of service in the army, invariably observed that regiments assailed with malignant remittent fever, have experienced similar benefit on a removal from barracks to tents, scarcely two hundred yards distant from each other. The fever has, I understand, been rather formidable in its assaults among the military quartered in this island. Report giving no less than ninety-five deaths in His Majesty's 14th Regiment,* as I think, from the well-known experience of the medical officers, that if such a mortality had taken place, the establishment of open encampments would have been resorted to. I intended to have given several detailed cases of this fever, but time will not permit, as the merchant vessel which takes this communication is to sail for England in a day or so; and this circumstance has made the present report shorter and more hurried than it otherwise would have been.

J. B. WATERSON,
Late Surgeon to H. M. Forces and to the
19th Regiment.

P. S. I have had no case of dissection, and I ought to state that my practice was most successful.

* Since writing the above, I am assured from the best authority, that the number of deaths is correct, as will appear in the returns sent home to the War Office.

ANALYSIS OF A BILIARY CALCULUS.

By M. DE KONINCK.

Read before the Royal Academy of Sciences of Brussels, on the 6th of August, 1836.

This Calculus was remarkable, not only for its size, but also for the manner in which it was expelled from the body of the individual in whom it formed. It seems to have originated in the bile of a person for nine years labouring under abscess in the right hypochondrium, occasioned probably by its presence; for since the calculus came away by the natural passage, he has completely recovered, and the sore cicatrized.

The calculus has an ovoid form, somewhat elongated, flattened towards the base. Its surface is remarkable for certain depressions, produced, most likely, by the resistance of the envelope which retained it. It does not offer those smooth facets commonly observable on biliary calculi, generally the result of their mutual friction. This circumstance leads to the inference that here the calculus was solitary. The colour of it is a yellowish-olive, slightly white towards the base; that of the depressions more deep; the odour is agreeable, resembling that of ambergrease. In specific gravity it is less than water: sawn across the middle it did not exhibit any nucleus which might have given it birth. From the centre to the circumference there proceeded radii, formed by minute crystalline laminae, transparent, of a faint yellow tinge. The crystalline nucleus was enclosed in a crust of the same substance, not crystalline, but more compact; its aspect was whiter. This crust which had only from 1 to $1\frac{1}{2}$ millimètre* in thickness, in nearly all its extent, was from 2 to $2\frac{1}{2}$ millimètres thick near the apex, and there existed in that situation a small cavity between it and the crystalline nucleus. This cavity was filled with the yellow colouring matter of the bile. The greatest diameter of the calculus is $21\frac{1}{2}$ millimètres; its height 43 millimètres; its weight 160.5 grains; its chemical composition as follows:—

Cholesterine	-	-	-	94.95
Yellow-colouring matter of the bile	-	-	-	1.41
Carbonate of lime	-	-	-	1.00
Picromel	-	-	-	2.43
Volatile oil and loss	-	-	-	0.21

100.00

* A millimetre is 1-25th of an inch.

As this composition corresponds with what the greater number of chemists have found to be that of biliary calculi, removed after death, it may be fairly presumed to have had the same origin.—*Bulletins de l'Académie Royale des Sciences, Bruxelles.* 1836. p. 279.

SIR HENRY HALFORD'S FORTUNATE ESCAPE.

We congratulate the profession that the life of this truly eminent and enlightened physician has been saved, after the late serious accident to which he was exposed. Most providentially, when the carriage broke down, his person was rescued; and, except some slight contusion and shock, he has not suffered. Had the College been deprived of his distinguished services, there is no man living who could have graced the President's chair like Sir Henry. We rejoice to add, that though he has entered upon his 71st year, his mind remains vigorous, and possesses the activity and acuteness of youth.

MEDICAL MEETING, AT CORK.

At a numerous and respectable meeting of the Medical Profession, held at Lloyd's Hotel, on the 24th ult.

John Woodroffe, Esq., M.D., in the chair.

The following Resolutions, as prepared in Committee were unanimously adopted:—

1st. That we regard with serious apprehension, the contemplated measure of placing the Medical Charitable Institutions of Ireland under the control of the English Poor Law Commissioners; because we conceive the present system of relieving the sick paupers in England to have totally failed in its object, and to be altogether inapplicable to the circumstances of this country.

2nd. That if the Bill for the introduction of Poor Law into Ireland, which has been read a first time in parliament, be carried into operation, confining legal relief to the workhouses, and leaving the support of the medical institutions for the sick poor dependant on voluntary contributions; that the existing medical charities must be extinguished for want of necessary funds, and the poor be thus deprived of medical attendance.

3rd. That the deputation at present in London, Doctor Nugent of Cork, and Surgeon Phelan of Clonmel, have fully

justified the trust and confidence reposed in them by the profession, and that we pledge ourselves to use every exertion to enable them to persevere in their arduous and useful exertions of obtaining for the sick poor of Ireland the inestimable advantages of a well regulated system of medical relief.

4th. That Dr. Johnson, the editor of the *Medico Chirurgical Review*, and Dr. Ryan, the editor of the *London Medical and Surgical Journal*, are entitled to the warmest thanks of this meeting, for their very kind reception of, and effectual aid afforded to the deputation, and that our Secretary be requested to convey the resolutions to these gentlemen.

5th. That the best expression of our thanks be also conveyed, on the part of the medical profession of the province of Munster, to the British Medical Association, for the sympathy and good feeling they have evinced, and the co-operation they have offered, for promoting the objects of the deputation.

Dr. Woodroffe having vacated the chair, and Dr. Callanan having been called thereto, it was

Resolved—That the best thanks of the meeting be accorded to Dr. Woodroffe, for his dignified and proper conduct in the chair.

A. H. CALLANAN, M.D., Chairman.

RICHARD CORBETT, M.D. }
JULIUS B. EVANS, M.D. } Secretaries.

SENTENCE ON MR. PENRUDDUCK.—The Apothecaries' Company are accused by Mr. Phillips of having induced Mr. Penrudduck to plead guilty to an aggravated assault, and then declined to appeal to the Judge in mitigation of punishment. The sentence of the Court was, twelve months imprisonment, and to give bail in the sum of 200*l.*, and two sureties in the sum of 10*l.* each.

Such is the humanity of the Rhabarbarians, even in a case where the health of a fellow citizen is endangered, and where it would have been much more noble to interpose, than to punish with great severity an individual whose excited feelings led him to violate the law.

POOR LAWS.—The Board of Guardians of the Eastbourne Union, on advertising for medical tenders for the ensuing year, have not received one from the medical attendants of the last year; and when it shall be publicly known what the offer to

medical gentlemen, according to the orders of the Commissioners, is, it must appear wonderful that any person of liberal education should have condescended to receive them. The advertising is only a blind, as the Guardians have no power to accept a tender above the following amount. For medical attendance on each division of the Union, *four pence* per head on the pauper population of the district!—which did not yield one shilling a year, at which rate the late medical attendants were great losers.—*Brighton Gazette*.

At a meeting of the medical profession of Cheltenham and its neighbourhood, on Wednesday, to take into consideration the effects of the new Poor Laws upon that body, the following resolution was unanimously adopted: "That the system adopted by the Poor Law Commissioners, in providing medical relief for the poor, is degrading to the medical profession, inefficient as regards the sick paupers themselves, and productive of effects equally as pernicious to the community at large."—*Cheltenham Chronicle*.

A meeting of the surgeons residing in Mansfield, Alfreton, and Ollerton, was held on Monday, at the Swan Hotel, Mansfield, when an address to the Legislature was determined upon, recommending in express terms the substitution of some other mode of electing surgeons to the charge of the sick poor less derogatory and insulting to the profession at large than the one now in use.—*Derby Mercury*.

CHLORINE GAS.—Dr. Deblois, of Tour-nay, employed an injection of chlorine gas, with the view of effecting a radical cure in hydrocele. The process is thus described: the chlorine gas is contained in a bladder having a pipe and stop-cock affixed, which can be readily fitted into the canula of the trocar, when the fluid of the hydrocele has been drawn off; the stop-cock is then turned, and by pressing the sides of the bladder, the gas will be forced into the tunica vaginalis. When this sac was fully distended, M. Deblois removed the pipe and bladder, and covered the open end of the tube with the thumb, retaining the gas in the cavity for two minutes. It was then allowed to escape, and the injection repeated two or three times, by which means a cure was effected. The advantages are, the simplicity of the apparatus, and the equal distension of the whole sac.—*Bulletin Medical Belge*.

DISTILLED WATER OF THE ACACIA FLOWERS.—A water has been obtained from the flowers of the Acacia by distillation, by Messrs. Chevallier and Favrot, which is said to possess the property of exciting nausea and vomiting. Its medicinal powers are undergoing investigation by M. Bricheteau. It is recommended in the *Pharmacopœia Helvetica*, as useful in cases of debility, obstruction of the bronchi by mucus, catarrhal hoarseness, and cough. Messrs. Chevallier and Favrot prepared it in the first instance, according to the directions of the Swiss *Pharmacopœia* by pouring three pounds of water on a pound and a half of the flowers, macerating for twelve hours, and then distilling on an open fire, until a pound and a half of the water had gone over. The product was very analagous to that of the *lactuca virosa*—its taste was slightly acid. Conceiving that this might depend on the mode of distillation, an equal quantity of the flowers was placed in a metallic cloth, and introduced into an alembic, containing three pounds of water, so as to be suspended over it, and not immersed in it. As the distillation proceeded, the steam arose, and passed through the flowers. The product had less of the virose odour than the preceding. The dose is from one to two ounces sweetened.—*Journal de Chemie Medicale et de Toxicologie*.

TINCTURA COPAIBÆ.—From a series of experiments made on the balsam of copaiba, it appears that a preparation in which calcined magnesia is triturated with the balsam, and the mixture after digested with proof spirit, will prove the best mode of administering this nauseous drug in the treatment of the various diseases for the removal of which it is applicable, both as regards the concealing its unpleasant taste and its action on the system. It is made by rubbing up twelve ounces of copaiba with six of calcined magnesia, allowing the mass to stand for a day, and then digesting it in a pint of proof spirit. When the balsam is dissolved, filter, and add half an ounce of nitric spirit of ether. Of this the dose will be ʒj to ʒiij two or three times a day. The liquid is at first transparent and colourless, but in the course of time assumes an amber tint; it possesses an ethereal smell, its taste is balsamic, with a slight copaibal after taste.—*Medical Botanical Society*. M. Faure of Bordeaux, in an article published in the *Journal de Medicine Pratique* for 1830, was the first to draw the attention of the medical profession to the combination of copaiba with magnesia.

LITERARY INTELLIGENCE.

The success of some new journals, has stimulated some enterprising individuals to bring out another periodical, to be called the *Medical and Physical Pickwick*, published by Churchill. *Boz!*

TO CORRESPONDENTS.

QUACKERY DINNER.—The price of the dinner ticket is a guinea, but we cannot inform our correspondent whether wine is included. The particulars may be learned from any of the Stewards.

T.—Our Dublin Correspondent has forgotten his promise. He is not aware that a former article produced effects which we did not anticipate.

A STUDENT OF ST. THOMAS'S.—The prosecution ought never to have been instituted; it will do the Medical Staff of the Hospital much more harm than good, and is in strict accordance with their antiquated, and still cherished, folly.

A STUDENT OF THE NORTH LONDON HOSPITAL.—Our Correspondent writes on a subject with which he is unacquainted.

A GOVERNOR OF ST. BARTHOLOMEW'S HOSPITAL.—The writer of the letter thus signed is in too great a passion; but we shall have much pleasure in publishing his letter, with our remarks, if he will favour us with his name and address, confidentially.

FREEDOM.—A Weekly Medical Journal is a medical newspaper, and ought to contain an account of passing events. It differs, however, from the public press in one respect, in containing a large proportion of scientific and practical matter, appertaining to a certain profession. If our contemporaries do not supply so much intelligence as we do, it is their affair and not ours.

ONSOR.—The author is a qualified quack.

B. L.—The report of the intended migration of the Surgeon-General for Ireland to this metropolis is as unfounded as that circulated some months ago, that Mr. Wallace was coming to settle in London under the patronage of the hon. member for Finsbury.

SCRUTATOR.—The account of the Liverpool ballot, though correct in all its statements, is too personal in its present form for insertion in our pages. In all the Medical Societies of London, the usage is, at annual election of officers, that the ballot-box should be examined by three scrutators, proposed by the President, after the conclusion of the voting, in order to avoid mistakes.

NOTES OF LECTURES ON PHYSIOLOGY.

BY DR. FLETCHER.

*Delivered in the Argyle Square School of
Medicine, Edinburgh.*

No. XVIII.

SENSATION.

Animal Magnetism—Experiments of the French Commissioners—The Commissioners Magnetized—No Effect produced—Conclusions at which they arrived—Effects of Imagination—Production of Crises and Convulsions—Effect of Manipulations—Imagination does Everything, and Magnetism nothing—Non-existence of the Magnetic Fluid—Experiments by M. Sigault—Effects proportioned to the Faith and Sensibility of the Patient—Cure of an Artist by Mummery—Cajoling a Patient—Effect produced on an Aching Tooth by the sight of the Dentist—Experiments in a Convent—Magnetizing a Nun—Ceremony of the First Communion—Rapid Spread of Convulsions among the Young Ladies—Cases of Alleged Effects independent of Imagination—Uneasiness and Agitation produced by a concealed Iron Rod—Convulsions produced during Sleep, by Motions before the Face—Experiments with a Patient in a Crisis—A Finger felt at Six Inches distance—Convulsive Twitchings produced by it—Startings produced by Motions at a Distance—Effects of Pressure on the Epigastric Region—Attempts of incredulous Practitioners—Jussieu, on the Medical Application of Animal Magnetism—Effect on Suppressed Perspiration—Case of a Female Servant—Effect of Magnetism on Opacity of the Cornea—Cure of Ague by Animal Magnetism—No Effect on Phthisis Pulmonalis—Little Influence on Scrofulous Tumours—Alleviation of Dropsical Symptoms—No Influence on

No. 2.

Ascites—Little Diminution of Abdominal Enlargement—Better Success in Recent Paralysis—Case of a Washerwoman—M. Deslon's Practice in Vomiting of Blood—Connection between Magnetism and Electricity—Dr. Vazer's Experiments—The Magnetic Fluid bottled up—Effect of Imitation—Cold produced by a Warm Hand.—Cold and Heat produced by Magnetism—Explanation of its alleged Odour—Effects of Magnetism on Asthma, Tumours, Scrofula, Cholera, and Hernia.

The commissioners instituted a great variety of experiments, varied in every possible form; and with the view of putting it to a personal test, they submitted to be magnetized themselves. No effect, however, was produced. The conclusion to which they arrived, after all their investigations, were the following: "1. Imagination is sufficient to produce all the effects attributed to magnetism. 2. Magnetism produces nothing independently of the imagination. 3. Imagination is the agent which produces the crises. 4. Imagination acts equally in putting an end to the crises. 5. Imagination does everything, and magnetism nothing. 6. Imagination produces greater effects in public than in private; because the impressions and movements are communicated from one to the other. 7. The manipulations which the patients undergo serve to excite the imagination; and the effects spread by imitation. 8. This excitement of the imagination is hurtful, when it produces violent and convulsive effects. 9. These convulsions may become habitual, and spread through the country. 10. The magnetic fluid does not exist at all; and the means which are employed to put it in action are dangerous."

M. Sigault, the inventor of the operation called *Symphiseotomy*, gives some striking proofs of the effects of imagina-

D

tion ; as will be seen by a letter, from which I translate the following extracts. " Being on a visit at Marais, I allowed it to be thought I was an adept in animal magnetism ; and produced various effects on a lady there. The tone of my voice, the serious air which I put on, together with my gestures, made a great impression, which she endeavoured at first to conceal ; but having placed my hand on the region of the heart, I perceived that it palpitated. Her state of oppression was further indicated by constriction of the chest. To these symptoms others were soon added. The face became convulsed ; the eyes rolled ; she became faint ; vomited her dinner ; had several evacuations from the bowels ; and fell into a state of extreme weakness. I repeated the same process with several other persons ; and with more or less success, according to their degree of faith or sensibility.

" A celebrated artist complained, for several days, of a nervous pain in the head. Having persuaded him that I had been initiated into the mysteries of M. Mesmer, I removed his pain very quickly, to his great surprise, by means of a few gestures.

" I produced the same effects on a young man, likewise attacked by pain in the head ; but as he felt nothing from the gestures I first made, I placed my hand over the false ribs, desiring him to look at me. He was immediately seized with general uneasiness, yawning, oppression at the chest, and palpitations. From that moment he did not doubt the power I had over him. Applying my finger to the part affected, I asked him what he felt. He replied, that the pain was getting lower. I told him I was going to conduct it into the arm, and make it come away through the thumb, which I squeezed tightly. He believed what I said, and was free from pain for two hours ; at which period he stopped me in the street, and told me his malady had returned. The effect appears to me to be analogous to that which is produced by the mere sight of the dentist on those who come to have a tooth extracted.

" Lastly, being in the parlour of a convent in *Fauberg Saint Germain*, a young lady said to me, ' You go to M. Mesmer then ? ' I replied, ' Yes ; and I can magnetize you through the grating ! ' At the same time I presented my finger towards her. She was alarmed ; felt uneasy ; and begged me to desist. She was so strongly affected, that had I persisted, she would

certainly have been seized with convulsions."

A striking instance of the rapidity with which convulsions, when once manifested, spread among the spectators, is found in the following fact which occurred at the church of St. Roch, at Paris, in 1780. " On the day in which was performed the ceremony of the *First Communion*, after the evening service, the customary procession took place as usual out of doors. Scarcely had they re-entered the church and returned to their places, when a young girl was seized with convulsions, which spread with such rapidity, that in half an hour, fifty or sixty girls (from twelve to nineteen years of age) were affected with them. A few cases occurred during the week ; but on the Sunday following, being assembled at school, twelve were seized with similar convulsions ; and no doubt more would have been affected, had not all the scholars been immediately sent home to their parents. They were obliged to increase the number of schools ; and by thus separating the young persons, and having only a small number together in one place, three weeks were sufficient to dissipate entirely these epidemic convulsions."

One of the commissioners did not agree in the report of his brethren ; and gives the following among other instances, of effects produced independently of the imagination. " Placed on one side of the trough, opposite to a female patient whose blindness, occasioned by two very thick cataracts, had been ascertained (a month previously) by the commissioners, I saw her remain quite tranquil for a quarter of an hour ; appearing to be more occupied with the iron branch directed towards her eyes, than by the conversation of the other patients. At a time when the noise of the surrounding voices was sufficient to distract her hearing, I pointed an iron rod towards her stomach, at the distance of *six feet*. In three minutes she became uneasy and agitated, and turned round in her chair, feeling assured that somebody, placed behind or at her side, was magnetizing her. Her restlessness ceased almost immediately on discontinuing my manoeuvre. A quarter of an hour afterwards, I tried the same plan, with the same result. I was assured that the patient had received no further benefit from her treatment, than that of being able to see confusedly objects placed at a distance of *three or four inches*, and, besides, the dusk of the evening had come on." In order to ren-

der this case satisfactory, we ought to have a more accurate account of the state of the patient's vision.

The following anecdotes are to the same effect. "A patient whom magnetism put into a profound sleep, for a longer or shorter time, exhibited at intervals (without waking) a fugitive convulsive starting, particularly excited by any unusual noise in the room; such as the clanking of two pieces of iron, or the cry of some patient in a *crisis*. I succeeded in producing a similar convulsion, by means of movements performed at a little distance from his face. I tried the experiment several times, and almost always with success; observing, at the same time, that no strange noise unconnected with magnetism, produced the same effect." The state of this patient was probably that of magnetic *somnambulism*, in which persons are susceptible of many impressions to which they are insensible when awake.

"The *crisis* of another patient consisted of a general spasmodic affection; accompanied with temporary loss of the senses, without any violent motion. The head was thrust forward; the eyes were closed; the arms carried backwards, and stretched out at full length; the hands open; and the fingers widely separated. On applying my finger to her forehead, between the eyes, it appeared to give her some relief. If I drew it away gently, her hand (although not in contact with it) followed it mechanically in all directions. If, after having thus drawn her hand to the *right* side, I presented my other hand within an inch of her *left* hand, she drew it away precipitately. These movements were repeated three or four times within ten minutes; after which the spasm diminished, and the sensibility was no longer so great. I tried the experiment only once; because I had seen the same phenomena produced by another physician, a month previously. When the spasm was over, the patient did not know what had passed." The last-mentioned fact (ignorance of what had occurred) confirms the opinion that the state of this patient also was near akin to that of *somnambulism*.

"The slight magnetic motions made so great an impression on another patient that when I passed the finger along the back, at the distance of six inches, without her being previously aware of it, she was suddenly attacked by convulsive movements and repeated startings, which announced to her the action which was

going on, and lasted as long as the action itself.

"The rooms contained several other patients, of both sexes, and of more or less irritable constitutions, who likewise felt, though less vividly, the effects which I have just related; especially when excited by pressure over the region of the stomach. If a finger was moved about unawares to them, over the head, or along the back, without touching the parts, or even at some distance, they often started briskly, and turned round to see what was practising upon them. This involuntary and unexpected motion was excited especially by medical men, who had but recently commenced their attendance, who, before executing openly the ordinary manifestations, stayed out of the circle of patients; testing covertly, and with distrust, the properties of an agent newly revealed to them. Emboldened by success, they afterwards entered into a more extended trial of its powers. I produced this effect very frequently when I first attended; but, suspecting either that the patient was aware of my intention, or that the motion would take place without me, I remained a long time behind two patients, waiting for favourable opportunities of making the trial. It almost always succeeded; and when I did not act, no starting took place. I have sometimes seen the same effects produced by other magnetizers upon patients whose attention I engaged in an opposite direction."

With respect to the medical application of animal magnetism, M. de Jussieu gives the following instances of its curative effects: "Suppressed perspiration may be restored by magnetic contact. I met with a proof of this in the country, in the case of a female servant; who, in consequence of interrupted perspiration, suffered for two days with severe pain along the thigh. This woman knew nothing of animal magnetism, with which I was then very little acquainted myself. I thought it, however, a very fair opportunity for making trial of its virtues. While I was listening to the prolonged recital of her complaint, I applied one finger to the stomach, and another to the painful part. Heat returned immediately, and was followed by a general moisture, which made the pain disappear almost entirely. The patient, surprised at the effect, was able to walk at the end of half an hour, with the assistance of a stick, although previously she had not been able to stir. Two hours afterwards the move-

ment of the finger from head to foot over the bed-cover, was sufficient to excite an abundant perspiration, which lasted all night. She was completely cured in two days, by this treatment alone.

"Among the patients submitted, with some degree of success, to the magnetic treatment, several might be mentioned with affections of the eyes. Two opacities which covered the eyes of a female for five years, were so thick that the iris could not be seen. No sensible effect was produced by the magnetic treatment for three weeks; but, at the end of that time, she became subject all at once to very frequent *crises*. They commenced with a fit of convulsive and involuntary laughter; to which succeeded a rigor, and a faintness, of short duration. Simple contact in the region of the stomach, or even an approach to that part, was sufficient to excite the convulsion. If the finger or the iron rod was directed towards her at a still greater distance, a feeling of uneasiness only was produced. The spots began to become thinner, and the iris to be seen; and the patient could distinguish colours and subjects placed at three inches distance.

"The magnetic treatment has cured several quartan agues; or, at any rate, they have ceased without the employment of any other remedy. It has procured abundant expectoration in *humid* asthma; and sometimes has prevented the paroxysm in *dry* asthma. In phthisis pulmonalis, it has always appeared more hurtful than advantageous. Its action upon scrofulous humours was scarcely perceptible. It *relieved* a dropsical female, by procuring some evacuations, but did not *cure* her. Enlargement of the abdomen in another patient varied very much, and at the end of three months, there was not much diminution. Encysted dropsy, in a third, obstinately resisted all the methods employed; and paracentesis, which had become necessary, gave issue to fourteen pints of water. In spite of the continuance of animal magnetism, the swelling reappeared in a month. It gave better hopes in some cases of palsy of the extremities not of long standing; but I cannot give my attestation to any complete cure.

"The effort made by a washerwoman in lifting a tub excited a severe pain in the arm, and especially the wrist. The application of a poultice transferred the pain to the shoulder, which became swollen without redness. She could not move her elbow; and the motion of the

fingers, and especially of the hand, was a little obstructed. The shoulder was so full of pain that it could not bear the slightest touch. The weight of the clothes hurt it. The patient had tried various remedies during a whole twelve-month without success. She could not sleep. She then submitted to magnetic treatment; and, from the first days of its employment, the pains became less severe, and she obtained some sleep. The finger drawn along the arm, or fixed over the shoulder, produced an abundant perspiration in those parts. The pain diminished much, and changed its place repeatedly. It sometimes returned when the weather changed; but again disappeared. Motion returned insensibly. The patient regained the power of using the different articulations, one by one, and of carrying her hand to the head. Such is the state of the case when I last saw it.

"A man subject to violent fits of coughing, which often terminated by vomiting of blood and mucus, had a very long paroxysm, which was interrupted before its conclusion by an accident, which brought back the convulsive efforts which had ceased, and suppressed all expectoration. The eight following days passed with uneasiness and anxiety, were unavailingly employed in endeavouring to procure the return of the crisis. They produced only convulsions, and increased the feeling of oppression. At the end of that time, he was touched in my presence by M. Deslon, who, in half an hour, brought on a cough without convulsions, accompanied by abundant vomiting, and followed by an evacuation of the bowels, and the appearance of better health."

With respect to the connection between animal magnetism and electricity, Dr. Vuger remarks, "I have observed that the magnetic matter is almost always identical with the electric fluid; and that it is propagated like the latter, through intermediate bodies. Steel is not the only body which is capable of becoming magnetic; for I have imparted magnetism to paper, bread, milk, leather, silk, stones, glass, water, different metals, wood, men, dogs, and in fact to every thing I touched. I have filled flasks with magnetic matter, in the same way as is practised with the electric fluid."

The effect of imitation is seen in the following case. "A lady of my acquaintance," says Dr. Bertrand, "who by magnetism had thrown a great number of patients into a state of somnambulism,

made them feel a sensation of coldness, even when she held her *warmed* hand at some distance from their bodies. The *first patient* magnetised by this lady, had experienced a feeling of coldness, and had declared that the magnetic fluid was cold, and nothing else was necessary to make all the other patients likewise feel an impression of coldness from the magnetic fluid, sometimes amounting to freezing." As to the alleged odour of the fluid, it was found to be owing to cutaneous transpiration, together with the odour of the iron heated by the hand.

"A poor woman," says M. Bourdois de la Mothe, "was attacked by a well marked malignant fever. She steadily refused every remedy; demanding only that a vessel of water should be kept constantly by her side. She remained quietly all day on the straw, which served her as a bed; drinking water all day, and doing nothing else. The disease developed itself; passed successfully through its different stages; and terminated in a complete cure. Mademoiselle G. had two enlarged glands in her right breast, which gave her much uneasiness. Before commencing the use of remedies, M. Bouvart recommended amusement. A fortnight afterwards she was seized at the opera with a violent cough, and so abundant an expectoration, that she was obliged to return home; and, in the space of four hours, spat up about three pints of glairy fluid. An hour afterwards, M. Sallin examined the breast, and did not find in it any vestige of the enlarged glands." Had animal magnetism been resorted to in these cases, it would have obtained the credit of the cure.

The commissioners tried the effect of magnetism on seven poor persons; of whom four, whose maladies were asthma, swelling of the thigh, scrofula, and St. Vitus's dance, experienced no effects whatever. Of the rest, "A woman, named Charpentier, who had been thrown to the ground against a beam, two years previously, had remained in a bad state of health ever since. At one time she lost her sight; but partially recovered it. She stated herself to be the subject of double hernia; and the abdomen was so tender that she could not bear any pressure. This patient was magnetised like the others by the application of the fingers; the pressure of which gave great pain. On directing the finger towards the hernia, she complained of pain in the head; and the finger being placed before the face, she said it prevented her

breathing. On the finger being moved repeatedly from above downward, she had convulsive motions of the head and shoulders, as if from a surprise, mingled with terror, and resembling those produced by cold water thrown on the face. She appeared to be equally affected when her eyes were shut. Another patient experienced effects of the same character, but much less marked. The seventh patient, Francis Grenet, had diseased eyes; particularly the *right*, with which he could scarcely see, and from which there was a considerable discharge. When the *left* eye was magnetised, by putting the thumb near it, and moving it about before it, for a considerable time, he felt pain in the globe of the eye, with lachrymation. When the right eye, which was most diseased, was magnetized, he felt nothing."

Patients of a better class were likewise submitted to the action of magnetism. One gentleman who had a swelling in the knee, with pain in the region of the patella, "declared that he felt nothing, except when the finger was passed before the diseased knee, when he perceived a slight warmth in the habitual seat of the pain. Madame de V., labouring under a nervous affection, was several times on the point of falling asleep, while the magnetic process was going forward. This process was continued for above an hour, and chiefly by the application of the hands; but she only felt agitation and uneasiness."

CLINICAL LECTURE,

Delivered March 28, 1837,

AT THE

NORTH LONDON HOSPITAL,

By PROFESSOR COOPER.

Fractured Rib, with Emphysema.

Surgeons commonly understand by the term emphysema, a swelling arising from the passage of the air from the lungs, or other parts connected with respiration, into the cellular tissue, all the different portions of which are continuous, and communicate freely by their areolar structure. This is known even to persons out of the profession. Thus at the Bicêtre, the prisoners used to get into the infirmary by making a slight puncture on the inside of the cheek, and then discharging their mouths with air, so as to force it into the cellular tissue, and cause an enormous swelling of the face. Con-

scripts, to avoid service, play similar tricks, and often inflate the loose cellular tissue of the scrotum. But the word is sometimes employed in a more extensive sense. Thus, in mortification, there is frequently emphysema, arising from the decomposition of parts. There are also other cases, in which emphysema presents itself, unconnected with any wound of the lungs. During the space of two years and a half, that the North London Hospital has been opened for the reception of patients, numerous and diversified as the accidents brought to it have been, I believe only one instance of emphysema has fallen under our notice, and that was in a patient under my care in the early part of the present session.

James Collins, aged 40, admitted October 12. On the 11th he fell across a gas-pipe, and hurt his side. He went home, and as he was in a good deal of pain, some blood was taken from the arm by the practitioner who first visited him. He passed a restless night, being at intervals much distressed with difficulty of breathing, and pain in the side, over the seat of injury. He was brought to the hospital about two p. m. On examination, a crepitus was discovered below the left axilla, indicating fracture of one or more ribs. At the same time, it was manifest that injury of the lung had also occurred, for a considerable emphysematous swelling was apparent over the anterior surface of the chest and abdomen, down to Poupart's ligament. It occupied likewise the whole of the neck, face, and back, down to the crests of the ilia; extending at the same time down the left arm as low as the elbow, and down the right to the insertion of the deltoid. The patient complained of great difficulty of breathing, pain in the situation of the fracture, and of a troublesome cough.

Pulse 90, full and hard.

After he had been placed in bed, a broad bandage was applied round his chest, 3x more blood were taken from him, and 5 grs. of calomel and ʒj of jalap given.

13. Had passed a bad night, breathing with great difficulty, and suffering severe pricking pain whenever he coughed. The emphysema, however, had subsided considerably: an important and most favourable change, showing that the air did not continue to escape from the rent in the lungs so freely as at first. Bowels had been twice copiously acted upon.

Pulse 84, and rather full.

Saline mixture directed to be taken every third hour, with small doses of

sulphate of magnesia and tartarized antimony.

14. Has had another restless night, and been sick, probably from the medicine.

Emphysema still further reduced. No pain in the side, except when the patient coughs. Breathing easy—tongue moist—bowels open. Saline mixture discontinued.

18. Cough rather more troublesome, especially in the night.

Nov. 8. Leeches were applied for the relief of the pain in his side.

Nov. 19. Discharged well.

Emphysema, contemplated generally, may be distinguished into two kinds, according as it may be the consequence of a wound of some of the parts, composing, or directly connected with, the organs of respiration, or according as it may proceed from other causes, especially those of a pathological character. Although some of these latter received a degree of elucidation from the researches of Laennec, and other eminent pathologists in France, they are still but imperfectly comprehended. Thus we know that the lungs themselves are subject to a species of emphysema, unconnected with any external wound, and in certain inflammatory diseases of the digestive tube, gas is sometimes found under the mucous membrane. Nay, this latter may be burst by a blow on the abdomen, and the air escape into the subserous cellular tissue, and thence all over the body; for in ruminating animals, whose food ferments, and generates a prodigious quantity of gas,

the same mischief is more common than in man. One form of emphysema then, that which is most interesting to surgeons, is the *traumatic*, which has varieties, according as it originates as a complication of wounds, *apparent* or *concealed*, of the lungs, bronchi, trachea, larynx, or other passages or cavities to which the air has access in respiration; or according as the emphysema follows ruptures of these parts produced by the air itself.

Gentleman, doubtless you understand the mechanism of respiration. You know that, in inspiration, the lungs are nearly passive, following and keeping close to the parietes of the chest, as well as to the diaphragm. Then the capacity of the thorax is augmented in every direction, and thus the rush of air into the trachea, bronchi, and air-cells of the lungs is determined. No doubt you also know equally well that, in expiration, the lungs, being compressed on every side from the circumference towards the centre, yield to the power of the expiratory muscles, and the air, which has entered into them during inspiration, is now expelled again, somewhat changed, however, by the chemical influence of the respiration on it and the blood itself.

These alternations of expansion and contraction of the chest, accompanied by corresponding variations in the capacity of the lungs, constitute in these the mechanism of respiration.

Now, supposing the sharp end of a broken rib should happen to tear or deeply wound the texture of the lungs, while there is no external wound of the muscles and integuments, an emphysematous tumour will be particularly likely to follow. This must be very intelligible if you consider that, when the chest expands, the atmospheric air will not only be drawn into the wounded lung, but also through the breach, or laceration of this organ, into the serous cavity of the pleura. Then, on expiration taking place, the air in the sac of the pleura, not being capable of re-entering the wound in the surface of the lung, which organ is already full of air, and the same air being compressed by the action of the muscles of expiration, is forced through the breach in the pleura costalis into the cellular tissue of the parietes of the chest in the vicinity of the fracture. The quantity of air which is thus thrown into the cellular tissue, becomes greater and greater by a repetition of the same actions, and at length is diffused to a very great extent, sometimes

nearly over the whole body, and so as to inflate the subcutaneous cellular tissue to the thickness of six or seven inches.

But, gentlemen, the chief source of danger is not the external emphysema under the skin, but the accumulation of air, which sometimes takes place in the sac of the pleura, and even in the interlobular cellular tissue of the lungs themselves. Indeed, before the air escapes into the cellular tissue, it must first collect in the pleura. Hence, the vast oppression of breathing, the feeling of suffocation, and imperfect oxydation of the blood. However, when the common cellular tissue under the skin, and between the muscles, or in the sheaths of the vessels, and around important nerves, is enormously inflated, there can be no doubt that the pressure made by the air on the blood-vessels, nerves, trachea, &c. must in some degree contribute to aggravate the symptoms. Thus, by the pressure on veins, the return of blood must evidently be retarded, and the free passage of the air to and from the lungs more or less interrupted. The innervation and circulation generally must likewise be unfavourably interfered with. Emphysema may arise not only from an injury of the lung by a broken rib, or sternum, but from a wound occasioned by a penetrating weapon, or gunshot mischief. The risk of its occurrence will always be greater in proportion as the wound in the parietes of the chest, however produced, is narrow, and indirect, or tortuous. When more free and ample, the air enters and escapes from it in the movements of respiration, just in the same way as it passes into and out of the glottis, and at the same time, and from the same cause. I have seen many examples of emphysema from gunshot wounds, from stabs with narrow knives, and from broken ribs. Abroad I have known it follow the stab of the stiletto.

Wounds of the trachea, larynx, or bronchi, may also give rise to emphysema. Here the air *escapes directly* into the *cellular tissue*, without first getting into any intervening cavity like that of the sac of the pleura, then through the root of the lung and mediastinum into the general cellular tissue. The swelling in such cases first presents itself above its clavicles. The air escapes also only in expiration, whereas, as in wounds of the lungs, the air is first drawn out of them, and escapes into the sac of the pleura only in inspiration, whence it is afterwards expelled into the cellular tissue

on the contraction of the chest in expiration. Sometimes there is no external wound of the lungs, but the air cells and interlobular cellular texture are ruptured in violent fits of straining, coughing, &c. as in parturition, whooping cough, violent efforts to expel foreign bodies from the larynx in hysteria, and during the efforts to reduce dislocation of the shoulder, the air escapes into the interlobular cellular tissue, and, in this manner, occasion emphysema, either with or without pneumo-thorax being first produced. Thus it becomes a complication of ulceration of the lung, pleura pulmonalis, and pleura costalis, may lead to a communication between the pulmonary air cells and the interstices of the common cellular tissue.

But, an injury of any cavity to which the breath has access, may be followed by some degree of emphysema. Thus, the lachrymal canals have been burst by blowing the nose violently, and emphysema of the eyelids and upper part of the face have been occasioned. Fractures, disease, necrosis, &c. of the frontal sinus, and fractures of the upper jaw-bone, implicating the nasal duct, have had the same effect. This kind of emphysema, however, never proceeds far.

The swelling, resulting from emphysema, has a tendency to spread, perhaps, with greater rapidity than any other with which we are acquainted, not even excepting that from internal effusion of blood. It is unattended with heat, pain, fluctuation, or discolouration of the skin. It is soft, tense, and elastic, rising up or down as the pressure of the finger is removed from it. A crepitation is also perceptible in handling it, caused by the air changing its place in the interstices of the cellular tissue. If you press upon one part of the swelling, you not only feel, but see the effects of the air produced by its passage into the contiguous cellular tissue. If you strike the part briskly with your finger, a dull sound, compared to that of a wet drum, may be distinguished.

Our case exemplifies the success of the ordinary treatment, where the disease ceases to extend itself. After a day or two, the period when the wound in the lung begins to be closed with fibrine, the bleeding was practised with the view of diminishing the congestion of the lungs, and the risk of thoracic inflammation and extravasation. It was practised also for the relief of the cough. Even had there been no emphysema, and merely a

broken rib, with cough, it would have been proper.

The broad roller was applied round the chest to keep the broken bone steady, and make the patient breathe by the diaphragm and abdominal muscles, leaving the intercostals quiet. This compression of the thorax with a bandage answers, when the quantity of air confined in the sac of the pleura is not above a certain quantity. In the contrary case, it cannot be endured, because it resists the escape of the air from the pleura, and thus augments the pressure on the lungs, mediastinum, and diaphragm.

Under such circumstances it should be removed, and the sac of the pleura cautiously punctured; for I believe, with Depuytren, that superficial punctures and scarifications will now be inefficient. But, remember that the occasion for puncturing the pleura will depend upon the urgency of the interruption of breathing, and that even this may partly depend upon other complications, especially extravasation of blood in the pleura.

The calomel and aperient saline medicine were administered to relieve the febrile disturbance, and to lessen the risk of thoracic inflammation; while the other medicines, the *mistura cetacei* with compound tincture of camphor, *vinum ipecacuanhæ*, and spirit of nitric ether, were given to appease the cough, which, in injuries of the ribs, and more especially in emphysema, is a source of considerable annoyance, and of injurious consequences with respect both to the fracture and diffusion of air.

Then, gentlemen, if you wish to follow up the subject of emphysema further, and view it as an interesting medical and pathological inquiry, you must study it in other forms. For instance, in that where air collects in the submucous cellular tissue of the alimentary canal from inflammation or disease; in that where, in consequence of certain pathological states, it collects under the serous covering of the lungs; or in others, where the source of the air, in the cellular tissues, is in the digestive canal itself. Lastly, the *pulmonary vesicular emphysema*, consisting in an enlargement of the air cells, or rather of the obliteration of many small air cells by their conversion into larger ones, would be a case deserving your attention, and one on which the celebrated Laennec has delivered valuable instruction. However, this does not strictly accord to the commonly received definition of emphysema.

ORATION

DELIVERED BEFORE THE MEMBERS

OF THE

ROYAL MEDICAL SOCIETY
OF EDINBURGH,

AT THE

CELEBRATION OF THEIR CENTENARY,

February 17, 1837.

By W. B. CARPENTER,

Senior President of the Society; Member of the Royal College of Surgeons, London; and President of the Royal Physical Society, Edinburgh.

Gentlemen,—A hundred years have now elapsed since a few individuals studying medicine in the University of Edinburgh, then in the dawn of its subsequent lustre,—individuals at that time unknown to fame, distinguished only by their ardour in the pursuit of knowledge, associated themselves together for the purpose of mutual assistance and improvement in the cultivation of Medical Science. The association thus commenced was not suffered to decline, as too frequently happens in similar cases, when no longer animated by the presence and activity of its founders. Their spirit still remained, for their energetic zeal fell, like the mantle of the prophet, upon their successors; and a century of almost uninterrupted prosperity has raised the Medical Society of Edinburgh to a station of unequalled dignity and importance.

Numbering at its commencement but six obscure students, it now comprehends the *élite* of the medical profession in this country; and not only does it spread its ramifications into the most distant quarters of the globe, wherever British skill and talent have been called into requisition, but the greatest luminaries of our science in foreign schools have thought it an honour to be enrolled amongst its members. Unpossessed at its origin even of "a local habitation and a name," and deficient in the means of collecting and amassing the records of past experience, it is now incorporated by Royal authority, and master of an elegant and commodious edifice, well stored with the literary treasures of bygone ages, and the accumulating wealth of the present. Instituted for the purpose of individual im-

provement, it has become a mighty engine for the advancement of the science to which it is devoted; and I assert with little fear of contradiction, that it has exercised an influence on the progress of medicine during the last century, second only to that of the Academic Institution with which it is connected, and many of whose brightest ornaments have been numbered amongst its members.

It would at any time be interesting to trace the history of an association whose career has been so remarkable—to inquire into the causes of its origin—to follow the progressive stages of its growth—to investigate the nature and extent of the influence which it has exercised on the individuals composing it, as well as on medical science in general, and to examine what there is in its original plan, its subsequent constitution, and the circumstances in which it has been placed, which has contributed to maintain it in a degree of prosperity, and to an epoch in its existence of which no similar association can boast. But with how much more propriety may these topics engage our attention when this epoch is the special occasion of our assembling here; when the social festival by which we are commemorating the Centenary of the Royal Medical Society of Edinburgh has called from the active duties of their profession, or from their calm and dignified retirement, so many of its old and distinguished members, to join with their younger friends in testifying the advantages which they have derived from it, and to stimulate them to the pursuit of the same honourable and successful career; and when the beginning of a second century of its history, recalling to our minds the commencement of the first, bids us acknowledge our debt of gratitude to the founders and supporters of an institution by which we have so largely profited.

The early history of our Society is so intimately connected with that of the progress of Medical science during the same important epoch, that the relation of the one necessarily involves much detail with regard to the other; and as it is evident that the position of any branch of knowledge at a given period cannot be justly estimated unless the prominent events in its previous history are rightly understood, I shall make no apology for the introduction of a brief sketch of the more important changes in this department of philosophy previous to the commencement of the eighteenth century.

As in the infancy of society we trace the influence of personal strength and prowess in raising their possessor to the regal authority, so may we observe that intellectual superiority conferred a no less absolute domination over the minds of the ignorant and superstitious vulgar. The history of the ancient mythology records the honours of deification to have been conferred alike on the warrior and on the sage—on him who improved the arts of life, as on him who devoted himself to its prolongation. It may be surmised, that to a remnant of the same spirit, carefully fostered by the objects of its veneration, and kept up by that restriction of knowledge to a few which necessarily resulted from the want of means for its diffusion, we may attribute the blind deference to individual authority which both in religion and science retarded in so remarkable a degree the progress of mental illumination in succeeding ages. Thus it was that the taste for abstract reasoning and refined speculation which pervaded the ancient schools, was perpetuated by the influence of Aristotle in the world of general science, and by the authority of Galen in medicine, for nearly two thousand years. The decline of the ancient schools of philosophy was succeeded by that long and dreary interval in which the world was overclouded by a dismal gloom, unbroken save by the coruscations of some brilliant intellect, which glared like a meteor through the darkness of ignorance and superstition, and then vanished without leaving a trace of its existence. During the three centuries succeeding the extinction of the Saracenic school in Spain, Medicine, which had there found a temporary refuge, fell, like every other science, into the lowest state of degradation. The metaphysics of Aristotle, adapted to the existing state of civilisation and learning, and the relations subsisting between the civil and ecclesiastical powers, gave rise to the scholastic philosophy, whose domination during the middle ages was so severe and universal. The spirit of slavish deference to authority was that which characterised the age; it paralyzed the efforts of those enlightened men who sought to free the world from this moral slavery, and entwined itself with parasitical fondness round the majestic column of revealed truth. Even in the darkest periods, however, the philosophic historian may trace the glimmering of that light which burst with

full splendour upon a subsequent age.* The gradual abolition of the feudal tyranny, the downfall of the Eastern empire, and the consequent revival of learning in Europe, the invention of the art of printing, which has been most justly said to "deride the havoc of time and barbarism," and the discovery of a new continent, were events of which any one would have been important it itself; whilst the conjoined effect of all was to produce a total revolution in the established modes of thinking, whether in religion, philosophy, or science.

One of the first effects of this revolution was to direct the attention of the learned to the original authorities on each of these subjects. Whilst Luther and his followers declared that the Scriptures are to be regarded as the sole guide to sacred truth, and separated their doctrines from the additions of a corrupted church, the students of philosophy and medicine had recourse to the genuine writings of Aristotle and Galen, which, after having been so long concealed in the libraries of Constantinople, were now most advantageously substituted for the imperfect and erroneous transcripts which had been employed in their stead. It required a further advance in the education of the age, before the simple astronomical doctrines of Pythagoras could supersede the cumbrous system which had usurped their place; and before the purer principles of Hippocrates, united to the spirit of careful observation which he so strongly inculcates, could be preferred to the more showy hypothetical structure erected by Galen and his followers.

It cannot but be esteemed as peculiarly fortunate that at this epoch, so important in the history of the human mind, the revolution in philosophy was conducted by two individuals possessed of intellects so exalted, of motives so disinterested, and of situations so favourable as those of Galileo and Bacon. These two great men arrived at the same result by different means, and thus strengthened and confirmed each other's exertions. The original and sagacious mind of Galileo led him to test the correctness of the received dogmas, by an appeal to experi-

* "There was always a faint twilight, like that auspicious gleam which, in a summer's night, fills up the interval between the setting and the rising sun."—*Harri's Philosophical Inquiries*, Part III. chap. i.

ment; the comprehensive learning and deep penetration of Bacon convinced him of the futility of the ancient mode of philosophising, both from the barrenness of its results, and from its inconsistency with the structure of the human mind. Whilst Galileo has perhaps the strongest claim to be considered the father of experimental philosophy, Bacon, as Dr. Thomas Brown justly remarks, was the reformer, not of physical but of mental science.* His comprehensive genius, surveying the whole panorama of nature, seized upon the highest principles of philosophical investigation, and traced out the method to be followed in bringing them to perfection; whilst his prophetic eye, foreseeing the results which were afterwards to be attained, enabled him to delineate a system of science which had not yet begun to exist.

In tracing the history of human improvement, it is most interesting to remark, the characteristics of more enlightened ages, shadowed out in the minds of men who were in advance of their time, but who were prevented by the depressing influence of the systems of error and ignorance in which it was then their lot to be placed, from rising to those exalted views which more unshackled, though perhaps not more powerful, intellects have attained. Thus in the writings of Hippocrates may be discerned a glimpse of that great and fundamental truth to which Bacon was the first to give full utterance, "that in every science, the basis of all our knowledge is the accurate observation of actual phenomena, and that the correct generalization of these phenomena should be the sole foundation of all our reasoning."†

The science of Medicine was not slow in experiencing the benefit of this general reformation. The authority of Galen

had been gradually undermined by the palpable errors which the zealous pursuit of anatomical investigation displayed in his works; the preference given to Hippocrates gained a corresponding increase; and as a necessary consequence, the habit of correct observation was confirmed, and the value of the observations was more justly appreciated.** The splendid anatomical and physiological discoveries of Harvey and Asselli, combined with the philosophical basis given by Boyle to chemical research, to extend the boundaries of our science, and to purify it from its grosser errors. At this period of the history of medicine a remarkable analogy may again be traced with the corresponding era in the progress of general science. The age of theories was not yet past; though the abstract speculations of the ancient schools were rapidly giving way before the accumulation of opposing facts, the framing of hypotheses was found too pleasing an employment to be relinquished; and the philosophy of Descartes, and the chemical and mathematical theories of medicine may be regarded as having alike contributed to the overthrow of the ancient systems, and retarded the progress of true science. The former was destined speedily to yield to the gigantic intellect of Newton; the latter contested their places with other theories of a similar tendency, until the Newtons of physiology and medicine appeared in the persons of Haller and Cullen. It was reserved for them to complete the triumph of the inductive philosophy, by demonstrating the practicability of its application to the sciences which were regarded as beyond its pale, and to establish, on a sure basis, the true method of advancing their progress.

You may perhaps consider, Gentlemen, that I have wandered far from my original topic in presenting you with this historical retrospect; but my object has been not so much to sketch the progress of medicine as a science, as to trace the successive changes in the mode of pursuing it, in which this Society had afterwards so important a share, and which afford us an insight into that deeply interesting branch of inquiry which I might denominate the self-education of the human race.

In the revolutions of science, as in those of religion, or of our political institutions, much is frequently due to the

* "We must not forget," says this profound metaphysician, and eloquent writer, "that the temple which Bacon purified, was not the temple of external nature, but the temple of the mind; that in its innermost sanctuaries were all the idols which he overthrew; and that it was not till these were removed, and the intellect prepared for the presence of a nobler divinity, that Truth would deign to unveil herself to adoration;—as in the mysteries of the Eastern religions, in which the first ceremony for admission to the worship of the god, is the purification of the worshipper."—*Brown's Lectures*, vol. i. p. 28.

† Bostock's History of Medicine, p. ix.

* Bostock's History of Medicine, p. xlvii.

commanding influence of a single intellect, or perhaps more commonly to the union of a few men of congenial views, and corresponding objects. But that their labours may not be fruitless, there must have previously existed a certain preparation in the public mind, without which their exertions can be but little effectual towards their designed end.

This, it appears to me, is the explanation at once of the origin and early success of the Medical Society. The hour and the men were both come. Living at a period of remarkable mental excitement, when the splendid discoveries of the seventeenth century, and more especially the spread of the Newtonian philosophy, were giving a stimulus to the investigation of truth in every department of science, and when the medical world was the arena of fierce controversy between opposing sects, its judicious founders adopted the principles of the inductive philosophy; and determining to consider nothing as proved until submitted to the test of experience, they candidly examined the doctrines of their teachers, and formed their own opinions as to their validity.

And, Gentlemen, it is to be recollected that however evident the accordance of such a proceeding with the principles of sound philosophy, or even with the dictates of common sense, may appear to us at present, it must have been regarded at the time as a daring innovation. The period of which we are speaking still exhibits the remains of that subservience to authority which characterised the dark ages of science. The names of Boerhaave, and Stahl, and Hoffman, were substituted by their respective followers for those of Galen and Hippocrates; the same blind reception of their dicta, the same submissive obedience to their injunctions prevailed in the schools over which they presided, as in those of ancient Greece; and their pupils thought themselves as much bound to maintain and propagate the opinions of their preceptors, as did those of Aristotle and Pythagoras of old. Though the objects of idolatry were changed, the temple and the worship still existed, and adoration was still paid by their blinded votaries.

I need scarcely remind you, that at the period of the formation of our Society, the Medical School of Edinburgh was rapidly advancing towards the proud eminence which it afterwards occupied. It was only about ten years previously that a regular Faculty of Medicine had been established;

and to the talents and industry of the illustrious men who were then introduced into the University, may be traced much of its subsequent renown. Its energies were cramped, however, by that spirit of system which still universally prevailed in Medical Science, and which was not long before so predominant in every school of philosophy, that Bacon lamented it as an evil inseparable from Universities. All the Professors who took an active part in the duties of instruction, had studied under the illustrious Boerhaave, whose doctrines then maintained their highest celebrity; and in the school of Edinburgh, formed upon the model, and succeeding to the eminence of that of Leyden, his principles continued for more than forty years to hold unlimited sway. The honour of the introduction of more correct views, and the final overthrow in this country of the hypothetical systems of former times, is due to the Medical Society, whose origin it is time that I should now detail.

The deficiency of any authentic records of its early transactions is fortunately supplied in part by the recollections of its oldest members; and in the writings of Dr. Fothergill, we find the following elegant account of its commencement. "Several students, at that time, the foremost in application and in knowledge, fired by the example of their masters, who had nothing more at heart than the improvement of those who committed themselves to their tuition, formed themselves into a Society for their mutual instruction, and advancement in their studies. Every student of a certain standing who distinguished himself by his diligence, capacity, and conduct, was initiated into this little assembly. Here the opinions of the ancients, of their contemporaries, nay, the doctrines of their masters, were freely discussed; and two of the members were always charged with the task of providing instruction and entertainment for the next meeting of the Society. Questions, no doubt, were here disputed and decided, which long experience would have declined; but it exercised their faculties, gave them both sides of arguments, taught them to doubt, and habituated them to observation." A more minute and circumstantial account, which it is not necessary here to quote, is given by Dr. Lettsom in his Memoir of Dr. Fothergill; his information was probably derived from one of the original founders of the Society, who has recorded the names of his coadjutors.

You will naturally inquire, Gentlemen, who were the individuals whose enlightened spirit shed such lustre over the humble sphere of their exertions; did the flame of intellectual zeal maintain a steady radiance during their subsequent career; or was this a transient effort of youthful enthusiasm, whose glow was speedily extinguished by the very energy of its combustion. Of the six founders of our Society, three, at least, rose to eminence in after life. Dr. Cleghorn is honourably distinguished by his work on the diseases of Minorca (which owes its origin to the suggestion of his friend Fothergill), and subsequently to its publication he was appointed Professor of Anatomy in the University of Dublin. Of Dr. Russel, we have also a literary memorial in the Natural History of Aleppo, a work which was long regarded as a model for similar compositions. It is not a little remarkable that, at a subsequent period of his life, when engaged in practice in the English metropolis, he was mainly instrumental in the establishment of the London Medical Society. In this undertaking he was assisted by many who remembered the benefits which they had derived from that of Edinburgh; and the oldest institution of its kind in England may thus be considered the legitimate offspring of that whose nativity we are now commemorating. If further testimony were wanting to the merits of Dr. Russel, it is afforded by the beautiful tribute of the accomplished Fothergill. "For my own part," he says, "when I recollect what I have lost in him, the sensible, firm, and upright friend—the able, honest, and experienced physician—the pleasing, instructive companion of a social hour—expression fails me." It may be regretted that Dr. Cuming has left us no literary record of his eminence; but it is enough to know that he not only attained great local reputation as a practitioner, but that he remained during life the beloved friend of Fothergill. Of the three remaining founders of this Society, Dr. Hamilton, Dr. James Kennedy, and Mr. Archibald Taylor, history has transmitted us no information; it may, however, be inferred, from an expression of Dr. Fothergill's, that they were cut off in the midst of their usefulness by premature death.—But, Gentlemen, as long as this Society shall exist, their names shall not pass away unhonoured and unknown; for of them may it be said in the language of the noblest epitaph ever written, "*Si quæris monumentum—circumspice.*"

It was in the year 1734 that the Association was formed, which may be regarded as having originated the Medical Society; but it was not permanently constituted until three years afterwards, at which date the list of members commences, which is the earliest of our documents still existing. In this interval, the infant Society, then struggling for existence, was strengthened by the junction of two individuals, of whom each contributed much to its subsequent eminence, and one exercised a most important influence on its destiny. I have mentioned that of the founders of this institution, three at least enjoyed through life the esteem and friendship of the illustrious Fothergill; and it is interesting, therefore, to believe that this tie was formed by their companionship in an undertaking so important and so difficult. We cannot hesitate in the conviction, that to the "singular combination of vigorous power of mind, and chaste integrity of manners," which obtained for him so high a subsequent eminence, this Society is largely indebted for its early usefulness and reputation. To Dr. Fothergill and his friend Cleghorn, we probably owe its continuance, when the dispersion of the original members threatened its downfall.

To Dr. Cullen, the early obligations of the Society are probably not inferior. It appears from one of his letters which is still extant, that he did not neglect to avail himself of the advantages which it presented even in the first year of its existence; and though no record of its transactions has come down to us, we can scarcely doubt that he there exhibited the independent and inquiring spirit, which, under the guidance of unwearied industry and insatiable desire of distinction, afterwards raised him to the loftiest eminence among the benefactors of our science. And while we believe that here the "burning and shining light" of his powerful genius unveiled its dawning lustre, and that the glow of enthusiasm which he here displayed in the pursuit of knowledge must have kindled a corresponding ardour in the breasts of his associates, are we not also justified in supposing, that the mental illumination thus diffused, was reflected back with augmented brilliancy upon himself, and that here his intellectual progress was cheered and supported in its advancement towards the glorious splendour of "perfect day."

(To be continued.)

COMPLETE MEMOIR ON
PHTHISIS LARYNGEA,
 EXTRACTED FROM THE UNEDITED WORK
 OF MESSRS. TROUSSEAU AND BELLOC,
 FOR WHICH A PRIZE WAS AWARDED BY
 THE ACADEMY OF MEDICINE IN PARIS.

*What is meant by Phthisis Laryngea ?
 What are its Organic Alterations ?
 its Causes ? its Species ? its Termination ?
 What is its Treatment ?*

CHAPTER IV.

(Continued from p. 28, No. 1.)

SYMPTOMS.

General symptoms are seldom seen in Phthisis Laryngea, unless the disease be at the acute state, or when anatomical disorders have attained great development. When the disease becomes chronic the local symptoms are alone perceptible, and to these symptoms the practitioner must give his whole attention.

Alteration of the sound of the voice. In the first stage the voice becomes weak and hoarse. This hoarseness is greater in the evening than in the morning, and increases when the patient goes from a warm to a cold situation; and *particularly* from a cold to a warm room.

This hoarseness is more intense if the patient be hungry; and in women it also increases at the period of menstruation. The abuse, or sometimes the simple use of coitus, produces the same effect.

The hoarseness is intermittent in the first stage of the disease, but it soon becomes habitual, and continues so till the termination of the malady.

Aphonia. Aphonia is generally a serious symptom, often arising from a deep alteration of the larynx. We are, of course, understood to mean continual aphonia, for a simple catarrhal swelling of the mucous membrane may often occasion a total loss of voice. Aphonia, like hoarseness, is greater in the evening than in the morning; when this modification exists, there is reason to suppose that the disorders are not yet of a serious nature.

Inequality of the voice.—The voice, though sometimes merely hoarse, is generally equal in conversation; but when the patients lay a stress on certain syllables, the voice becomes shrill and squeaking.

Cough.—Coughing is usually more frequent in Phthisis Laryngea than in diseases of the chest. Its sound is always similar to that of the voice, therefore it

is hoarse when the patient is hoarse, and weak when aphonia exists.

Expectoration.—Expectoration is mostly mucous, transparent and tenacious, more or less abundant according to circumstances; sometimes clotty, puriform yellow, streaked with blood. These clots are expectorated by a slight effort, unconnected with cough. This symptom shews that there is ulceration in some parts of the larynx.

Pain.—Most patients suffer but little pain; it sometimes happens that it is less at the end than at the beginning of the disease.

Swallowing causes more pain than speaking or breathing, which leads the patient to believe that lesion exists in the pharynx, not in the larynx. But it is easy to account for this phenomenon, as the pharynx completes the front part of the larynx, and the same mucous membrane covers the whole.

Symptoms ascertained by sight.—Sight affords but little assistance in the discovery of disorder existing in the larynx, nevertheless the careful examination of the throat should on no account be neglected. The disease often commences in the pharynx or its appendages, and it is right to see whether these alterations present any special characteristic. This remark is important, especially as regards Phthisis Laryngea Syphilitica. The epiglottis may sometimes be seen, though this is seldom the case. We have only met with two patients in which it was perceptible. The shape of the alteration of the epiglottis may lead to a supposition of the nature of the alteration of the larynx; an attempt to discover it should therefore always be made. The handle of a spoon should be bent, placed on the tongue, and drawn forward; then if the patient screams, the fibro cartilage is perceived: it is elevated while the shriek lasts, and then falls.

Symptoms ascertained by the touch.—Some authors consider crepitation as a pathognomonic symptom of a serious alteration of the cartilages of the larynx. We do not attach the same importance to this crepitation. It exists among certain individuals who have a healthy larynx, if the organ be moved: it then depends on the cartilages rubbing against the cervical vertebræ. This symptom must therefore be looked on with the greatest circumspection.

It is extremely difficult for the finger to reach the inside of the throat, as its introduction causes vomiting. Yet, by

means of the finger, serious alterations of the epiglottis and the superior orifices of the larynx are sometimes ascertained.

Signs furnished by respiration.—In the first period respiration is scarcely affected, but, as the disease increases, *anhelation* or *panting* comes on, and continues till death, unless the course of the disease be arrested. This panting may depend on two causes :

1st. The patient may be already weakened by disease, then panting is caused by the diminution of muscular strength.

2nd. This oppression may be caused by the orifice of the lungs becoming small, in which case the patient, in the first instance, suffers from an attack of asthma ; then all fits generally begin in the night, respiration is easier in the day.

Later on the fits increase, if the oppression is lasting, the patient requires to be propped up with pillows in bed ; breathing then has a wheezing sound, and the noisy respiration is prolonged.

Real paroxysms of orthopnea then arise, during which the anxiety is extreme, and suffocation imminent. In the course of fifteen or twenty days after this period the patient generally falls a victim to suffocation.

Deglutition.—The mode of deglutition does not appear to require any great consideration as regards the form and extent of the lungs and its appendages. We have given several cases which prove that, in certain patients, the epiglottis being perfect, food nevertheless, falls into the larynx, or returns through the nostrils ; while in others, when the epiglottis is destroyed, or nearly so, deglutition takes place without difficulty.

Different symptoms according to the species of phthisis laryngea.

Phthisis laryngea syphilitica.—Phthisis laryngea syphilitica has frequently symptoms, the knowledge of which may be essentially useful ; for instance, the alteration of the larynx is an extension of the disease already found in the canals ; and in this species of disease deglutition is generally more painful than in any other. The touch is of greater service here than in simple phthisis laryngea.

We have given the case of a patient, in whom we have discovered the existence of enormous vegetations on the pharynx, and even on the superior part of the larynx. This latter observation is applicable to the cancerous phthisis laryngea, but if the seat of the evil be exclusively in the larynx, and beyond the reach of

the finger, the previous state of the patient and other concomitant lesions must then throw some light on the nature of the alteration. Such then, whatever may be the state of the patient, is the best mode of investigation ; but when possible, the practitioner should insist on the touch.

Tuberculous Phthisis Laryngea.—Phthisis laryngea appears to us of a tuberculous nature whenever it exists with confirmed pulmonary phthisis, therefore, the symptoms of this latter affection can alone throw a light on the diagnosis.

Cancerous Phthisis Laryngea.—We should be inclined to think that this species of disease might be recognized by the touch. If a tumour be felt in the larynx, and symptoms of cancerous affections exist at the same time, there could then be no doubt as to the nature of the disease, but these signs seldom exist simultaneously. In the case of cancerous phthisis laryngea we have given, the patient felt no lancinating pains, and that yellow complexion, generally considered as a characteristic of cancer, did not exist, an exterior tumour was manifest before we were able to decide on the nature of the case.

CHAPTER V.

TERMINATION.

1st. We have examined in this chapter how phthisis laryngea can engender pulmonary phthisis, and again how pulmonary phthisis can give rise to phthisis laryngea : we have given our opinion on the connexion between phthisis laryngea and the swelling of the mucous membrane, improperly called *œdema* of the glottis, and we have said a few words respecting its cure. We find, on examination, in persons dying of pulmonary phthisis, that consumption is owing to other disorders besides those existing in the lungs. Thus the cough that fatigues all the muscles, fever, perspirations, diarrhoea, are more immediately fatal than pulmonary lesion itself.

We therefore conclude, that the death of a patient cannot be attributed to phthisis laryngea, if the lesion of the larynx exist alone, but it must be proved that it existed in the first instance, and gave rise to all the ensuing accidents.

We have given several remarkable cases of simple phthisis laryngea, among which is one related by Portal ; death often takes place before the ulceration of the larynx has caused real consumption. The difficulty of breathing, sometimes

the impossibility of deglutition, the violence of the cough, suffice to cause a fatal termination before the patient reaches a state of marasm. As to the tuberculous phthisis laryngea, the cases we have related, give rise to the following reflections:

1st. Tuberculous pulmonary phthisis generally shews itself first, and the larynx only becomes affected in the last stages.

2nd. In some peculiar cases, the tuberculous lesion commences with the larynx, and invades the lungs at a later period, this, however, very seldom occurs.

3rd. Sometimes the phthisis laryngea and the pulmonary phthisis arise and increase conjointly.

4th. In this latter case, the lesion appears sometimes to exist exclusively in the larynx, on account of the predominance of the symptoms of the larynx, and the difficulty of ascertaining the lesion of the lungs by stethoscopic signs.

One of the most fatal results of the phthisis laryngea is the swelling of the borders of the glottis; we have devoted a whole paragraph to shew the relation existing between the disease that authors have called *aniga laryngea œdematosa*, and phthisis laryngea.

Connexion of angina laryngea œdematosa with phthisis laryngea.—Our limits will not permit us to enter into a discussion on this important point of pathology, we shall, therefore, merely give a slight sketch of the conclusions resulting from this discussion.

Boyle very justly divided the angina laryngea œdematosa into primitive and consecutive.

When primitive, it is almost constantly the result of an inflammatory fluxion of the larynx, or of the neighbouring parts, and is precisely of the same nature as those described by Boerhaave. — Aph. 801—802.

When it is consecutive, that is to say, caused by an organic lesion of the larynx, or its appendages, it may be inflamed or active, or not inflamed or passive.

In the first instance, the inflammation has extended from the affected part to the mucous membrane of the larynx.

In the second, the serosity accumulated under this membrane is only owing to the congestion of liquid tumefaction round the loss of substance.

In both cases the angina laryngea œdematosa, having as an origin an ulcerated spot, cannot be considered as independent of inflammation.

Whatever be the cause of phthisis

laryngea, it may justly be considered as the most frequent occasion of angina laryngea, œdematosa.

Termination by cure.—The chance of saving the patient must depend on the attention given in the early stage of the disease. If the affection has made progress, and arrived at a state of marasm, there can be but little hope.

In our chapter on the treatment, there are, however, several cases in which active medicine has prevented accidents, and restored health to patients who were in imminent danger. Morgagni, (epist. 44, art. 55,) gives a remarkable example of the cure of an old man labouring under syphilis, which had brought on great alterations in the larynx.

From these considerations we may conclude, that, if when the alteration of the larynx has reached a certain pitch, there is but little chance of saving the patient, yet all hope of success must not be abandoned.

CHAPTER VI.

TREATMENT.

Repose of the Organ.—Repose of the organ is one of the most important conditions to which the patient must submit; however, Messrs. Trousseau and Felloc have given several cases which serve to prove, that cures have been obtained without this condition meeting with rigorous attention.

Antiflogistics.—Bleeding has, in our opinion, been found the most efficacious treatment at the commencement of phthisis laryngea, we prefer bleeding in the arm; if leeches be applied to the part affected, they must be very numerous.

If there be reason to suppose that the affections of the larynx is owing to a suppression of the menses, leeches must be applied to the thighs, or to the vulva; if to a suppression of hemorrhoids they must be applied to the anus.

Emollient applications on the larynx seem to do more harm than good, owing to the quantity of blood they draw to the part affected.

Revulsives.—Revulsives are generally found much more efficacious than bleeding, when the disease is of long duration.

Thus, advantage may be derived from the application of blisters, but they must suppurate a long while; they must be put on the nucha, particularly for men, who, on account of their thick beards, would be too much inconvenienced by having them on the fore part of the neck.

Setons and potential cauteries applied to the front of the neck are sometimes found very beneficial.

Revulsives applied at a distance from the affected part have never appeared to us very efficacious.

Narcotics.—Narcotics are useful to relieve pains and cough. Extract of datura stramonium and belladonna rubbed on the interior part of the neck, salts of morphia introduced by the endermic method, merit the preference.

Topical Medication.—The fumigations used in diseases of the larynx are either the vapour of pure water, or mucilaginous, or balsamic, or aromatic; the dry fumigations are the smoke of pitch, resin, snuff, hyoscyamus, cinnabar, sulphuric acid, &c. &c. &c.; but we have given up all these remedies, for they reach the lungs.

Topical Liquids.—The topical liquids we most frequently apply, are the solution of nitrate of silver, sublimate, sulphate of copper, or nitrate acid of mercury. We prefer nitrate of silver, from the use of which we have never met with any serious accident. The solution of sublimate, employed according to Mr. Malapert's method, in the proportion of one to eight grains of distilled water, has proved successful in some cases of syphilitic ulcerations, which we have related in our work.

To convey these liquids on the throat topically, we take a fine round sponge, six or eight lines in diameter, fastened to a bit of whalebone, forming at one end an obtuse angle of about ninety-five degrees.

By means of this small instrument, we can reach both sides of the epiglottis, the pharynx, and the upper part of the larynx.

We also adopt the following plan:—

We have had fitted to a small silver syringe, like Anel's, a canula, five inches long, and bent at the end; we fill the syringe $\frac{2}{3}$ air and $\frac{1}{3}$ solution of nitrate of silver, then the canula being introduced into the fauces opposite the larynx, we push the piston quickly, and the liquid, mixed with the air in the syringe, falls on the upper part of the larynx and the cesophagus.

The patient immediately has a fit of coughing, which should cause no alarm; he should directly take a gargle of hydrochloric lemonade, or salt water, which decomposes the solution of nitrate of silver that is not combined to the tissues.

The numerous and very interesting
No. 2.

cases related in our memoir prove the efficacy of this energetic remedy.

Pulverulent remedies.—In insufflations into the larynx, we frequently have recourse to pulverulent remedies of different nature; among which we shall mention, in an inverse order to their energy, subnitrate of bismuth, that may be employed pure; alum, acetate of lead, sulphate of zinc and copper.

Calomel and red precipitate have furnished very striking results in cases of syphilitic and other ulcerations of the mucous membrane of the larynx. These powders, excepting subnitrate of bismuth, may be mixed with powdered sugar candy, in various proportions, suited to the activity of the remedies employed.

The insufflations of mercurial powder must not be repeated more than two or three times a week in the first instance. Without this precaution the injury might be increased.

General Mercurial Medication.—We have collected and annexed to our memoir a great number of cases taken in our own practice, and in that of others. These cases are highly interesting, and most decidedly prove the advantage of mercurial treatment carried even to salivation in desperate cases of phthisis laryngea. We cannot, therefore, too strongly recommend this medication for serious diseases of the larynx, whether syphilitic or not.

Tracheotomy.—Notwithstanding the ability with which the treatment may have been directed, accidents may increase, and the patient's life be endangered by the air not reaching the lungs. In this case, tracheotomy must be had recourse to, it offers a fair chance of success, and could not be neglected without a failure of duty, whatever may be the opinions of some practitioners, influenced, no doubt, by the opinions of the ancients.

We have given many instances in which the life of the patient had been saved by opening the trachea; at all events, as this operation is never performed unless there is imminent danger of suffocation, a canula should be introduced into the aperture of the trachea, and this canula should be of sufficient dimensions to permit the free passage of the air to the lungs. The physician, then, having no fear of his patient being suffocated, can employ the necessary medication for the lesion of the larynx. When the larynx can perform its functions, the canula may be withdrawn, and

the wound soon heals. But if the affection has been so serious as to leave no hope that the air can ever go through the natural passage, the canula may be left in the upper part of the trachea. We have given an example of a patient who wore a silver canula ten years.

It might happen that after the operation was happily terminated, and the canula introduced, the disease was in its nature incurable. It then progresses till death becomes inevitable. Several cases of tuberculous phthisis laryngea and cancerous phthisis laryngea are of this kind; but even then the operation is well-judged, as it evidently prolongs the life of the patient.—*The Continental and British Medical Review.*

AN ESSAY
ON THE ORIGIN AND NATURE OF
TUBERCULOUS
AND
CANCEROUS DISEASES.

(Continued from p. 11, No. 1.)

READ TO THE MEDICAL SECTION OF THE BRITISH ASSOCIATION, ON THE 23RD OF AUGUST, 1836, BY RICHARD CARMICHAEL, M. R. I. A., CORRESPONDING MEMBER OF THE ROYAL ACADEMY OF MEDICINE OF FRANCE, ETC. ETC., AND CONSULTING SURGEON OF THE RICHMOND SURGICAL HOSPITAL, ETC. ETC.

Some modern pathologists have been at great pains to determine the nature of tuberculous formations by the shape and form in which they present themselves; but they might as well attempt to form just conceptions of the nature of those fungi which grow on the decaying surfaces of timber in damp wine vaults, or on the mouldering bark of the more ancient oaks and other forest trees, by a consideration of the shapes they assume, which vary according to the situations in which they happen to arise, as they are moulded and turned from their natural course by every barrier that happens to come into contact with them during their growth. An examination into their internal structure, on which the aid of the microscope may afford much light, is more likely to lead to an accurate knowledge of their true nature.

A consideration of the elementary principles of vegetables, carbon, oxygen, and hydrogen, when compared with those of

animals which are the same, with the addition of azot,* should induce us *a priori* to suppose that animal matter, whenever the vital principle is weakened or nearly extinguished, is more prone to fermentable changes, and consequently to the production of parasitic beings than vegetables, which arise in both kingdoms whenever a diminution of vitality loosens the bonds which tie together the component organic particles of which they are composed, and permits them to assume new shapes of existence. It is thus that the simplest forms of organic life are to be met with, as parasitic plants in the vegetable, and the entozoa in the animal kingdom, where every circumstance seems prepared and favourable for their production. The mischievous effects of parasitic plants in the vegetable world has long engaged the attention of the botanist and agriculturalist; and to those of the animal kingdom, which are still more general and destructive, I urgently call the attention of the profession and the public.

The analogous disposition to the production of parasites in both vegetables and animals has been long apparent to me, perhaps chiefly in consequence of the vast number of malignant cases, which during a long course of public and private practice have come under my observation. The most remarkable instance amongst them which excited my attention to this analogy was that of an old gentleman, whom I saw many years since, in consultation with Mr. Macklin. There were few parts of his body to be seen that did not betray the growth of cancerous formations. The forehead, nose, prominent parts of his cheeks, lower lip, breasts, testes, &c. &c. exhibited the schirrous, cartilaginous, or horny masses which cancer universally exhibits; and such was the general prevalence of the disease that I could not avoid remarking to Mr. Macklin, at the time, that this old man strongly reminded me of an ancient oak overspread and exhausted by fungi.

Carcinoma is in general a disease of the middle or advanced periods of life; but in some the predisposition is so strong that it may occur even before the age of puberty. Some years ago I examined, in conjunction with Mr. Peile, the body of a young woman twenty-one

* I do not here notice other primary principles which enter into the composition of living beings, such as sulphur, phosphorus, iron, lime, magnesia, soda, &c. &c.

years of age, who died of cancer of the womb; and I lately had an opportunity of observing extensive carcinomatous accretions in a girl of fourteen, whom I attended for nearly a year on account of a variety of complaints which evinced disease of nearly all the viscera of the different cavities. In making a post mortem examination, in which I was assisted by my friend and former pupil, Mr. Belton, we found tubercles or carcinomatous tumours in all the cavities. In the anterior lobes of the brain there were encysted fungous tumours about the size of wall-nuts. There was a large mass of a semi-cartilaginous substance in the anterior mediastinum. The lungs were tuberculated. Both mammae were enlarged, and presented the usual cartilaginous appearance of carcinoma, and the mesenteric glands were also in a tuberculated state.

I might adduce numerous other instances of carcinoma occurring at an early period of life, but the above are sufficient examples. In these two persons, who thus died its early victims, the countenance had the remarkable pale hue, with a tendency to lividness, called a leaden colour, to which I have before alluded.

It is to be remarked that Andral has made very similar observations respecting the colour of the skin in those predisposed to tubercular phthisis; he says, "observation has proved, that it (tubercle) has an especial tendency to grow in those individuals whose skin is very fair, and as it were *blanched and without any trace of colouring matter* in its capillaries. The colouring matter thus deficient in their skin is likewise so in their eyes, which retain the blue tint of infancy, and in their hair, which is light coloured, and also small in quantity. Their muscles are soft and slender, and show little contractile power; their blood is serous, and deficient in fibrine and *colouring matter*."

In chapter viii. of the second edition of my work upon Cancer, published in 1809, I have particularly noticed this peculiar character and colour of the countenance of those disposed to carcinoma and tubercular phthisis, and ascribed it to want of colouring matter in the blood. I have also in the same chapter related some post mortem examinations of those who died of external cancer, having at the same time tubercles in the lungs, and that on comparing the structure of one with the other (the cancerous mass with the tubercles) little or no perceptible dif-

ference was apparent. These facts, coupled with the various circumstances and analogical reasonings stated in this paper, afford, to say the least, a strong presumption, that pulmonary tubercles are more nearly allied to carcinoma than to scrofula.

One remarkable circumstance attending the transmutations of pulmonary tubercle and hydatids is, that in the last change of both one and the other the same identical appearances are presented. Thus in both we find a matter of a cheesy or putty-like appearance, with calcareous matter. I have already given sufficient proof that such is the last transmutation of hydatids; now I shall adduce one or two esteemed authorities, that tubercles in the lungs and elsewhere have a similar termination.

Carswell, speaking of the last transmutation of tubercles, at that period at which he infers that the disease had undergone a natural cure, says, "the tuberculous matter, whether contained in a bronchial tube, the air cells, or cellular tissue of the lungs, assumes a dry *putty-looking, chalky, or cretaceous* character;" and he has beautifully illustrated this fact in Plate iv. Fig. 4, of his *Pathological Anatomy*.

Monsieur Regnaud, in his accurate memoir on the Obliteration of the Bronchi, inserted in the *Memoirs of the Royal Academy of Medicine*, enumerates tubercles as one of the most influential causes. "In phthisical patients," he remarks, "it is not uncommon to meet in different points of the lung, particularly near the top of it, encysted or free masses, resembling tubercle, soft plaister, or dry chalk, varying from the bulk of a pea to that of walnut. These chalky masses, or those resembling dried tubercles, are contained in pouches more or less thick. The contents of these pouches are different: sometimes they are like tuberculous matter, oftentimes it is like wet plaister, at other times so dry as to crumble between the fingers; again it is found like chalk, resisting the edge of the scalpel, and it is not unusual to find small portions of a matter as hard as silex in their centre."

Andral observes, "we sometimes find tubercle acquires an unusual hardness and becomes transformed into a gritty mass, in which chemical analysis shows a notable quantity of phosphate and carbonate of lime; these salts are also found, but in much less quantity in ordinary tubercles, so that their cretaceous trans-

formation is merely a withdrawing, a re-absorption of the animal matter." He then gives the analysis, by Thenard, of tubercles in their natural state, before they had undergone any softening transmutation. He adds their analysis after they had undergone their last or cretaceous change. In both states it appears that carbonate and phosphate of lime enter largely into their composition. We may then infer that when hydatids and tubercles, like the animal which they infest, die, and undergo their last transmutation, their soft parts disappear, leaving only the earthy particles behind, which bid defiance to the process of putrefactive fermentation or absorption to remove. Now, as it does not appear from any known analysis that coagulable lymph contains phosphate and carbonate of lime, the inference is obvious that the prevailing theory respecting tubercles is wrong; and, on the contrary, as we find cretaceous matter containing both phosphate and carbonate of lime is always found in hydatids, the lowest order of entozoa at present acknowledged, a strong additional inference is afforded, that tubercle constitutes another and the last link of this class.

In the presence of those earths, even in the lowest animals, we cannot help observing something of that type upon which the Creator formed the entire animal kingdom. For as the nervous system is not, in zoophytes, or the lowest grade of animals, collected into distinct cords, but is universally diffused through their substance, so we find those earthy particles which form the basis of the skeleton of higher classes, diffused also through the system of these, the last link in the chain of animal life.

At the last meeting of the Association, my friend Doctor Houston read an interesting account of cysto-circi hydatids, found in the abdomen of an Axis deer. Bunches of soft tumours, varying from the size of a pea to that of an orange, were attached to the omentum and peritoneal folds of the different viscera. These were found to be the capsules of those hydatids. Now, although this animal's lungs were found to be filled with tubercles of which he died, yet Doctor Houston cannot see that there was any connexion between the one morbid appearance and the other. To my simple apprehension there appears to be a very close connexion, indicating a disposition in the creature to the production of parasitical animals, which in the abdomen

appeared in the form of hydatids, and in the lungs in that of tubercles, an opinion which is supported by a fact mentioned incidentally by Andral, who found, in conjunction with M. Dupuy, tubercles intermixed with hydatids of cysto-circus species in the lungs, heart, and muscles of a hog.

I have been informed from undoubted authority, that hydatids and tubercles have been very generally found in the bodies of dairy cows in Paris; and in fact we have sufficient data to conclude that tubercles and hydatids are produced in the tissues of all animals confined in menageries, or which, deprived of their natural exercise, are exposed to an unwholesome and vitiated atmosphere.

I have for some time been anxious to ascertain if tuberculous matter, before ramollissement commences, possessed a power of preserving its life at the temperature of the body from which it has been taken, and of resisting those fermentable changes to which all dead animal matter is subject. I was also desirous of trying an analogous experiment to that of Hunter, by which he ascertained that an egg is in possession of life. But since these ideas suggested themselves to my mind, I have not been able to procure any undecomposed tuberculous substance, fresh and sufficiently insulated from that of the animal matter in which it was imbedded, to admit of experiment.

The prevailing doctrine respecting tuberculous diseases has derived its chief support from Doctor Carswell's indefatigable labours in the field of pathological anatomy; and although I dissent from his views, there is not amongst his friends an individual who feels more disposed to give him the credit he so amply merits for his accurate descriptions and most satisfactory illustrations of tuberculous diseases. It is with reluctance, therefore, that I differ so materially in opinion from one who has done so much to advance the science of medicine: that reluctance is, however, in some degree diminished by the recollection that the doctrine I espouse has been supported by pathologists of the highest eminence; amongst others, Laennec, as we must infer from the following passage: his words are, "tubercles are accidental productions, that is *real foreign bodies which spring up* in the substance of the lungs, and may be developed in any other texture of the body." His translator and commentator, Doctor Forbes, incidentally acknowledges in a note that Laen-

nec believed in the independent vitality of tubercle, and observes, "that Laennec's views were called in question by Magendie, Cruveilhier, Andral, Lombard, and Boullard, whose researches, he says, "all tend to establish the proposition that tubercle, instead of being an accidental production, possessing a proper vitality, and developing itself by *intussusception*, like organised tissues, is in fact the result of a morbid secretion, a peculiar species of pus, an inorganic product formed by *juxta-position*." I trust, however, that I have adduced some strong facts and considerations respecting the parenchymatous substance of which tubercle is composed, and the laws of the animal economy, to evince that the views of this celebrated philosopher and physician were not erroneous.

(To be continued.)

THE ANATOMIST.

OSTEOLOGY.

The assemblage of bones composing the human body constitutes the skeleton, which is divided into head, trunk, and extremities.

The *Trunk* consists of three parts, the spine or vertebral column, the chest or thorax, and the pelvis.

The *Spinal or Vertebral Column*, situate in the posterior part of the trunk, supports the head, and is itself supported by the pelvis. The bones which enter into its formation are called *vertebræ*, of which there are two classes, the *true* and the *false*.

The *true vertebræ* are twenty-four in number, and are subdivided into three classes, viz. seven *cervical*, twelve *dorsal*, and five *lumbar*.

The *false vertebræ* are two, the *os sacrum* and *os coccyx*, both of which bones enter into the formation of the pelvis.

COMMON CHARACTERS OF A TRUE VERTEBRA.

A *ring of bone*, the opening of which is called the *spinal or vertebral foramen*.

The *Body*, a mass of bone placed anterior to the ring, thick, spongy, and presenting many small holes for blood-vessels.

Laminae, two lateral processes which pass backwards from the posterior part of the body, forming the sides of the ring.

Two transverse processes, which pass outwards from the sides of the *laminae*.

Four articular processes, two upon the upper and two upon the lower surface of each vertebra, which arise from the roots of the transverse processes, articulate with the vertebra above and below.

All these processes differ from the body in being formed of a more compact bony texture.

Four notches, two above and two below, which are formed by the *laminae* being grooved out where they join the body. Each of these, with the corresponding notches above and below, forms a lateral hole for the exit of the spinal nerves and the entrance of blood vessels, and is called the *intervertebral foramen*.

CHARACTERS OF THE LUMBAR VERTEBRÆ.

1st. They are the *largest* of the three classes.

2nd. The *bodies* are very broad transversely, of an oval form, deepened upon their upper and lower surfaces by a more compact lamina of bone, which, projecting beyond their bodies, render them concave from above downwards upon their fore part.

3rd. The *laminae* and spinous processes are broad, thick, and short.

4th. The *transverse processes* are long, thin, and horizontal.

5th. The *superior articulating surfaces* are oval, concave, and look inwards and backwards; the *inferior* being oval, and convex, directed outwards and forwards.

6th. The *spinal foramina* are of a triangular shape, and larger than in the dorsal vertebrae.

7th. The *notches*, particularly the inferior, are very large, and form larger foramina than at any other part of the spine.

DEVIATIONS.

The *last lumbar vertebra* has its body cut off obliquely upon its sacral aspect, so that it is much thicker before than behind. Its transverse processes also are short and rounded.

CHARACTERS OF THE DORSAL VERTEBRÆ.

1st. They are intermediate in size between the cervical and lumbar vertebrae.

2nd. Their *bodies* are thicker behind than before, and more convex transversely, assuming upon their surfaces a triangular rather than an oval form. On either side at the upper and inferior margins each body presents two small

depressions, the upper being the larger, which, with the intervertebral cartilage and the contiguous vertebræ form depressions for lodging the heads of the ribs.

3rd. *The laminae* are broad and strong.

4th. *The spinous processes* are long, prismatic, tuberculated at their extremities, and directed obliquely downwards.

5th. *The transverse processes* are long and directed backwards; on the extremity and anterior aspect of each is an oval articular surface for the tubercle of the rib.

6th. *The articular processes* are nearly vertical, the superior looking backwards, the inferior forwards.

7th. *The spinal foramen* is smaller than in the cervical or lumbar vertebræ, and is of an oval shape.

8th. *The notches* are situated anterior to the articular processes.

DEVIATIONS.

The *first dorsal vertebra* has a full depression for the head of the first rib, besides the half depression for the second; its body is longer in the transverse direction, its spinous process is strong and horizontal, and its particular processes are oblique.

The *10th*, *11th*, and *12th*, have each a full depression upon the body for the corresponding rib, but want the depression on the transverse processes: the *12th* resembles a lumbar vertebra in the shape of its body, and of its inferior articulating processes.

Characters of the Cervical Vertebræ.

1st. They are the *smallest* of the three classes.

2nd. *Their bodies*, deeper before than behind, and long transversely, are concave from side to side upon their upper surface, and concave from before backwards upon their lower.

3rd. *The laminae* are broad and thin.

4th. *The spinous processes* are short, horizontal, and bifid.

5th. *The transverse processes* also bifid and short, are grooved upon their upper surface for the spinal nerves, and perforated by a round hole at their bases for the vertebral artery, the direction of which is upwards.

6th. *The articular surfaces* are oval in shape, the superior being convex, and directed obliquely backwards and upwards; the inferior being concave, and

directed obliquely forwards and downwards.

7th. *The notches*, nearly of equal size, are small, and anterior to the articular processes.

8th. *The spinal foramen* is large and triangular.

Deviations.

The *first*, or *atlas*, consists of a large bony ring enclosing an irregular hole; instead of a body, which is absent, the anterior arch of the ring of bone presents a small tubercle before, and a smooth oval articular surface behind, for the odontoid process of the second vertebra. From the extremities of this arch the ring acquires great density and thickness, and presents upon its upper and lower aspects the articular processes, the superior of which, horizontal and oval from before backwards, look upwards and inwards, and articulating with the condyles of the occipital bone; the inferior circular, slightly oval, and directed downwards and inwards, to articulate with the second vertebra. The transverse processes are not bifid, but are pierced at their bases by the foramen for the vertebral artery, the direction of which is upwards and backwards, and behind the superior articular surface is a groove, which marks the continued course of this vessel. The spinous process is represented by a small tubercle upon the inner surface of the ring, corresponding to the articular surfaces, are two small tubercles, to afford attachment to the transverse ligament, which ligament separates the ring into two, the anterior being for the odontoid process, the posterior for the commencement of the spinal chord.

The *second*, or *axis*, is distinguished by the great length of its body, from the upper edge of which arises its large tooth like, or odontoid, process. This process presents anteriorly a small articular surface for articulation with the ring of the atlas, and posteriorly a second, which moves against the transverse ligament, whilst its apex presents an acuminate top, to which the check ligaments are attached. The laminae are very thick and strong, and terminate behind in the spinous process, which is likewise strong and bifid: the vertebral foramen is heart shaped, the apex being behind. The superior articular surfaces are convex, and directed a little outwards, whilst the inferior, looking downwards and forwards, are smaller and flat.

The transverse processes, not bifid,

are short and directed downwards, the aspect of the foramen for the vertebral artery, which its base being obliquely upwards and outwards; the superior notches are behind the superior articular processes, whilst the inferior notches are before the inferior processes.

The seventh cervical vertebra is larger than the others; its spinous process is long, not bifid and prominent, and the foramina, when they exist in the transverse processes, give passage to the vertebral veins.

In examining the peculiar characters of the different vertebræ, it is best to select one from near the centre of each class: thus the 3rd Lumbar, the 6th or 7th Dorsal, and the 4th or 5th Cervical, offer the best examples of the class to which each belongs, for as the cervical vertebræ approach the dorsal, they begin to assume more or less the characters of the latter, and the last dorsal vertebra, upon its under surface, presents the characters of a lumbar vertebra.

FALSE VERTEBRÆ.

Os Sacrum.

Figure, triangular, the base resembling a lumbar vertebra; the apex presenting a small oval surface to articulate with the os coccyx; the sides presenting two surfaces: the superior, large and irregular for articulation with the ilium; the inferior thin for the attachment of the sacro-sciatic ligaments.

Pelvic surface, anterior, smooth, concave from above downwards, traversed by four transverse lines, and presenting on either side of the median line four holes, called *anterior sacral*, for the transmission of the anterior sacral nerves.

Dorsal surface, irregularly convex, rough, presenting in the median line irregular processes of bone (spinous processes), and more externally on either side tubercles of bone analogous to the articular processes of the true vertebræ. On either side of the median line are the *posterior sacral foramina*, for the transmission of the posterior sacral nerves.

Spinal canal, at the base is large, and of a triangular form, runs at the dorsal aspect of the bone, and terminates in a triangular fossa at the apex of the bone, where it is bounded on either side by two tubercles, which are in general prolonged to join the base of the os coccyx.

Os Coccyx.

Figure, triangular, the base articulating with the sacrum.

Anterior surface, smooth, and supports the extremity of the rectum.

Posterior surface, rough, for attachment of ligaments and muscles.

Cornua, are two, placed superiorly, which unite with the last tubercles of the sacrum.

THE THORAX

is formed by the dorsal vertebræ posteriorly, the ribs laterally, and the sternum anteriorly.

The Ribs,

twelve in number, are divided into *seven true* and *five false*; the two lowest of the false being called *abdominal*, or *floating ribs*.

The *true ribs* are each attached to the sternum by separate cartilages.

The *three superior of the false ribs* have their cartilages attached to each other and to the cartilage of the seventh rib.

The *false or floating ribs* have their cartilages free.

Common Characters of a Rib.

The *head*, round, and divided by a ridge into two articular surfaces, which are received into the depressions on the sides of the bodies of the dorsal vertebræ, the ridge affording attachment to an interarticular ligament.

The *neck*, narrow and round; at its union with the shaft is

The *tubercle*, a prominence of bone, with an articular surface looking backwards and downwards to articulate with the transverse process of the vertebræ beneath.

The *angle*, is marked by a rough line, and is the point where the rib makes its great turn to circumscribe the thorax.

The *shaft*,—that portion of the rib which extends from the angle to its sternal end, presents an external smooth convex surface, and an internal concave one; its upper edge being round and smooth, its lower edge thin, and grooved for the intercostal vessels, and its sternal extremity offering an oval pit for the reception of the costal cartilage.

DEVIATIONS.

First Rib.

Has no angle, is very short and flat, a round head with no ridge, and but one articular surface, its extremity being thick and strong; one surface is directed upwards, the other downwards; the superior presenting a ridge for the at-

tachment of the anterior scalenus muscle, which separates two grooves, one for the subclavian artery, the other for the subclavian vein.

Eleventh and Twelfth Ribs,

have neither angle, tubercle, nor groove, are very short, and the head resembles that of the first.

THE STERNUM.

Figure, flat, elongated, broad above, narrower in the centre, and pointed inferiorly.

Anterior surface, is marked by four transverse lines, and is rather convex.

Posterior surface, smooth and concave.

Upper piece, quadrilateral and thick, is concave from side to side upon its upper edge, and presents at each superior angle two semilunar depressions for articulation with the clavicles; its lower edge is united to the second piece; its lateral edges receive on either side the cartilage of the first rib and half that of the second.

Lower piece, long and narrow; receives by five depressions upon its lateral edges, the cartilages of the five inferior true ribs, and by a notch at its superior angle half the cartilage of the second rib, its inferior extremity being long and thin, and ending in a cartilaginous epiphysis, called the

Ensiform cartilage, which is generally bifid, and pierced by a foramen, its direction being variable.

THE WORKING OF THE ANATOMY ACT.

Important as the Anatomy Act was for the purposes of Medical Education, yet its most zealous advocates were quite aware of its imperfections. With these, however, they deemed it expedient to get the Bill passed through the Houses of Parliament, as it was of great im-

portance that the dissection of dead bodies should meet with the sanction of the Legislature, and they trusted to future opportunities of remedying such defects of the Bill as experience might point out, and which the Government could, without outraging the feelings of the community, venture to correct.

One of the most serious evils of which the teachers of Anatomy have had to complain, has not arisen from the framing or spirit of the Bill itself, but from the incompetency or impropriety in the conduct of those individuals who were appointed by the Government to regulate and manage its operations. We allude to the Inspectors of Anatomy in Scotland and Ireland, as well as in England. In each of these countries the grievances which have been complained of by the Anatomical teachers have been of so serious a character that it is now full time this important subject should be brought before the Legislature, in order that some means may be contrived to ensure a just mode for distributing bodies for dissection to the different Schools of Anatomy, as well as to prevent any undue interference of the Inspectors or their deputies. It is now more than two years ago since a remonstrance was sent up to the Home Office, signed by all the respectable Anatomical teachers in Edinburgh, complaining of the gross misconduct of Dr. Craigie, as Inspector of Anatomy; and, notwithstanding every art which was used, and every intrigue which was set on foot to retain him in his office, his misdemeanours were of so deep a die, that the Government considered it imperative that he should be dismissed the public service about the commencement of the last Session.

In Dublin the Anatomy Bill, under the administration of Sir James Murray, was very differently received by the

teachers and students of anatomy than it had been in Edinburgh under the direction of the (Cryssipus) of the North; and this was more praiseworthy upon the part of the Hibernians, when it is remembered the ample supply of subjects, and the very small pecuniary remuneration demanded for them, which, together with the abilities of the lecturers, drew to Dublin so large a concourse of students.

In Cork, however, the working of the bill presented a very different aspect, having an assemblage of features unique and characteristic of "the beautiful city." The students of this southern capital had so long been accustomed to nightly depredations in their visits to the grave, that it was thought a prudent and wise policy not to interrupt their customary avocations by a nonsensical application of the new law, and therefore free permission was given by the liberal Inspector to continue their useful pursuits; and in order to protect them from any interruption, he furnished with the certificates such as are required by the act, only leaving it optional with the student to baptize the subject, and taking care to distinguish the sex.

In London, where procuring bodies for dissection was always a matter attended with great difficulty and enormous expense, the Anatomical Bill was looked upon as a great boon to the students of medicine, and, in consequence, the administration of the new law created much anxiety. The principal duty which devolved upon the Inspector was to distribute the bodies equally to all the different schools, giving each a due proportion according to the number of students. To accomplish this object, a difficulty arose with regard to the parish officers, these having the power of giving the subjects to whom they pleased, or of not

giving them to any one; so that the Inspector, in order to distribute the bodies equally to all the students, was compelled to make some tacit agreement with the parochial authorities.

In making these arrangements, the Inspector was too often frustrated by the sordid intrigues of certain anatomical teachers, who not only exercised their influence to secure for themselves the bodies from particular parishes, but to prevent those subjects which they did not require for their own students, being sent to other schools. With a view of assisting the Inspector to surmount the difficulties which this system had imposed upon him, an association of the teachers of anatomy was formed, with his full approbation, for the purpose of agreeing amongst themselves, to insure an equal distribution of subjects. They agreed that each teacher of anatomy, no matter the number of his pupils, should have one subject at the commencement of his course, which was not to be included in the supply for the students; and that the future supply was to be regulated by the official return of students to the Home Office. However favourable all matters seemed under these circumstances, and with all apparent efforts for the impartial operation of the law, yet but a comparatively small number of the teachers of anatomy have expressed themselves satisfied with the manner in which the Inspector has performed his public duties; for whilst he has allowed schools connected with certain hospitals to have a much larger share of dead bodies than they were legally entitled to, he has on the other hand, not supplied the other schools with the number which they had a right to demand; and in one case, which must be fresh in the recollection of our readers, where repeated remonstrances having had no avail, a direct

application was obliged to be made to the Secretary of State for the Home Department, which, in justice to the noble Lord at the head of that department, received the most prompt and decided attention. It therefore still remains a great desideratum with respect to the Anatomical Bill, not only that the Inspector shall be controlled in the just arrangement in the distribution of subjects, but it would be of great importance, if the legislature would compel the parish authorities to place the subjects under the immediate disposal of the Inspector, so that all jobbing and intrigue with teachers and parish officers might in future be altogether prevented.

REVIEW.

The *Cyclopædia of Practical Surgery*, comprising a Series of original Dissertations on operative Medicine. By an Association of Physicians and Surgeons. Edited by WILLIAM B. COSTELLO, M. D., Member of several Learned Societies both National and Foreign. Part I. April. London, Sherwood & Co.

We hail the first number of this national work, which redounds to the credit of all engaged in its execution. Such a production was a desideratum in British medical literature. The nature of the undertaking is thus explained by the editor:—

In publishing the first number of the "*Cyclopædia of Practical Surgery*," a word of explanation is due to those who, feeling an interest in the success of the work, have remonstrated against the delay that has occurred in issuing it, and which was in some degree unavoidable. It would, doubtless, have been a matter of little difficulty to unite such a number of writers, as would complete the whole work in less time than it has been found necessary to bestow on forming the plan, and developing the original conception of *Cyclopædia*. One moment's reflection will suffice to show, that precipitation would have defeated the great object view, which was to obtain the co-operation of men, whose names alone

would be an authority on the various subjects on which their pens were to be employed. To accomplish this purpose required great exertions, much patience, and, in not a few instances, it was only by the most earnest and persevering exertions, that eminent individuals, reposing on the laurels they had already won in the field of science, could be induced to impose on themselves any fresh task. Nearly three years have been devoted by the editor, to the collection from various languages, of the best sources for reference, to correspondences, and journeys throughout the three kingdoms, for the purpose of personal interviews with distant contributors. The result has been such as to justify the most sanguine anticipations. Eighty-six contributors are enrolled for the production of the *Cyclopædia*, amongst whom will be found some whose reputation is European—some who are honourably known to the profession throughout these realms—and all, or nearly all, already distinguished in the ranks of the profession.

Without such a reunion of talent, it would have been impossible to achieve the object desired, which is to record the present state of surgery in a manner that cannot fail to be useful to the profession at large, as well as creditable to the writers engaged in this important enterprise.

Another motive for retarding the publication, has been the desire expressed by the authors of the earlier articles, to be allowed time sufficient to do justice, as well to their own reputation, as to the importance of a work, which, on all sides, is expected to assume a national character.

The editor had deemed it better to put off the publication of any portion of the *Cyclopædia*, until the time when its maturity was so far established, that the several numbers could be brought out in uninterrupted succession, rather than by a premature issue of some of the earlier numbers, to incur the risk of any momentary interruption in its course, when once begun; and he has now the satisfaction of stating, from an inspection of a large portion of the manuscripts already sent in, that the work, instead of exceeding the proposed number of parts, will in all likelihood fall short of it.

It may, perhaps, become a question in the minds of some, that in a work of so purely surgical a character, as the present, any place should be assigned to the articles composing the obstetric division.

The objections to which their introduction might be deemed liable, have neither been overlooked, nor slighted. After due deliberation it was thought most advisable not to exclude this matter, for the following reasons:—1st, That all the articles of the obstetric division, taken together, will not occupy even a single number of the whole work, and consequently that they might be fairly admitted without defeating the aim of the projectors of the Cyclopædia, which is to impart the fullest information, in the concisest form.—2ndly, The Cyclopædia not being destined exclusively for any particular class of readers, but for the entire profession, it was presumed that a review of the present state of obstetrics, in which the views and experience of the very able men to whom this section of the work is confided, should be interwoven, could not fail to be acceptable to most of our readers.—3rdly, Many of the duties of the obstetrician consist of manipulations so purely surgical, that a sanction seemed to be given for the consideration of the whole subject, if for no better reason than to elude the reproach of being incomplete. These reasons, in our estimation, have had sufficient weight to counterbalance objections which, we acknowledge, have been to us a source of anxiety and doubt. We owe it, however, to the profession, to confine those obstetric articles, which are strictly medical, within very narrow limits.

The articles in the present part are as follow. *Abdomen*, by B. B. Cooper, Esq.; *Abortion*, by Michael Ryan, M.D.; *Abscess*, by W. B. Costello, M.D.; *Acupuncture*, by John Elliotson, M.D.; *Adhesive Plaster*, *Aide*, *Albugo*, *Alse*, and *Alum*, by W. B. Costello, M.D.; *Alveoles*, by T. Bell, Esq., F.R.S.; *Alvine Concretion*, by Alexander Monro, M.D.; *Amaurosis*, by Frederick Tyrrell, Esq.; *Ambulance*, by J. G. Millingen, M.D. The names of the writers are a sufficient guarantee for the excellence of the articles, every one of which is entitled to high commendation, while those on practical subjects are very ably executed.

The Cyclopædia of Practical Surgery will be a work of authority and reference, and is well entitled to encouragement from every medical practitioner. We entirely agree with the editor, as to the necessity of including Obstetric Surgery, and no one in active practice, or acquainted with foreign literature, could sanction the exclusion of such an important section in a Cyclopædia of Sur-

gery. When we look at foreign works of this kind, and look at our own Encyclopædiæ, we find this branch included, and four times more space allotted to it than in the work before us. In our opinion the objection is futile and absurd, and will not obtain with the great body of general practitioners in the United Kingdom.

NORTHERN CIRCUIT.

LIVERPOOL, APRIL 6.

(Nisi Prius Court.)

HENSMAN V. KING.

This was an action to recover the amount of a medical bill.

Mr. SERGEANT ATCHERLEY and Mr. CROMPTON, were for the plaintiff, Mr. CRESSWELL and Mr. WRIGHTMAN for the defendant.

On the part of the plaintiff, his son, who had attended the case with him throughout, and Mr. Dawson, a medical gentleman, well known in this town, who had been twice called into consultation, distinctly denied the existence of any fracture or dislocation, and these witnesses, with several other medical witnesses for the plaintiff, approved of the mode of treatment which the plaintiff applied to the case, and that the disease of the bone which manifested itself, arose from constitutional peculiarity.

Mr. Cresswell addressed the Jury for the defendant, and called witnesses to prove his charge of negligence and ignorance.

Mr. Robert King, son of the defendant said—In the early part of November, 1830, I became lame of my right foot—was able to walk home to my father's house, and afterwards the plaintiff was called in to attend me; on the second day after he examined my leg, and said I had sprained my ankle, and that it would be perhaps a week or two before I got the use of it. He ordered a lineament to be applied—I could walk, but it was rather painful. I used a stick, a few days after the accident, for the purpose of coming down stairs—the crutch was too long, and I fell down stairs upon my lame foot. I was assisted into an adjoining room. The plaintiff was informed of what had happened; but I do not think he made any fresh examination of the foot—but leeches were applied. The inflammation increased afterwards and evidently extended up to the hip in four or five days. During all this time the plaintiff was in regular attendance, and his son also came, and

the latter made an incision in the outer side of the ankle. There was a considerable discharge from the wound, and I was compelled to be constantly in bed. I had to lie on my heel, but at length it became sore, and I occasionally rested my leg on the inner ankle. My mother called the plaintiff's attention to the swollen state of the ankle, and afterwards he was shown the other ankle. I complained very often of the pain I suffered. If I attempted to move my leg the pain was excruciating. Either the plaintiff or his son told me at this time that they thought I should be well in February. When my leg was dressed bandages were put on, and these were begun upwards. An abscess formed in the calf of the leg, and on the 11th of February, a piece of bone came out. My mother said to the plaintiff, who was present, that she thought it dangerous, and he said it might be expected. The second discharge of bone was, I believe, on the 8th of March. This was while the leg was being dressed. The leg varied very little in size. The plaintiff used frequently to measure it. I was recommended to try country air, and went to Bootle. Mr. Dawson, who had been called in some time before, was again called in on the 18th of March, and the wound probed. The same treatment was continued of cold fomentations, &c., but the ointment was a little changed. I recollect a third piece of bone coming away, and my leg being more swelled. Once before I went to Bootle on the 4th of April, 1831, I had attempted to walk on crutches, but found myself worse. On the 8th of April the plaintiff came over to Bootle to see me; I was then much in the same state. He recommended me to point my toe and endeavour to set my foot to the floor, but in trying to do so I felt great pain. On the 14th he came out again to see me, and his son made an incision in the calf, and put lints into it. After that another piece of bone came from the ankle. On the 26th of April the plaintiff was told of my intention to go to Todmorton to see Mr. Taylor, the Whitworth doctor, but he did not approve of it. I did go, and under Mr. Taylor's treatment I was able to walk with a crutch in about a month, and without crutches in about five months. Before the accident my health had been good.

Cross-examined by Sergeant Atcherly. —The first accident was occasioned, I believe, by walking in Everton on the 5th of November. I believe the accident was occasioned by slipping in the street in

Everton, and not by lifting weights in the neighbourhood of this town. Question. —Will you swear that you did not attribute the cause of the injury to lifting weights in the neighbourhood of the Town-hall?—I won't swear that I did not. The plaintiff was told of that as well as of the slip. I will swear that I did not complain of the left leg, and that leeches were not applied to it. The plaintiff was not specially sent for, but happening to be attending another member of the family, he was shown my leg; but I don't remember that I had much pain till after the fall down stairs on the third day. The plaintiff and his son attended me from day to day. I kept a diary from the 6th of March, 1831. I have a tolerable use of my leg now. There is a discharge from my leg still. Mr. Taylor attends me for it. He was last with me about three months ago. I have perhaps been twenty times at Todmorton to see Mr. Taylor. I am not now taking any medicine, but applying salve in the daily dressing. I was able to walk in the street in October, 1831, without crutches. I never had any swelling in the glands of the neck. I have one sister. She had never any swelling of the kind either. My brother had an abscess in the shoulder about three years previous to my accident. The plaintiff came twice a day to see me, and dressed my leg also once or twice a day. I thanked him for his attendance, and thought he had been very kind to me.

Re-examined.—My opinion altered after I benefitted by Mr. Taylor. My brother was young at school when he had the abscess. He had hurt himself at school, but I was not present at the time.

Mr. James Taylor.—I am a surgeon, and am a descendant of the family that first became celebrated at Whitworth. I became a member of the College of Surgeons in 1825, and settled at Todmorton in 1829. I have a brother who is also a surgeon, and who was with me in consequence of illness at the time Mr. and Mrs. King brought their son, the last witness, to me in 1831. I found the sole of his foot turned outwards and downwards. The inner ankle projected very much, and the leg was much swelled, and hard almost as a board. I was quite satisfied of a fracture, and of the kind of fracture, from the position of the foot, before I touched it. I made no inquiry at the time about the treatment. The defendant determined to leave his son with me, as I told him I could not otherwise do any-

thing for him. I thought the case would be tedious. There was a great discharge from two wounds in the leg. I never saw any appearance of scrofula, nor had I any suspicion. The treatment of the leg previously would have accounted for the appearances presented, and for the exfoliation of the bone. I gave him very little medicine—not, perhaps, half a dozen bottles all the time he was with me. He was under my care about half a year when he left first. I remember his coming back to me in 1833. The discharge was still great. I made an examination by laying the wounds more extensively bare when he first came, and then found that there was a fracture of the bone, and which accounted for the discharge. I have seen him about three months ago, and there is still a slight discharge which is owing to the remaining portion of diseased bone. During all the time I have attended him I have never seen any symptom of scrofula.

Cross-examined.—I have no doubt at all that the patient had false fracture. I could judge from the appearance of the limb that it had been of at least three months standing. I should think that any surgeon could tell by the sight or the touch whether there was a dislocation of the bone. I should think a man could not walk with false fracture. A mere fracture would not produce diseased bone unless the limb should remain unreduced.—Did you ever see a case of dislocation of the ankle, even without being reduced, create abscess? No: but if the motion of the ends of the bone creates inflammation, an abscess may be the result. If the matter in the abscess was allowed to lie upon the bone it would create a diseased bone. The disease in the bone did not arise from any peculiarity of constitution. The medicine I gave was principally of an aperient kind. The limb is not entirely reduced, and never will be. There has been no disease in the joint of the ankle. He cannot walk yet safely without the support of the boot he wears. With the exception of dressing the leg, and some aperient medicine, I used no other means with the leg than the laced boot.

Other witnesses were called principally to prove that the patient had no constitutional complaint.

The learned Judge, in summing up, said that if the plaintiff had ever been mistaken in his treatment, still, if the Jury thought that he had used ordinary skill and attention, they must find their verdict in his favour.

Verdict for the plaintiff for the amount claimed, 49*l.* odd.

The trial lasted all day. The court was crowded.

THE EDGEWARE ROAD MURDER.

CENTRAL CRIMINAL COURT

Tuesday, April 11th, 1837.

Second day,

Conviction of both Prisoners.

MEDICAL EVIDENCE.

The following account of the medical evidence, in the case of the King *v* Greenacre and Gale, will be read with interest by medical practitioners. It shows the importance of studying medical jurisprudence and of discriminating between contusions and wounds inflicted before and after death.

The identification of the dismembered body of the unfortunate deceased, (her head, trunk, and feet having been scattered in remote parts) solely rested on medical evidence; and that testimony was satisfactory and conclusive. The evidence of Mr. Girdwood proves him to be a highly scientific and well informed medical practitioner. It also shows that he is well acquainted with the rules of medical evidence. Witness of his information have nothing to fear from advocates in courts of justice. Were the majority of medical men equally well informed, and they decidedly ought to be so, when human life is at stake, we should not so frequently witness the lamentable exposures of medical ignorance in criminal as well as civil proceedings.

The importance of medical evidence is considered so great in Continental Europe, that certain eminent medical men, who have entirely devoted themselves to medical jurisprudence are only admitted as witnesses. This is a most wise ordination, for it will be found on inquiry of the most distinguished physicians and surgeons that they are totally unacquainted with the minutæ of many physiological, pathological, and toxicological points which may become subjects of inquiry in courts of justice. This proves the necessity of studying medical jurisprudence which explains such points according to the received opinions of the profession.

Mr. John Birtwhistle was then sworn and examined by Mr. Adolphus as follows:—

Witness.—I am a surgeon, and reside

in Mile-end-road. On the 6th of January I saw a human head in the dead-house at Stepney. I examined it closely on the following day, the 7th of January. It was then exactly in the same state. I found that it had received a blow on the right eye, the coats of which were injured, and the humours consequently let out. There was a blackness around the eye from the rupture of the smaller vessels. It was what I should call a tremendous black eye, which appearance was caused in my opinion before death. After the death of the body a blow on the eye would not have produced that effect. The eye itself remained in the head devoid of its humours. There was a crescent-shaped laceration on the cheek, and the lower jaw was fractured. The former, in my opinion, was produced by incision, and the latter was produced by a crush or jam. Both appearances, I think, took place after death. There was also a wound on the top of the head, apparently produced by a blow. Upon examining the neck, I found that the cervical vertebræ had been sawn through. A saw of this description (the one found in Greenacre's box) would have been likely to have done it. I have since compared this saw with the bones of the neck, and found that it exactly fitted. After I had examined the head and neck in the manner described, I put it into a small hamper, tied it up, and sealed it with my own seal. I then gave it to two policemen, who took it to the work-house at Paddington, where I saw the hamper on the following morning with my seal unbroken. I subsequently examined the head in company with Mr. Girdwood, the surgeon, who agreed in opinion with me, that the wounds on the face and the injury to the head were produced after death, and that to the eye was produced before death. We then opened the head, and found an internal wound on the back part, which did not appear externally. I think from its appearance that this internal wound was produced before death. My opinion is, that if a blow had been struck on the eye, the fall from the force of that blow would have produced the wound on the back part of the head. It appeared to me that the throat had been cut before death. The head was entirely free from blood, which I think would not be the case if the throat had been cut after death.

Cross-examined by Mr. Price.—I never witnessed a case in which the head was exhausted of blood by means of a broken neck. The blood will flow while the body

is still warm. Warmth might remain in the body for an hour or two after death. I have been a surgeon since 1827, and have examined many bodies recently, but not immediately after death. Mr. Girdwood attended the latter examinations of the head at Paddington workhouse. I consider him a very clever surgeon. There is a distinction between a bruise and a contusion. The latter might not produce any blood upon the surface, but a bruise always does. I did not examine the neck of the deceased myself, but I was present on the 8th of January, during the whole examination of the head. The bones of the neck were taken out by Mr. Girdwood, leaving the flesh only. There was an observation made in dissecting the neck, with regard to the retraction of the muscles. After the column of the neck had been separated from the neck, Mr. Girdwood took possession of it, and I believe has it now. From the jagged appearance of the vertebræ of the neck, I should say that it must have been sawn through, and not cut with a knife. The saw produced would have done it. I did not examine the spinal marrow. The internal wound on the back of the head inclined towards the left side. I cannot say whether or not that blow might have caused a suffusion of blood in the head. It might or might not.

Mr. G. S. Girdwood, examined by Mr. Bodkin.—I have practised as a surgeon for twelve years, and am surgeon to the parish of Paddington. On Sunday, the 8th of January, I examined a human head, in the workhouse, in company with Mr. Birtwhistle, the last witness, and some other gentlemen. The result of all the examinations of the body of the deceased were published in the newspapers on the following day, the 9th of January. On Sunday, the 8th, I first saw the head at Mile-end workhouse, and made a minute examination of it on the following day, when it was brought to Paddington workhouse. The head had the appearance of being that of a female. The nose had a slight twist on the right side. There were several wounds and bruises. There was a large wound on the left cheek, in the shape of a crescent, commencing under the left eye and terminating within about an inch from the mouth. That was an incised wound, and merely superficial. In my judgment it was inflicted after death. There was under the wound just described a large contused wound, producing a fracture of the jaw, inflicted after death. On the other side of the

face there was another contused wound at the right angle of the jaw, and there too the bone was broken. On the same side of the jaw there was another contused wound, opening right through into the mouth. Both the latter wounds were, I believe, produced after death. Several of the teeth of the upper jaw were forced out, and the tongue was cut between them. This occurred also after death. The right eye had received a blow. There was a wound in the eye itself above the pupil, which had entered into the eye and occasioned the escape of the humours. About and around the eye there was an ecchymosis surrounding the eye, commonly called a black eye. Within the area of this bruise there were three small superficial wounds—one was external to the orbit of the eye; the other was superior to the orbit of the eye, and the third was on the side of the nose, and exposed the bone of the nose. I believe the wound of the eye and the discolouration around it to have been produced before death, and the three marks I have mentioned after death. The blow given would imply great force, from the eye being knocked out. The blow might have been produced by a fist. The blow produced no abrasion of the skin, from which I should say that the blow must have been a dull one, but it is impossible for me to say whether the blow was inflicted with the fist or with an instrument. It certainly would have deprived the party so struck of sense for a time. The length of time would depend entirely upon the nervous system. The effect of such a blow upon a female would very probably have deprived her of sense so as to give an opportunity for further injury. The blow being struck in front, if any injury to the back of the head occurred at the same time it would have increased the insensibility or stupor. On the crown of the head there was a large contused wound, at one end of which there were two contusions, but these and the wound itself took place after death. The scalp of the skull was cut crossways. The witness proceeded to describe the appearances which were exhibited in the interior of the skull. The red appearance of the *dura mater* indicated a disturbance within, produced by the injury in front by some opposing or resisting body. The internal injuries at the back of the head must have been occasioned by that part coming in contact with some hard substance. The injuries to the eye could not have been caused by a blow struck on the back part of the head, whether that

blow was occasioned by a fall or otherwise. I afterwards proceeded to examine the neck, and found that the fifth bone had been sawn, but not quite through, from front to back. The remainder appeared to have been broken off. There was no appearance of dislocation of the neck. The fleshy part appeared to have been cut with a sharp instrument such as this (the knife found in the prisoner Greenacre's box.) The muscles of the neck were retracted. They would continue so while life existed. In the case of a person meeting a sudden death that appearance of the muscles would continue for some hours, but the retracting power would continue to grow less every hour. I found all the large blood-vessels of the head quite empty. Independently of the separation of the neck from the head, there were superficial cuts around the neck. The principal cuts were not continuous, in consequence of the muscles being placed lower down in the neck, so that the incision which cut through the windpipe is full two inches lower than the first incision. The cut through the windpipe also cut through the carotid arteries, and it is on a level with the division of the gullet. The first superficial cut left a flap of skin hanging over, and adhering to the body.

By Lord Chief Justice Tindal.—The cut above was the first cut, and all the cuts in the neck must have been inflicted during life, or very shortly after death. The suggestion which occurred to my mind by all these appearances was that if the blow which knocked out the eye had not been sufficient to produce death of itself, the cutting of the throat would of course have at once occasioned death.

Cross-examined by Mr. Price.—A bruise and contusion I should say are synonymous terms. Ecchymosis might be produced either by one or other, before death, but not after. A blow at the back of the head would produce a lodgment of blood within the cranium, but not to any extent; I never knew a blow on the back of the head produce an injury on the opposite side of the head, and it could not occasion a lodgment of blood in the eye. It is impossible to produce all the phenomena of ecchymosis on a cold and dead body. I am the author of a reported inspection of the head of a female published in the *Medical Gazette*. Blood will flow from a vessel divided after death for several hours. I think an experiment took place in which blood flowed for sixteen hours after death, but I speak from memory and may not be quite cor-

rect; I cannot say how long the head would take to empty itself of blood after death. The separation of the head from the body, in this instance, could not have been done by a professional man as an experiment. I did not observe any injury to the spinal marrow, judging from the external bones. I did not examine the marrow itself, but there might have been an injury to the spinal cord which would cause death, without producing any external appearance. An injury to the spinal marrow might produce instant death, but it is not very likely that such an instance could occur without leaving some slight trace of the injury externally. The fact of the head having remained for some days in the water would not have removed the appearance of external injury. To ascertain if a person died from an injury to the spinal marrow, it would be necessary to examine the spinal marrow itself. A blow externally might so injure the spinal marrow as to occasion death, but I cannot imagine that it would do so without leaving some appearance in the spine. I cannot imagine a case in which the sudden muscular action of the neck would occasion death unless it caused at the same time an injury to the spinal marrow.

By Lord Chief Justice Tindal.—If such an injury had occurred to the deceased, I must have detected it during my examination and dissection of the neck of the deceased.

By Mr. Price.—All sorts of accidents producing injury to a vital part would necessarily produce death. If the part of the spine which I did not examine had received an injury it might have caused sudden death. I examined the body of the deceased on the 29th of January, and from the appearance of the cut incisions I should say that the mutilation must have taken place immediately after death, both from the bloodless state of the body itself and other circumstances. The stomach was removed from the body and looked into. There was no injury to the coats. It contained undigested food, and I think it had a spirituous smell, but I did not observe what description of spirit. My examination of the stomach was very cursory, and merely with a view to ascertain whether any injury existed in that part which could have caused death. The deceased was about five feet six inches and a half high. She was, as far as outward appearances went, a well formed woman, stout, and strong, and, as far as I could judge, in perfect health at the time of her death.

Re-examined by Mr. Bodkin.—I am quite certain that the injury to the eye was inflicted during life. There was a puffiness and thickening around the eye which could not have taken place after death, independently of the discolouration. The appearance in the orbit of the eye would have been produced by a violent blow. Looking at the whole appearance of the body, and other members of the deceased, I find that there is in the first instance a severe blow in the eye, and looking at that injury, and at the whole group of facts and appearances, I should say that they were sufficient to cause death.

Mr. Bodkin.—In your opinion was the blow at the back of the head the consequence of the blow upon the eye?

Witness.—Certainly.

Dr. James Hunter Lane, examined by Mr. Clarkson.—I am a physician and lecturer on chymistry. I examined the stomach of the deceased, in company with Mr. Guy, a medical student. On examination, I found a quantity of meat, which I supposed to be pork or beef, together with potatoes and pastry, and the whole of the fluid had a spirituous smell. The stomach was healthy and exhibited a slight redness, which usually denotes a good digestion. With regard to the spirituous smell, I came to the conclusion that it was neither whiskey nor rum, and that it was gin, to the best of my belief. I satisfied myself of that by a chymical test. The quantity of spirits, I should say, was not sufficient to cause intoxication. The progress of digestion was about half completed. I also came to the conclusion, from the absence of all morbid appearances, that the deceased could not have died from taking poison, and I should say that her death was sudden, from the fact of the food being undigested in the stomach, and that no disease appeared there.

By Lord Chief Justice Tindal.—There was no appearance of tea in the stomach.

Mr. Guy proved that he took the stomach from Mr. Girdwood, and carried it just as he received it to Dr. Lane.

Dr. Lane, cross-examined by Mr. Price.—A quantity of tea taken into the stomach would have covered the smell of gin, but not of whiskey or rum. The presumption is, that no portion of the contents of the stomach had been drawn off by evacuation. I examined the contents ten days after the 24th of December. A sufficient interval had elapsed to allow a portion of the odour to escape, but not wholly so.

Mr. Adolphus.—My Lord, that is the case on the part of the prosecution.

THOUGHT.

Thought not Substantial—Its True Nature Explained—Stimulus to Thought—Difference between Mind and Soul—Mind of a Dog—Proof of a Soul in Man—Ancient Opinion of Mind—Mind not Material, but Substantial—Authors who support that View—Faculty of Thinking the Result of Organization—Materialism—Authors who support that Doctrine—Seat of Thought—Antiquity of the Opinion, that different Parts of the Brain belong to different Thoughts—Seat of the Passions in the Thoracic and Abdominal Viscera—Natural Language of Emotion—Argumentum ad Percussionem—Progressive Development of the Brain—Decussation of the Corpora Pyramidalia—Non-Decussation of the Corpora Olivaria—Proportion of the Cerebellum to the Cerebrum in different Animals—Formation of the Corpus Dentatum and Arbor Vitæ—Cerebellum of Birds—Cerebral Convulsions wanting in Idiots—Errors in Gall's System—Proper Seat of the Sensorium—Charles Bell on the Structure of the Skull—Analogy with Gothic Architecture and a Soldier's Helmet—Formation of the Squamous Suture—Unity of Organization in the Skull—Relative Height of the Brain and the Body in different Animals—Norma Verticalis of Blumenbach—Varieties of the Human Race—Caucasian, Mongolian, Ethiopian, American, and Malay varieties—Chinese, Egyptians, Hindoos, Greeks, Javanese, New Hollanders, and Esquimaux—Innate Ideas—Plato and Aristotle—Opinions of Malebranche, Fenelon, Descartes, and Leibniz.

bnitz—Bacon, Locke, and Kant on Acquired Ideas—The difference between Attention, Comparison, Judgment, Reason, Memory, and Recollection—Foundation of Dr. Gall's System—Explanation of Monomania—Elementary and Compound Thoughts—Passions, Sentiments, and Talents—Phrenology—Sexual Love—Love of Offspring and Country—Attachment—Contention—Destruction—Construction—Secretiveness—Cunning—Pride—Love of Praise—Caution.

Thought is not substantial, any more than life is. It is the faculty of thinking in action. In this view of the matter mind is as much a property of one part of the corporeal system as irritability is of another part. The only stimulus to thought is sensation. The mind is not the soul; for a dog has evidently all the faculties of the mind, though not possessed of a soul. The proof of the existence of the human soul rests on revelation. We may not understand how the mind exists; but we know nothing of a blade of grass apart from its properties, and even if we knew all about it, that would afford us no ground for concluding that nothing can exist which we do not comprehend.

By all the ancient philosophers, the mind, like life, was considered to be a substance. The following authors think the mind is not material, but a substance added to matter:—Bacon, Descartes, Malebranche, Cudworth, Locke, Condillac, Price, Reid, Stewart, Brown, &c. I do not look upon thought as the result of organization, but I conceive the faculty of thinking is. The writers I have mentioned think the mind is a subtle substance, known by its properties, which are different from those of matter. Those who think that irritability is the result of organization consider that the faculty of thinking is so likewise; and the following authors are of the same opinion:

Gossandi, Hobbes, Berkeley, Priestly, Leibnitz, Buffon, Darwin, Hume, Kant, Gall, Georget, &c. These are really materialists; but the extravagance of many advocates of that side of the question, have caused the name to be considered a stigma.

Thought was always considered to have its seat in the brain; and different seats were ascribed to different thoughts by Galen, the Arabians, Albert-le-Gand, De Martigny, Willis, Vieussens, Boerhaave, Van Swieten, Haller, Soemmering, Prochaska, Cuvier, Gall, &c. The passions were placed in the thoracic and abdominal viscera by the sacred writers, the early poets, and by Hippocrates, Plato, Galen, Bordeu, Buffon, Bichat, Cabanis, Riel, &c. The argumentum ad percussionem was resorted to by different authors, as when people strike their breasts to represent emotion. Willis observed that the fore part of the brain was the seat of thought; for a man puts his hand to his forehead when he feels at a loss. Gall says the occiput is the seat of the sexual feelings; for lascivious girls, if highly excited, clap their hands to the back of the neck.

The brain progressively advances to perfection, through the several grades of worms, insects, osseous fishes, cartilaginous fishes, frogs, tortoises, serpents, lizards, birds, the rodentia, the ruminantia, the solidungulæ, the feræ, the quadrumana, and man. The decussation of the corpora pyramidalia is denied by Haller, Vicq. d'Azyr, Munro, Bichat, Chaussier, Gordon, and others. It is asserted by Aræteus, Misticelli, Petit, Santorini, Winslow, Lieutaud, Soemmering, Gall, Cuvier, Tiedeman, and others. Meckel says the decussation is so evident, that it is wonderful it should ever have been doubted. The corpora olivaria do not decussate, resembling the optic nerves in this respect. The decussation of the posterior columns of the spinal marrow, which are expanded in the cerebellum, has not been detected, owing to the plexiform arrangements of their fibres; but we must presume their decussation, in order to account for the effects of an injury of the cerebellum, being on the opposite side of the body.

The following is the proportion which, in different animals, the cerebellum bears to the whole mass of the brain. 1. In the horse, one-seventh. 2. In the sheep, one-fifth. 3. In the beaver, one-third. 4. In the mouse, one-half. In the crura cerebelli, the grey matter is internal,

forming the corpus dentatum; but in the cerebellum itself, it is external, forming the arbor vitæ. In birds the cerebellum is not divided into lobes, but has transverse layers, analogous to the appendix vermiformis. There is no division of the cerebellum, so as to form lobes, until we come to the mammalia. The crura cerebri are always in contact; but the crura cerebelli have the fourth ventricle between them. The first parts which grow from the crura cerebri are the thalami nervorum opticorum, (the posterior tubercles of Dr. Gall's system,) with the third ventricle between them. In all animals in which they are found, below the mammalia, they are hollow, and have no commissura mollis. The corpora quadrigemina are represented by some as the terminations of the respiratory columnis. Between the testes is the aqueduct of Sylvius.

After forming the optic thalami, and the corpora striata, the crura cerebri are expanded into the lobes of the cerebrum; the anterior lobes being formed first. In the fish there are no hemispheres, the brain consisting of the optic thalami, and the corpora quadrigemina. Sometimes in idiots the posterior lobes of the cerebrum are wanting; in which case there are no posterior cornua of the lateral ventricles. The corpus callosum is first seen about the fourth or fifth month. The hippocampus minor is found in apes. The ventricles are now often called the figurate, or white surface of the brain; while the other is called the grey, or lobulated surface. As all the ventricles communicate with each other, and open externally at the foramen of Bichat, they may be regarded as the internal surface of the brain. This surface has the figure of an irregular cross. The rudiments of the cerebral convolutions are perceived about the fifth month of foetal life; but they are not very evident till the seventh. In idiots they are said to be sometimes wanting altogether.

The recurrent nerves of the cerebellum, as they are called by Dr. Gall, are said by him to meet in the tuber annulare; while those of the cerebrum meet in the commissures. Tiedeman objects to this, that the commissures are seen before the convolutions; but this is quite consistent with what is seen in the organization of other parts. Gall was wrong in supposing the fornix was a commissure. He was likewise unfortunate in calling the grey matter the matrix of the white; for the latter is formed first. The sensorium is,

properly speaking, the posterior columns of the spinal marrow. In man, the brain is about the twentieth part of the weight of the body. There is a bag of arachnoid hanging out of the fourth ventricle. Magendie thinks the cerebro-spinal fluid between the arachnoid and pia mater exercises a salutary pressure.

Charles Bell thinks the thick part of the parietal bones is designed to give support to the skull; just as pinnacles are erected, in Gothic architecture, to counteract by their weight the tendency of the arches to spur outward. The dura mater, and the outer table of the skull, act in the same way as the leather lining of a helmet, and the horse-hair with which it is provided outside; they prevent vibration. He likewise observes that the inner table of the skull, which is brittle, is not jointed with sutures, but with cellular tissue, which serves the same purpose as lead between the junctions of a marble column. The squamous suture, he thinks, is analogous to the chains which surround a dome, like that of St. Paul's. Munro accounts for the formation of this suture by supposing that the ends of the bones are made so thin by the pressure of the muscles and the brain, that they overlap.

In animals below the class of birds, the sphenoid consists of two pieces, and the foramen magnum is placed far behind; so that in the resemblance between the bones of the skull and spinal vertebrae, is very plain. But in birds, the sphenoid bone is not divided, and the foramen magnum is almost in the middle of the skull. In them, likewise, the brain occupies the whole of the skull, which is not the case with reptiles and fishes. In some cases of hydrocephalus the ossa triquetra are so enlarged that they look like additional parietal bones; and if the temporal bones be looked upon as the rudiment of a fourth cranial vertebra, the ossa triquetra are the rudiments of its ring. In the mammalia alone the ethmoid bone transmits the olfactory nerve. It would be curious to ascertain whether, in those animals in which one side of the brain is larger than the other, as the phœter, &c., one side of the body is more powerful than the other. I think it would be found to be the case.

The following is the relative proportion which the cerebellum bears to the cerebrum. 1. The human fœtus, one to twelve. 2. The human adult, one to eight. 3. The horse, one to seven. 4. The sheep, one to five. 5. The beaver, one

to three. 6. The mouse, one to two. The following is a table of the proportion which the brain bears to the body, in various animals. 1. Man, one to twenty. 2. The ape, one to twenty-five. 3. The rat, one to thirty-two. 4. The sheep, one to thirty-five. 5. The cat, one to thirty-eight. 6. The pigeon, one to ninety-one. 7. The eagle, one to a hundred and sixty. 8. The salamander, one to three hundred and eighty. 9. The elephant, one to five hundred. 10. The pike, one to a thousand three hundred and five. 11. The tortoise, one to two thousand two hundred and forty. In the lowest animal in which it has been estimated the proportion is only as one to thirty-seven thousand four hundred and forty.

Monro's plan of estimating the size of the brain is perhaps the best. It consists of a frame-work, into which the skull is put, and its dimensions noted. It should be marked out into different portions, and figured, that we may know what particular parts project and recede. Blumenbach makes his five species according to the norma verticalis, taking the Caucasian as the standard of perfection. The fine examples he gives are the portraits of the best specimens he could meet with of the different races. These races are the following. 1. Caucasian. 2. Mongolian. 3. Ethiopian. 4. American. 5. Maylayan. The Chinese and Esquimaux belong to the Mongolian variety, in which the eyelids are generally oblique; while in the Ethiopian variety, they slope in a contrary direction. The American variety is between the Caucasian and the Mongolian. The Egyptians, Hindoos, and Greeks belong to the Caucasian variety; the Javanese and New Hollanders to the Malay. There is some truth, but much fancy, in this arrangement.

Plato thought ideas were innate, and that every thought was in the mind originally, and was only called into exercise by the object to which it related. Aristotle took up an opposite doctrine. The former attached too much to the susceptibility, which is one condition; the latter attached too much to the stimulus, which is the other condition. Diogenes said he had no idea of a table, or a goblet, before he saw them. Ideas are only the thinking principle in action, and are no more substantial than combustion is. Malebranche said that ideas came from God; and Fenelon, that they are God himself. Both proceed on the

identity of the soul and the mind. Berkeley and others have doubted their own existence; and that is, in fact, a necessary corollary, if the doctrine of innate ideas be followed out. They said we could form ideas of colour and hardness, even if we were not acquainted with substances which possess those properties. That, however, is not the case. But if the mind were merely a mirror, reflecting external objects, as Aristotle said it was, how could different persons betray different dispositions in the same circumstances? What are the "abstract ideas" of Plato and the "mirror" of Aristotle, but the capability of being acted on by stimuli. The advocates of innate ideas are Plato, Descartes, Malebranche, Bossuet, Fenelon, Leibnitz, &c. The advocates of acquired ideas are Aristotle, Bacon, Locke, Condillac, Buffon, &c. Bonneti, Kant, and Gall have given the best views of the nature of thought.

Sensibility being less in females and children, thought, which is built on sensibility, is less also. This holds true altogether in children; but only in some branches of thought and feeling in females. As different parts of the spinal marrow are capable of receiving different impressions from the several senses, so different parts of the brain are probably adapted to different impressions, which thus excite different thoughts. Attention is said to be the mere perception of a sensation. Comparison is the perception of a resemblance or of a difference. Judgment pronounces on the relations of several sensations. Then there are reason, memory, and recollection; the latter being the remembrance of a sensation previously remembered. Each sense acts independently of the others; but these modes of thought cannot act independently. Kant admits twenty-five different kinds of thought. His enumeration proves how arbitrary arrangements are. Physical properties are easily determined; but where can we draw distinctions in mental phenomena? It is evident that ideas of "time" and "place," which Kant places first, are not elementary; for they cannot be appreciated by one form of thought.

Dr. Gall founded his system, not on the difference of thoughts themselves in their own nature, but on the observed mode of action in different instances. Kant's is the synthetic mode: Gall's the analytic. He makes about thirty-three different kinds of thought. The first nine are the feelings; the next nine the

sentiments; and the last fifteen the talents. The exercise of any one of these requires that of many others, as wit and imagination, for instance. Many of them are modifications of others, as the "love of offspring," and the "love of country." Is there any real difference between "pride" and the "love of praise," or between the "memory of thoughts" and the "memory of words?" Again, "theft" and "cunning" both arise from "love of self."

It is quite a mistake to suppose, that the doctrine of different parts of the brain, being appropriated to different forms of thought, originated with Dr. Gall. Many of the most eminent philosophers have supported that opinion; but this by no means obliges us to believe that he has been right in fixing on the exact seat of each particular form of thought; or that these seats, if determined in the brain, are obvious through the skull. It may or may not be so; but it does not necessarily follow. If the whole brain presided over all the modes of thought, a man of education might be raised to the highest station as a poet, or in any other walk of literature or science. Another objection is, that monomania could not be explained on that hypothesis. I doubt not every part of the brain ministers to different elementary forms of thought; but, at the same time, I feel quite satisfied we are ignorant what those forms are. Perhaps almost all the thoughts which are considered to be elementary, are in reality compound; as is the case with those compound bodies, in physical science, which a few years ago were looked upon as elementary. But though we cannot say of any particular propensity, that it is seated in any one particular part of the brain;—for the propensity may be compound, and may therefore require the concurrence of other parts of the brain for its production;—yet we may be warranted by experience in saying, that in proportion to the size of that particular part of the brain, will be the force of that particular propensity; for it is probable that the part of the brain in question, furnishes the chief, though not the sole element of the propensity. Every observer must admit, for instance, that in proportion to the size of the brain, are the strength of the bad passions; and these passions are first manifested, because the brain grows from the base. Again, the talents are developed before the sentiments.

In the organs of the senses, and all the

other organs of the body, *cæteris paribus*, size indicates power. Hufeland says, that organology is undoubtedly true; but that organoscopy is doubtful. Below the class of birds, the brain does not correspond to the skull; and even in birds, the air in the diploe, between the two tables of the skull, interferes with any judgment we may form of the exact shape of the brain. This want of correspondence between the two tables of the skull applies with less force to the human subject; but still there are often prominences on the brain, which are not corresponded to by projections on the skull; the inner table of the skull being alone affected. It is said, however, that there generally is a development of the skull over such a part of the brain. But phrenology was established on the relation which might be observed between the propensities and the form of the skull, not of the brain, which cannot be reached before death. I think the question must be settled by experience. It is not to be proved that phrenology must be true or false; but that it is true or false.

We shall now briefly glance at the organs in detail.

1. *Sexual Love*.—This organ comprises the cerebellum. It was first established by Dr. Gall, in the head of a young widow, who was the subject of nymphomania. He found a similar correspondence between a large size of this organ, and the manifestation of strong sexual propensities, in other animals as well as man. When there is inflammation of the cerebellum, priapism is an attendant symptom. The organ is large in the celebrated Raphael, and in the Farnese Hercules. The notorious Mrs. M'Innis has quite a "bull-neck."

2. *Love of Offspring*.—This organ is placed at the base of the posterior lobes of the cerebrum. It is larger in the females of all animals than the males. In those persons who are guilty of infanticide, this organ is generally found small; as well as in those animals which quickly leave their young to shift for themselves. Those females in whom it is particularly large are very desirous of having a family.

3. *Love of Country*.—Mr. Combe does not believe in this organ.

4. *Attachment*.—Situated at the lateral part of the posterior lobes of the cerebrum. It is larger in females than males; and hence, the former, from a very early period of life, manifest a fondness for pets. It is large in Mrs. M'Innis.

5. *Contention*.—This is placed behind the ear. It is larger in males than females; and, when well developed, gives the "thumping gait, and determined voice." Its action is often violent in drunkenness, producing quarrels among companions, who, nevertheless, are very good friends. Gall first observed it in prize-fighters. It is large in Bruce, of Scotland, M'Innis, the Charib skull, and Haggart, who was hanged for murder. It is also large in gladiators.

6. *Destruction*.—Placed above the ears. It is especially large in the carnivora. Its action is not restricted to murder; but shows its influence in the destruction of everything which comes in the way, and in cursing and swearing.

7. *Construction*.—Very large in sculptors. In Michael Angelo it is enormous. It is situated at the temples, and designates a skilful workman; and Mr. Mill was guided by the size of this part in hiring his workmen. It is large in all painters; Wilkie and Haydon, for example. The beaver has this organ very much developed.

8. *Secretiveness*.—Placed above and before the organ of destruction. It gives a rounded juvenile form to the head. Some persons who have stolen articles under its influence, afterwards give them up, for the propensity only leads to the exercise of ingenuity in taking them.

9. *Cunning*.—Situated behind secretiveness. It is said to give the head a tendency to drop forward, and to one side. It is much exercised by artists and actors; and sometimes enables a murderer to conceal his crimes.

10. *Pride*.—This is the first of the sentiments. Those we have previously examined are called propensities. The organ of pride is situated on the top of the head, at the part which first becomes bald. It is larger in males and the English, than in females and the French. It is large in the Hindoo and the American Indian, and likewise in the criminal Haggart. Under the influence of this organ, the head is thrown back.

11. *Love of Praise*.—Inspired by this organ, a man consults the opinion of the world, which a proud man does not. It is large in the French, in women generally, and in the Scottish Bruce, but not in Haggart.

12. *Caution*.—The locality of this organ is at the point of ossification of the parietal bones. It is more developed in children than adults, and in females than males. Hence female animals are seldom

caught in a trap. It is large in deer, owls, and nocturnal animals in general. It is likewise well developed in Bruce, and in Egyptian mummies.

ORATION

DELIVERED BEFORE THE MEMBERS
OF THE

ROYAL MEDICAL SOCIETY
OF EDINBURGH,

AT THE

CELEBRATION OF THEIR CENTENARY,

February 17, 1837.

By W. B. CARPENTER,

Senior President of the Society; Member of the Royal College of Surgeons, London; and President of the Royal Physical Society, Edinburgh.

(Continued from p. 45, No. 2.)

I trust that I have succeeded, Gentlemen, in leading you to the view which I have myself been led to entertain, that the formation of the Medical Society of Edinburgh constitutes a most important era in the history of our science. And this I maintain, not only on account of its subsequent contributions to its advancement, but because it created a new field for the exercise of the intellect at the age of its greatest vigour and activity. The Societies which had previously been formed for the improvement of philosophy, had not so much in view the discussion of theories, as the collection of facts, and the performance of experiments. These were the objects of the Lyncean Society of Florence, the earliest institution of the kind, which afterwards merged into the celebrated Academy of that city; and the Royal Society of London, framed upon the plan and carrying into effect the principles of Bacon, had similar ends in view. "For the improvement of theories," says Sir C. Wren in one of his communications to it, "we need be least solicitous; it is a work which will insensibly grow on us, if we be always doing something in experiments. This is rather our task, and in many things we must be content to plant crabstocks for posterity to graft on."

The Medical Society of Edinburgh aspired to bolder objects. Unawed by the authority of their teachers, unfettered by the dogmatic spirit which was still too prevalent in the schools, its members

dared to think for themselves and the overthrow of the doctrines of Boerhaave, and the establishment of the more correct principles of Hoffman, first in this University, and subsequently throughout the British empire, were among the earliest effects of that freedom of thought and expression, which this Society was the first to exemplify, and which still constitutes its leading principle. Like the compass of the mariner, it opens the way to regions of unexplored magnificence; no longer restrained within the narrow and well known channel of received opinions, the inquirer after truth can now stand boldly out into the wide and trackless ocean, confident in the security of the haven which will be his resting place, and in the richness of the mine which is to reward his exertions.

The merit of Hoffman consisted not only in the important additions which he made to our knowledge of the laws of the animal economy, especially with regard to the distinct nature of the vital properties and the influence of the nervous system, but also in his having pointed out the track by the pursuit of which still further advancement might be obtained. The interesting inquiry which he originated was most successfully prosecuted by Haller and Cullen; and although greatly modified and improved by them and their followers, his doctrines may be regarded as the germ of the systems of Physiology and Pathology which are now universally received. It is well known that Dr. Cullen on his succession to a medical chair in this University, was the first who disputed the authority of Boerhaave within its precincts; but it is recorded on the joint testimony of Dr. Gregory and Dr. Duncan, that long before this period the fundamental doctrines of that great master had been overthrown by the members of the Medical Society, who, by the substitution of sounder principles, had created the basis on which the splendid reputation of the Edinburgh School of Medicine was subsequently raised.

I have endeavoured to trace the gradual extinction of the tendency to abstract theory and hasty generalisation which clung to Medical Science as its last stronghold until the middle of the eighteenth century. A few years later, however, witnessed its revival in the extraordinary system of Dr. Brown, whose doctrines obtained so great a temporary celebrity from the specious simplicity of their appearance, and the alleged universality of

their application. It will scarcely be denied that no common ingenuity was displayed in the construction of this system, and great acuteness of reasoning employed in the support of it; but there are at present few who do not perceive its inconsistency with facts, and the discrepancy of its own components. The principles on which it is founded are altogether at variance with those of sound philosophy; for not content with a slow but steady advance in the process of induction, raised upon the groundwork of extensive and faithful observation, the creative imagination of the author called up, like the genius in the enchanted tale, that magnificent but unsubstantial fabric, which the superior power of truth was so soon to dissipate. We have still amongst our members many who can bear witness to the enthusiastic zeal with which the Brunonian controversy was carried on in the Hall of the Medical Society. Week after week, the partizans of the opposing doctrines met to continue the discussion: and talents and eloquence often supplied the deficiency of truth. The royal road which this system professed to lay open to the highest principles of our science, was naturally agreeable to the ardent and ingenious as well as to the indolent, whilst the personal character of Dr. Brown was such as to render him a favourite among many of the students. We are at no loss to account, therefore, for the support which he thus obtained on the first promulgation of his doctrines; still less can we wonder that their palpable inconsistency should subsequently induce the calmer judgment even of his partizans to modify or discard them. You are well aware that the Brunonian principles received much greater support on the continent of Europe than in this country; and that notwithstanding the enthusiasm which they excited in the schools of Germany and Italy, a few years witnessed their abandonment by those who had at first so cordially embraced them. Perhaps it would not be difficult, however, to trace in certain pathological doctrines of the modern Italian schools, some lurking remains of this once celebrated system.

It is not my intention to dwell upon the minutiae of the history of the Society, or to enumerate the distinguished individuals who have contributed to its support, since the fullest information on both these topics is within your reach. The most cursory examination of the list of its members must convince you that

Britain has seen few men of high and deserved medical reputation during the last century, who have not risen from its ranks; and many of these have borne honourable testimony to the value of the advantages which they there enjoyed. It must be interesting also to reflect that in this Society have been frequently developed those talents which have subsequently acquired distinction for their possessors in other walks of life. We can scarcely imagine a field more adapted to the display of the classical taste and elevated imagination of Akenside, or the enthusiastic simplicity which characterised the younger days of Oliver Goldsmith. In the number of those who have been honoured with the office of President, our respect and sympathy are excited by the name of the unfortunate Emmett, whose splendid talents were misguided by an erroneous judgment; whilst we give our unalloyed tribute of admiration to the memory of one whose fervid eloquence and mighty intellect so long fixed upon him the attention of his countrymen of every shade of political opinion. Need I mention Sir James Mackintosh?

There is one point of view, Gentlemen, in which some may conceive that the Medical Society has failed in rendering that service to science which its station and capacity would seem to demand from it. All attempts at the regular publication of any of the valuable essays and communications which are constantly being submitted to it, have hitherto proved unsuccessful; not so much, it may be apprehended, on account of deficiency in excellent materials, or from the want of external support, as from the constitution of the Society itself, the perpetual changes taking place in its management, and the close occupation which usually engrosses the time of its most active members. But the world has not been deprived of the benefit of these valuable contributions to medical literature. Many of them have at once been brought into notice through the medium of our periodicals; others, subsequently presented to the world in a more extended form, have contributed alike to the spread of knowledge, and to advance the reputation of their authors, as well as that of the Society from which they originated. The crude and unripened fruits of early mental vigour must be supplied with the nourishing juices of additional information, and mellowed by the calmer judgment

of riper years, before they can be acceptable to the correct and refined taste. And I do not therefore hesitate to say that the stimulus which has here been given to courses of investigation and trains of reflection, whose matured results have been ultimately laid before the scientific world, has been more beneficial than the publication of cumbrous volumes of Transactions, little read, and less appreciated. The only difficulty which I have in producing illustrations confirmatory of this opinion, is the selection of examples. It is probably not generally known that it was in the Medical Society that Dr. Crawford first promulgated his beautiful theory of animal heat, whose ingenuity none can deny, although the soundness of its premises may fairly be questioned; it has been characterised by the learned and philosophic Bostock as "one of the most interesting and beautiful specimens of the application of chemical and physical reasoning to the animal economy that had ever been presented to the world." Here, too, was commenced by the eminent author I have just quoted, that career of physiological inquiry and experimental research, by which he has earned a high and deserved reputation. The favourable reception of the dissertation read by Dr. Currie, on the effect of cold on the living animal body, must have prepared the way for those extended investigations, the publication of which ultimately led to a more correct appreciation of the therapeutic value of this agent. It was to this Society that Dr. Bateman presented his first essay in that branch of inquiry to which he afterwards so successfully devoted himself. It was here, too, that Dr. Henry exhibited his early attachment to the science of which he subsequently became so bright an ornament; and here also were commenced the beautiful researches of De la Rive on some of the nicest questions regarding Caloric and Magnetism. To the members of this Society were first communicated the result of those profound investigations into the physical history of mankind, which have given an European reputation to the name of Prichard. In our hall did the sagacity of Dr. Kay demonstrate the erroneous nature of the opinions of Bichat on the subject of asphyxia, and propound a theory deduced immediately from experiment, which is now received by our ablest physiologists; and there also took its rise the series of investigations into the atmospheric changes produced by animal and vegetable

respiration, which have raised the name of Ellis to a high rank among the original inquirers in this department of science. These works, Gentlemen, are our Transactions; and what Society can boast of having more effectually contributed to the advancement of medical science? It would be easy for me to extend this catalogue by the introduction of the names and works of other authors of no less eminence; but one example more shall suffice. It cannot be regarded as a fact devoid of interest in the history of the Society, that in the dissertations of Professor Jameson are to be found the earliest display of those talents which have been so successfully devoted to the advancement of a science whose gigantic strides and comprehensive grasp are constantly opening new fields of experimental inquiry, and affording new topics for philosophic speculation.

Hitherto I have alluded only to the information with which the records of the Society have furnished me on this subject; had I the means of more extensive inquiry, I might perhaps have been able to mention other works of high and durable reputation as having taken their origin in discussions of which no other memorial remains. It is enough, however, that I can state with certainty that the lectures of Dr. Thomson on Inflammation, and the work of Dr. Wilson Philip on the Phlegmasie, are among the results of debates in which the principal share was taken by these two individuals, whose well earned reputation places them above any eulogy of mine. It must not be forgotten also, that the *Elementa Medicinæ* of Dr. Brown were published whilst their author occupied, for the third time, the chair of the Medical Society.

By another proceeding, not generally known, has our Society contributed largely to the advancement of medical science; and I beg to call your attention specially to this part of its comprehensive scheme, both as one which may, I conceive, be advantageously revived at the present time, and as having anticipated by nearly fifty years, the corresponding plan which forms so prominent a feature of the British Scientific Association. I refer to the appointment of annual committees for the prosecution of interesting inquiries at the common expense, which took place in the year 1784, when the rapid progress of Pneumatic chemistry was opening the way to so many novel and important branches of investigation. In

accordance with the directions given by the Society for this object, we find, as might be expected, that the subjects of respiration and animal heat were among the first on which experiments were commenced; and by these were elicited the valuable contributions of Dr. Goodwyn to this branch of physiology, which were presented to the Society in the year 1786. The splendid discoveries of Galvani and Volta, which followed at so close an interval those of Priestley, Black, Cavendish and Scheele, were not neglected by the members of our Society. Many, I have no doubt, who are now present, can bear their testimony to the enthusiasm with which they were hailed. Not content with their passive reception, the Society provided the means of confirming and extending them; and by recommending the subject to the attention of its members, gave rise to the valuable original experiments of Dr. Richard Fowler, now of Salisbury,) in which he was assisted by Dr. Thompson. It also attracted the notice of the scientific world, by proposing the nature of the galvanic influence as the subject of a prize essay, the competition for which was completely unrestricted; and it is an evidence of the publicity which its proceedings had acquired, that the premium, a gold medal of the value of twenty guineas, was awarded to the elaborate dissertation of Professor Crève of Mentz. It is not a little remarkable that on the list of the apparatus committee at this period, we find the names of Marcet, Henry, Birkbeck, and Roget among the foremost, followed by those of Bostock, Paris, Davy, and Fyfe. It can scarcely be doubted that the taste for scientific inquiry was here fostered, if not originally developed, which has led to the subsequent eminence of these distinguished men.

Of the present state of the Society, it scarcely becomes me to speak. The number of my fellow-members whom I now address is a convincing proof of its prosperity; and its continued usefulness is fully demonstrated by the rank which not a few of them hold among the aspirants after professional distinction. It may be that our discussions are not now carried on with the same enthusiasm which formerly characterised them; but let not this be imputed to any deficiency of zeal on the part of our members, since it is the necessary consequence of the improvements which have been effected in the philosophy of our science. The strict rules of inductive reasoning have

taken the place of the ingenious speculations and brilliant theories of former times; and it is now perceived that the collection and comparison of facts is a more worthy exercise of philosophical skill than the conception of a magnificent but unstable hypothesis. Instead of attempting to construct a showy fabric out of the scattered ruins of some former systems, the pupils of the truly eclectic school of medicine are content to advance with less rapid progress. Their foundation is laid on the sure basis of practical experience, and their materials are derived from every source which the pursuit of truth lays open to them; but carefully keeping in view that every science is nothing more than an expression or arrangement of facts, they exclude every hypothesis which is not the result of induction, and each general statement which is not borne out by observation. Hence, whilst every one is enabled to take an honourable station in the republic of science, none can claim the right of universal domination. The light of true philosophy no longer emanates with dazzling brilliancy from a single luminary, but diffused over countless multitudes of reflecting objects, shines with softer though not less certain lustre on her votaries.

If any tangible proof were wanting that the commencement of our second century of existence is not a period of superannuated dotage, but of youthful vigour and activity, it is afforded by the undertaking of which the present session has witnessed the completion,—the Catalogue Raisonné of our library. To the gentlemen whose united labours have brought this enterprise to a successful conclusion, so eloquent a tribute of praise has already been paid, that any addition from me would be superfluous. I am sure that you will agree with me, however, that a more convincing evidence of the prosperity of the Society need scarcely be sought for, than the fact, that its library, amounting to more than 12,000 volumes, should be regarded as sufficiently complete to render a classified index of its contents a valuable bibliography, not merely to those who have access to it, but to the profession at large; that amongst its members, a sufficient number could be found, uniting talents of no common order, with persevering industry sufficient to execute a task of such magnitude and difficulty; and that immediately upon the completion of the work, it could allot upwards of a hundred

pounds to defray the expense of the publication, without the slightest inconvenience to its funds.

It may be thought that I have dwelt so long on the historical part of my subject, that I have little time to expatiate on the advantages which our Society confers upon its individual members. I shall be sorry, however, if these do not appear evident from the details into which I have already entered. If in past times an ardent thirst after knowledge, a generous emulation in its acquirement, a steadfast pursuit of truth, a clear and unprejudiced judgment, were cherished in the breasts of the illustrious men who have shared our Association, by the opportunities of mental cultivation which they there enjoyed, and of which they have shown the abundant fruits,—can we believe that these ennobling influences are no longer exerted—that from the increased fertility of the soil has resulted any diminution of its products.

Gentlemen, let the memory of the energetic spirits, who, with Promethean skill, united the scattered elements into this giant frame, and animated it with living fire, not be without its effect this day, in stimulating us to carry on their noble purposes with renewed vigour. Their period of exertion has passed, and we have entered into their labours. But though dead they yet speak to us, in the dauntless courage with which they opposed the prejudices of the times, and the unwearied energy by which they succeeded in dispelling them. They speak to us in the noble reputation they have acquired for our institution, and which we are bound by the most sacred ties to maintain. They speak to us in the ardent zeal of their pursuit of truth, which they call upon us to imitate. They speak to us in the individual celebrity which they acquired, and encourage us to similar attainments. And could their spirits be with us this day, to witness the glorious results of their exertions, they would join with us in the earnest desire that the Society which they founded, and which now depend on us for its support, may still be the first in usefulness, as it was the earliest in formation; that as long as Medical Science shall continue to advance, and the pains of suffering humanity be assuaged by the healing art, so long it may persevere in its brilliant course, with undiminished lustre; and that many centenary gatherings of its members may unite, as we now do, in the fervent wish,
—ESTO PERPETUA.

AN ESSAY ON THE ORIGIN AND NATURE OF TUBERCULOUS AND CANCEROUS DISEASES.

(Continued from p. 53, No. 2.)

READ TO THE MEDICAL SECTION OF THE BRITISH ASSOCIATION, ON THE 23RD OF AUGUST, 1836, BY RICHARD CARMICHAEL, M. R. I. A., CORRESPONDING MEMBER OF THE ROYAL ACADEMY OF MEDICINE OF FRANCE, ETC. ETC., AND CONSULTING SURGEON OF THE RICHMOND SURGICAL HOSPITAL, ETC. ETC.

The experiments of Doctors Jenner and Baron strongly support the doctrine of the parasitic nature of tubercle. These pathologists seem, however, to be of opinion, that independent life can only be attached, in the instances under consideration to a substance which at first has the vesicular or hydatid form. In this I differ from them, as I have already sufficiently stated my reasons for concluding that tubercles composed of a medullary parenchyma may also be endowed with individual life; and thus I extend the possession of a proper vitality to an animal mass even apparently less organized than the accephalocystic hydatid.

Doctor Farre, in his work upon Organic Diseases of the Liver, states his opinion also, that a fungous or medullary form of tubercle of that viscus was in possession of a proper vitality, and developed itself by its own innate powers. Doctor Adams, the author of the work on Morbid Poisons, long since advocated the same principle respecting carcinoma, but ascribed it to the hydatid form of existence. But as it is only *occasionally* that we observe in cancer any thing approaching the hydatid form, it is probable on this account that his opinions did not meet with that attention from medical men to which they had undoubted claims. The first edition of my work on Cancer was published in 1806, in which I avowed, without hesitation, my belief in his doctrine, differing from him, however, in this respect, that he placed the vitality in the hydatid structure, whereas, I supposed it to exist in the cartilaginous substance. In this I was manifestly wrong, as the cartilaginous portion is capable of being injected, a fact not then ascertained. But to the medullary portion I now attribute individual

life, not only because it cannot be injected, but because it resembles in structure medullary sarcoma and tuberculous formations in other parts. In the same work, as already mentioned, I afforded some striking facts to induce us to suppose that carcinoma and pulmonary tubercles belong to the same family of diseases; and I understand that the doctrine of the independent vitality of tuberculous diseases is making considerable progress amongst the physicians of Germany.

From the authority of those writers who have favoured, and even espoused the doctrine of the independent vitality of apparently disorganized masses of animal matter, amongst whom are men remarkable for high intellectual powers and deep medical research, you have *a priori* testimony that the doctrine, or if you prefer to call it so, the hypothesis, ought not to be esteemed beneath the attention of this Association; and I flatter myself that I have made out a strong case in its favour, and added some important facts and views towards its support, which will, I trust, awaken your attention to a class of diseases that, under the old established doctrines, have justly been considered as the *opprobrium medicorum*.

If my views of these diseases are correct, and founded in nature, another, but a lower link will be added to the entozoa, which, according to Cuvier, belongs to the second class of zoophytes. The following species may at present be enumerated:—

1st. Tubercle of the lungs and other parts, whether commencing in the form of a grey semi-transparent vesicle, or of a whitish medullary substance.

2ndly. Masses of tuberculous matter in the abdomen, which either commence in the hydatid form or in that of medullary tubercle. These are called, by Doctor Baron, tuberculated accretions.

3rdly. *Fungus medullaris* and *fungus hæmatodes*.

4thly. Carcinoma.

Under these views, it is therefore obvious that the business of our profession is rather to point out the means by which these diseases may be prevented, than in endeavouring by vain efforts to cure them. This observation, however, demands a slight qualification. When a tuberculous disease is merely local or inconsiderable, it may admit of a cure, and the remedial measures upon which I would place most reliance, in addition to

the improvement of the general habit by due attention to diet, air, and exercise, are the gradual introduction into the system of iron and iodine. The first, because it furnishes to the blood not only an ingredient necessary to red-blooded animals, but is a powerful antidote against the inroads of entozoa of every description; and the second, because it is the most powerful agent with which we are acquainted in promoting the absorption of all morbid productions. But when tuberculous formations are general and constitutional, it is irrational to expect that any human measure can prevent the fatal result. What then are the most likely means of protecting mankind from the attacks of those dreadful maladies? The answer is simple and easy. All that is required is *wholesome nourishment, pure air, temperance, and exercise*.

Amongst the lower order of society, those employed in sedentary occupations in crowded manufacturing towns, are by many degrees more prone to them than those who, living by agriculture, labour in the open air, and are not obliged to breathe the impure atmosphere of crowded cities. The former, besides, being prevented by sedentary occupations from taking that wholesome degree of exercise in the open air necessary for the due enjoyment of health, constantly commit great errors in diet, and to these combined causes we may justly attribute their greater liability to tuberculous diseases than their more fortunate fellows whose occupations are in the open country.

The comparative exemption of those who follow agricultural pursuits is, no doubt, owing to their simple and restricted diet, coupled with habits of laborious or active exercise, which occasions a rapid expenditure of the materials of the body, and an immediate demand for more, owing to the acuteness of the sensation of hunger. The high state of activity of their digestive organs at the same time enables them to supply a healthy chyme to replace the exhausted materials, provided that their nourishment be wholesome. The consequence is, that the entire frame is in the most healthy state, every organ performs with energy its allotted function, for every portion of the body is endued with its due portion of vitality. No accumulation of half animalized particles is found in the system fitted to afford a nidus for the growth of parasitic fungi, such as we may presume to occur in the bodies of the indolent, the voluptuous, and the intem-

perate, who gorge their stomachs to excess with a variety of the most nutritious diet, without possessing the powers to digest it.

But multitudes, it will be urged, come into the world with the very seeds of tuberculous disease so deeply sown in their constitutions, that without any fault of their own, those maladies make their appearance immediately after birth, and even in many instances before it. This is true; but it is equally true, that this apparent injustice of Providence is manifestly the natural and inevitable punishment of a breach of the organic and moral laws committed by their parents; who, in despite of disease, of feebleness, of the exhaustion attendant upon old age, and of the deterioration of progeny consequent upon close relationship, without compunction marry, and produce a puny, wretched, and diseased offspring, whose organs are incapable of performing their allotted functions.

The punishment inflicted thus upon the children, and reflected back again upon the parents in anxiety and sorrow, explains and justifies that apparently harsh, but natural and necessary law, that "the sins of the parents are visited upon the children, even to the third and fourth generation." THEN, fortunately, perhaps, a degenerated race may cease to possess the power of propagating its kind.

POSTSCRIPT.

On reading the foregoing paper, which, although it occupied one hour and a half, was listened to with the most flattering attention, the President, Doctor Roget, gave his opinion, that notwithstanding other papers were nominated for a hearing on that day, yet as the subject of the one just read opened a very wide field for discussion, the remainder of the day would be more advantageously occupied in its consideration. Upon which, Doctor Macartney, Professor of Anatomy of Trinity College, Dublin, made, as well as I can recollect, the following objections.

1st. That the vesicular or hydatid-like appearance of tubercles is owing to the circumstance, that they are penetrated by the air cells or bronchial tubes of the lungs, and, therefore, cannot be considered hydatids.

2ndly. That tubercles can be injected, and that he himself had succeeded in injecting them.

3rdly. That the substance of tubercles could be taken up by the absorbents;

from which it is obvious that they are not living bodies, for the absorbents of one animal have not the power of absorbing any portion of the living substance of another.

4thly. That the offensiveness of the breath of a consumptive patient militated against the principle I advocated respecting the nature of tubercles.

5thly. That hemorrhage from the lungs in tubercular phthisis, when it arises from a vomica or tuberculous excavation, is owing to an inflammatory state of the vessels of the lungs, a circumstance not likely to take place on the principle I advocated.

To the first objection, I replied, that tubercles frequently arose on the pleura pulmonalis, or even on the peritoneum in the cavity of the abdomen, and that in either instance it was obvious that the vesicular appearance of tubercle to which Dr. M. alluded, could not possibly be owing to its being permeated by a bronchial tube or air cell. I added, that I did not conceive that tubercles must necessarily exhibit the hydatid or vesicular form at their commencement; on the contrary, I had expressly stated in my paper, that they as often commenced in the form of compact, solid, round, white medullary bodies.

To the second objection, I replied, that if Dr. Macartney had succeeded in injecting tubercles, he had accomplished that which no other person had been able to perform. That our countryman, Stark, was the first to announce that tubercles could not be injected, in which assertion he had been subsequently supported by the united testimony of every pathologist, foreign and domestic, who had treated on the subject. In support of this assertion I pointed to the several fine preparations of tuberculated lungs which lay on the table; in which were displayed compact, rounded, *white* tubercles, into which not a particle of injection had penetrated, while the parenchymatous substance of the lungs surrounding them was rendered perfectly vermilion with injection.

To the third objection, I replied, that the substance of tubercle, while endowed with the principle of life, did not admit of being absorbed; but that when it lost this principle and became decomposed and softened, it was then liable to absorption. That the absorbents were not, however, capable of taking up the earthy particles, carbonate and phosphate of lime, which entered into the composition

of tubercle, that consequently these particles remained behind, and blending with some moist animal matter assumed the consistence and appearance of putty, or chalk and water, contained in a shrivelled cartilaginous cyst, which is the last transmutation (resembling that of hydatids) of such tubercles as do not open into a bronchial tube. The cartilaginous cyst, as I observed in my paper, being the barrier which the surrounding tissues throw up to insulate and check the progress of the increasing entozoa.

To the *fourth objection*, I replied, that when the tuberculous substance, in a softened and decomposed state, is exposed to the air, in consequence of ulceration of one or more of the bronchial tubes in its neighbourhood, of course it undergoes the same fermentable changes to which all dead animal matter is subject when exposed to air, heat, and moisture; and consequently that the breath becomes, as it often does in phthisis, intolerably offensive.

To the *fifth objection*, I replied, that there is no necessity to infer, that hemorrhage from the lungs must be occasioned by inflammation of these organs, when it does not take place from tuberculous excavations; because hemorrhage may be occasioned by the increase and growth of tubercles to so great an extent as to compress the vessels of the lungs, and impede the circulation through them, and from this cause is satisfactorily explained the frequent occurrence of hemoptysis in cases of tubercular phthisis, where no excavations have been found on a post mortem examination.

Doctor O'Beirne inquired of Dr. Macartney, whether he had ever found cellular membrane in tuberculous matter, because it was generally acknowledged, that, whenever blood-vessels ramified, cellular membrane existed to connect them with the surrounding tissues. To this question Doctor Macartney replied, that he *had* found cellular membrane in tuberculous matter. On which Doctor O'Beirne observed, that Doctor Macartney's experience was contrary to that of Doctor O'Beirne, and he believed of all other pathologists.

The only other objection that was urged against the parasitical nature of tubercles was by Dr. Houston; who said, that as I alluded to the post mortem appearances of an axis deer, which he had communicated to the Association at a former meeting, he was induced to state his dissent from my conclusion, that be-

cause the animal had hydatids in its abdomen and tubercles in its lungs, I had reason to infer that the latter, like the former, were parasitic beings; that he, on the contrary, considered the tubercles, in this animal, to be the consequence of inflammation. To this observation I merely replied, that I placed more reliance on his facts than on his opinions, and that I would leave others to judge whether his or mine on this point, as detailed in p. 44) were most to be relied upon.

Doctor Symonds then objected to the manner in which the views of Doctor Carswell, Clarke, and others had been strtd, respecting the identity of scrofula and tuberculous disease, and denied that they supported this identity.

To this objection, I merely replied by referring to the passages from their respective works, as quoted in pp. 9 and 10 of this paper, which prove decidedly that I had not dealt unfairly with them, or misrepresented their opinions.

PROCEEDINGS

AT THE

EIGHTEENTH ANNIVERSARY MEETING OF
THE
HUNTERIAN SOCIETY.

REPORT,

PRESENTED BY THE COUNCIL TO THE
EIGHTEENTH ANNIVERSARY MEETING
OF THE HUNTERIAN SOCIETY, HELD AT
NO. 4, BLOMFIELD-STREET, FEBRUARY
8, 1837.

(Continued from p. 13. No. 1.)

Ascites, or Peritonitis in a new-born infant,—a large tumour appeared a day or two after birth at the scrotum, and enlarged the abdominal cavity, till life was threatened. Twenty-seven ounces of dark glutinous fluid were removed by means of a trochar and canula with relief. In a few days, however, the fluid having again secreted, death ensued: the peritoneal cavity was lined with lymph, and the intestines were glued together by flaky serum.

The different modes of curing *hydrocele* have been considered in connexion with the occurrence of suppuration after injecting the tunic, which suppuration did not hinder a perfect cure of the disease; though instances were adduced of its re-

turn after a similar occurrence. The efficiency of acupuncture to cure hydrocele was supported by arguments and successful cases.

Respiratory Organs.—A man having cut his throat, so as to detach the epiglottis from the base of the tongue, death rapidly followed, in consequence of the lungs becoming filled with blood from the wounded vessels in the neck. From this fact interesting points in physiology and pathology arose; as it proves, with other similar facts adverted to by members, that the arytenoid muscles, though perfect, could not prevent the influx of blood into the trachæa; and further as it bears on the subject of asphyxia, particularly as to the mode of death from exposure to carbonic acid gas. It was agreed that in all cases of cut-throat, the wound should be left to granulate, without being sewn up, and that nourishment should be steadily given, as patients almost uniformly die from suffocation or from the indisposition of the wound to heal; or at length from gangrenous inflammation occurring in the lungs or other organs.

A discussion followed on the propriety of *tracheotomy* in chronic laryngitis, for there is great difficulty in distinguishing minutely the different forms of laryngeal disease, and of fixing the precise time when the operation is needed, and will not prove fruitless from ulceration or phthisis having already proceeded to an incurable extent. In this class of cases, connected as they usually are with phthisis pulmonalis, success has seldom followed tracheotomy. But when acute laryngitis has become chronic, urgent symptoms may demand the operation, which has proved successful when undertaken before ulceration can have been established in the larynx. In croup, where the tube is half closed by fibrin, tracheotomy has often succeeded in the hands of members of the Society; but the success of the operation depends on entirely different grounds from those resulting from ulcerative inflammation of the Larynx.

Abdominal Diseases.—In the report of last year a case was recorded of very large liver in a pregnant woman. She recovered; but in December 1836, an aperture formed near the navel, from which two gallons of fluid, with a large hydatid, which had contained it, escaped. Blood soon gushed forth, and the patient in consequence died. The hydatid had formed in the substance of the liver, surrounded by a fibrinous cyst; the hemorrhage was caused

by the bursting of a large vein of the liver.

Hernia.—The early or delayed application of trusses, &c. in the treatment of congenital hernia in infants was discussed; and although high surgical authority has been adduced to favour a contrary mode, yet it appeared a general opinion that the practice of immediate pressure in these cases has an advantage over that of allowing a long period of time to elapse before it is applied. The cases mentioned went to prove that hernæa have been radically cured long before the expiration of the period when it has been thought by eminent surgeons advisable to commence the application of trusses. Pyramidal plasters were preferred to balls of ivory, &c. in the treatment of umbilical hernia in children.

Irreducible Hernia.—A case of this kind occurred in a female aged 63, it having commenced twenty-eight years before, during her confinement with twins. Inefficient bandages and trusses were employed, and the umbilical tumour became as large as a child's head. Fourteen years after the accident occurred, constipation of the bowels produced inflammation in the sac. An operation was performed which probably liberated the bowel, as relief was speedily given. The hernia was then and has since been irreducible, and if partly returned caused severe dragging pain, till the bowels were again in the sac. In February last pain attacked the abdomen, and became acute in three days; the bowels were inert. On March 1st there were constant bilious vomitings, a moist tongue, frequent feeble pulse, and the sac was rather tender, larger than a man's head, and tense. She died March 3rd, at three o'clock.

Examination.—The peritoneum was slightly inflamed—the blood-vessels supplying the muscular and mucous coats of the intestines extremely congested; dark coloured serum was in the peritoneum. The opening into the sac was large, it contained the ileum, cæcum, and a part of the ascending colon, which exhibited decisive marks of old inflammation in their attachment, by long and very firm membranous bands, to the lining of the peritoneal sac, so that its contents could only be partially returned.

Two other cases of irreducible hernia were detailed, where operations proved unsuccessful. The first in a man with scrotal hernia of ten years' standing, as large as a bullock's bladder, and which

had been irreducible for three years. An accident caused great pain and increase of the tumour. Severe symptoms threatened life,—the operation was undertaken, and the sac was opened, as a division of the stricture had been otherwise ineffectually attempted. The incarcerated intestine was vascular, rough, and adherent by old bands to the lower part of the sac,—these bands were divided, but other adhesions were exposed too numerous to be prudently divided. The wound was therefore closed; the man died the next day from acute peritonitis extending from the sac. Recently effused lymph was found to cover the intestines and peritoneum. The sac contained the sigmoid flexure of the colon, and part of the jejunum adhering to it, by recent and old adhesions.

The other case was one of very large scrotal hernia in a man aged forty years. The hernia had existed twenty-four years, and he had never worn a truss; the tumour was as large as an orange. The operation was deemed necessary, and liberation of the intestine attempted without opening the sac; it was necessary, however, to do so, and the stricture was freely divided, but the intestine still remained incarcerated, and firmly adherent by several bands to the sides of the sac.

Examination.—The bowels were inflamed, and the omentum dragged down to the sac; the communication between which and the abdomen was free. The sac contained the ileum, cæcum, and five inches of the colon, all united by recently effused lymph. The omentum was attached by very firm and old adhesions.

General inferences from these and other cases of irreducible hernia suggested some interesting points for investigation. Among these may be mentioned the causes of the inflammation, rendering reduction impracticable, as it is propagated from the abdomen to the sac, and the consequently appropriate treatment; and whether if an operation be performed at all, it should be performed with or without opening the hernial sac; and if extensive chronic and irremovable adhesions exist, whether it may not be prudent at once to relieve the impeded peristaltic action of the intestine, by making an incision into it.

Sphacelated Femoral Hernia relieved by dividing the stricture only. A lady *Æt.* 45, had a femoral hernia as large as an orange: symptoms of strangulation came on, but she could not be prevailed on to submit to an operation, in order to

their relief, until the fifth day. At that time the pulse was flagging, the tumour numbed, and the tongue furred. The omentum, as well as three-fourths of the calibre of the strangulated jejunum, was found gangrenous. For this reason, and as fæces had been abundantly discharged by vomiting, the stricture was divided, and the bowel, contrary to the practice usually prescribed under such circumstances, left uncut; in the expectation that when the fæces should be propelled downward, the sphacelated part would give way to them. This took place the next day. Suppuration was established, and with far less constitutional irritation than when even dead bowel is divided by the knife. In six weeks the wound healed finally, and the fæces took their natural course.

Four other instances of success, in similar cases, shewed the advantage of the plan over others in connexion with which death usually follows. Moreover it was argued, that by thus employing the knife very sparingly, adhesions, which shut in the gangrenous intestine from the peritoneal cavity, were not disturbed, but were more firm and numerous.

Obstetric Surgery.—At the close of the Report for 1836, an instance was given of *Prolapsus Uteri* being much benefited by removing portions of the vagina, so as to cause its contraction. In fact, the female was thought to have “entirely recovered.” The operator has, however, informed the Society, that the dragging down of the bladder, under which this patient had long laboured, had returned, causing also a *prolapsus vaginæ et uteri*. The neck of the uterus was evidently much elongated; so that the fundus uteri was unsupported by the contracted vagina. Several instances were presented of *elongated cervix uteri*, from the counter pressure of abdominal tumours forcing upwards the fundus, while the retracting action of the bladder weighed down the uterus. The combination of the two complaints would, not improbably, preclude the success of an operation for the prolapsus uteri alone.

Elongation of the neck of the uterus has been reported in a pregnant female to such an extent, that the os uteri protruded beyond the vagina, and the fœtus was supposed to be extra uterine. Premature labour took place; the woman died, and the nature of the case was made clear by the inspection of an ordinary uterus, with a very long neck.

A healthy young woman, regular in

menstruation, became pregnant. On the accession of labor pains, no os uteri could be discovered. She had never suffered pain but had been the subject of leucorrhœa during her pregnancy. In the usual situation of the os uteri, a small indentation was felt; which, after thirty hours ineffective pains, was divided by a bistoury. The opening thus made gave exit to the liquor amnii, and when the head presented, was lacerated by its pressure, till it was capable of permitting the passage of the child. Severe collapse ensued, but she recovered. A month afterwards, careful examination indicated a short vagina, a small uterus without any distinct cervix, and at the end of the vagina, an aperture with three cicatrices, evidently caused by the wound made to aid her labour. About the same time catamenia appeared.

Miscellaneous subjects.—Vaccination. A person was vaccinated with virus obtained directly from a cow. None of the general or local symptoms in the progress of the disease, differed from those in which the vaccine virus has been transmitted through very many individuals.

Veratrine.—The influence of veratrine ointment in delaying pain was noticed, as beneficial in tic douloureux and local rheumatism. In a painful affection of the spine, the vesication produced by applying the ointment was so advantageous, that the patient from being unable to walk a quarter of a mile, could with comparative ease, walk a mile an half.

Bark.—The influence of the various preparations on neuralgic affections may be stated as depending less on the specific form or properties of the different preparations, than on the discrimination displayed in the employment of the medicines, but the ordinary forms are in the majority of cases, efficacious and most certain.

In concluding this brief sketch of the transactions of this Society during the past session, it is satisfactory to remember that the meetings have been once and again occupied upon the late very prevalent and fatal epidemic. But the facts elicited on those occasions are not now recorded, because the Council have the further gratification of issuing the following queries respecting the Influenza, to which they earnestly entreat exact and well ascertained replies.

It is believed that not only will a more accurate record of that disease be obtained from the documents thus transmitted from the members and corresponding

members, than could be produced by unassociated individuals; but also that the Society will thus essentially serve the profession, by analysing the causes and results, in recovery or death, (if the latter describing also the age,) as well as the most successful methods of treatment. The misfortune in medical as in other sciences is, that facts have rarely been sought after by minds unbiassed by preconceived theories, and as seldom have they been fairly recorded. Thus practitioners are influenced more by very general and often imperfectly established principles than they are by precise observations well reasoned upon.

The Council respectfully offer the following questions, upon the disease commonly called Influenza:

1. To what extent has the disease been prevalent within your circle and vicinity, dating its commencement, height, and termination?

2. Was there any thing remarkable as to the health of the population, or the healthfulness of animals, immediately prior to the visitation in question?

3. What character has it usually assumed?

4. What have been the most frequent departures from the more common character; if eruptive, what their form?

5. What have been the termination and sequel of the disease?

6. What treatment was found most successful? And if you had opportunities of witnessing prejudicial results from any modes of treatment, have the goodness to detail them.

7. In the event of your having met with fatal cases, under what circumstances did death occur; and if there were post mortem examinations, what were the morbid appearances?

8. If there are means of knowing, will you have the goodness to say what was the proportion of deaths to the population?

DR. BRIGHT'S
CASE OF A TUMOUR
SITUATED AT THE
BASIS OF THE BRAIN, &c.
(From Guy's Hospital Reports.)

It has occurred to me, within a few years, to witness the symptoms, and, to a certain extent, to watch the progress of two cases, in each of which a tumour had

developed itself within the cranium, nearly at the same point ; and in which there has been so great a resemblance in the symptoms, as to confirm the feeling which I always entertain, and wish to enforce, that in disease, as in other matters, there is a fixed relation, which it is possible we may discover, between cause and effect ; a belief which is indeed essential, in order to render our investigation on the subject of diagnosis satisfactory and interesting. Of course various circumstances always exist which serve to modify, or form a part of the cause on which certain effects or symptoms depend : and hence arises that difficulty which has induced some almost to doubt the possibility of forming any other than a general and indefinite diagnosis in many diseases, particularly those in which the nervous system is implicated. The only way to overcome this acknowledged difficulty, as regards disease connected with organic change, is, to increase the number of authentic cases, in which symptoms and morbid appearances are faithfully detailed.

In each of the following cases, a tumour has been found just beneath the tentorium, in contact with, or actually attached to, the petrous portion of the temporal bone, and pressing aside the pons Varolii. This is a part which seems peculiarly liable to injury, owing to the delicate structures in the neighbourhood, and to the proximity of the internal organ of the ear : besides which, the weight of the head is concentrated near this part, so that fractures of the basis not unfrequently pass directly through the portion of the bone which bounds this region of the brain ; and when a less degree of violence is done to the parts, it is still probable that the groundwork may be laid for such organic changes as will be exhibited in the two cases which I am about to detail.

CASE I.

In November, 1831, I was sent for to Woolwich, to see an officer, a tall athletic man, aged 48, who, after being many years in active foreign service, had returned home in 1817. He married in 1825, and had a family. In 1826 he suffered severely from sciatica of the right hip, which he had injured some years before by a fall from his horse. This was cured by carbonate of iron ; and he afterwards enjoyed an excellent state of health, till the autumn of 1829, when, being again engaged in foreign service, he began to experience an attack of periodic pain

over the left eye, exactly in the super-orbital notch. This pain used to return about dinner-time daily ; and was always put a stop to before he had half finished his meal. At this time he met with a very severe accident ; and was taken up stunned and senseless. He was bled ; and after some hours recovered ; but his recollection was, for a day or two, so defective, that he frequently asked what service they were engaged in, and what they were doing ; and it was with great difficulty these points could be explained to him. However in a short time he was tolerably restored ; though he never regained the state of health he had enjoyed before his fall, frequently complaining of pains in his head, and of some weakness in his right leg.

About Christmas he had a severe attack of bilious vomiting ; after which, the pains in his head and over his right eye were worse, and more frequent ; and he experienced, occasionally, a temporary loss of sight, coming over him like a cloud, and lasting for some minutes ; then passing off, and not being followed by any remarkable increase of the headache. After some weeks of suffering, the intermittent pain over the left eye was completely removed in a single day, by taking three doses of sulphate of quinine in rapid succession two or three hours before the expected diurnal attack ; and is never afterwards returned. In June, 1830, he had another attack of bilious vomiting, of great severity ; which however passed off so quickly, that the following day he was able to resume all his duties ; but shortly afterwards he discovered one morning that the sight of the left eye was completely gone. The sight of the right eye also became imperfect ; the weakness of the right leg increased ; and the left leg also began to lose power. In 1831, when he returned home, the sight of one eye was entirely lost ; and with the other, it was only by great effort, and by changing the field of vision often, that he could distinguish the features of any one with whom he conversed. The hearing of the right ear was tolerably perfect ; but he had for many years lost the hearing of the left, from the shock of a gun firing. He likewise complained much of pain darting through his head ; which was relieved by cupping, blistering, and tartaremetic ointment.

At my first visit, on the 8th of November, 1831, I found him sitting in his chair by his fireside, with his eyes closed,

perfectly unconscious of surrounding objects; so that I conversed with those in the room just as if he had not been present. His wife made him understand, by speaking close to his ear, that Dr. Parker, the physician who had been in constant attendance upon him, had called: and after a few words had passed between them, I was told that I might feel his pulse, or examine his eyes, or do what I pleased, as he would suppose it was only the friend to whom he was accustomed: nor had he the slightest knowledge of my having been present, although I remained with him for nearly an hour, during which an incessant conversation was going on. When after much trouble, by writing words on his hand, by calling in his ear, and by other means, he was led to comprehend, he answered distinctly, and without hesitation, but in the high-raised and ill-modulated voice which is usually observed in deaf people. His intellect seemed unimpaired. He was able to stand; but partly from the weakness of his lower extremities, and still more from the timidity arising from his blindness, he could not move without support; and when he attempted to walk, it was with a short, feeble, tottering step. He had no incontinence of urine, although that had occasionally appeared some weeks before: he had never passed his feces unconsciously, but once or twice there had scarcely been time to prevent an accident of that kind. His sleep was tranquil, and not too heavy; nor did he appear more drowsy than might be expected in a person deprived of sight and hearing. His appetite was good, and had sometimes been excessive. I learnt that about a week before he had experienced a fit, in which he had been for a time insensible, and his countenance suffused, but without convulsion. There was a certain inequality and irregularity in his power of hearing, so that at times he could catch sounds even slight, but not with sufficient distinctness to connect meanings with the words; nor could he be made to understand, even by the loudest voice.

There was no room to doubt that organic mischief was established within the skull: and all I recommended was, medicine to regulate the action of the bowels, and a few grains of the subcarbonate of ammonia, with compound infusion of gentian: his diet to be very plain, and no wine.

November 29th, I again saw him: he seemed more alert, and could hear a little

better; so that he had once or twice distinguished that the drum or bugle was sounding, and heard the voices of his children: and although it was a very laborious operation, yet it was possible to make him hear certain words; and, by the occasional assistance of tracing on his hand words which no effort could make him hear, he was led to comprehend whole sentences; and he then answered correctly, and seemed fully aware of every thing. In this way his wife, who attended him with the most indefatigable care, was able to keep him informed of all that was going on; reading to him the newspapers, in some of the contents of which, particularly as referring to the cholera, then raging at Sunderland, he took great interest. He had sometimes spoken of a very peculiar sensation in his head, attended with a sound as if grease had been thrown into the fire, making a whirling noise, and then dying away, whilst at the same time a flash of light passed over his eyes. With regard to his sight, that also had experienced some occasional improvement; so that the day before our visit, he had said that he could see his whole hand. He was likewise strong on his legs; for with support he could walk three quarters of a mile. His pulse varied from 70 to 75: his appetite was good, and his sleep calm: his bowels easily acted on by medicine. He was ordered to continue his present remedies as long as they seemed to agree, and afterwards to make trial of the arsenical solution; and to begin at once with a succession of blisters at the nape of the neck and behind his ears. A short time after a seton was introduced into the nape of his neck.

I afterwards received occasional reports, by which I learnt that the symptoms gradually increased; the sight and hearing becoming, if possible, worse; the paralysis of the lower extremities more confirmed; the bladder and rectum less under controul; and the mental faculties weakened. I had not, however, an opportunity of seeing him again till the 14th of November, 1832, nearly a year having elapsed since my last visit. He was now lying on his bed, greatly emaciated, propped up by pillows, with his eyes closed, his hands under the bed clothes, and his knees bent up. His wife was feeding him with meat, finely minced, and mixed with potatoes: she was obliged to rouse him frequently, to make him take his food; and then he continued to open and close his teeth gently till he fell

asleep, while the meat still remained partly in his mouth. He had no difficulty or choking in deglutition; but for some months he had not seemed to prefer one article of food to another: and he sipped the most nauseous medicine with as much apparent unconcern as he did wine or any pleasant beverage. I understood that he was subject to some changes, and particularly to more or less drowsy days; and this was one of his bad days. About a month before, he had signified some dislike to medicine, which was considered a sign of improvement; but it soon passed away again; and he now seemed not sensible of any difference in the taste of what was put into his mouth. He was quite unconscious of the presence of strangers, and of all that was going on around him. He seemed in a sort of slumber, except when he moved his mouth to eat, or expressed pain, which he did by drawing up his features when the dressings were removed from his foot, upon which two or three oval ulcers have taken place. I learnt that he was generally taken up about one o'clock, and used to sit in his chair till seven o'clock, when he was again put into bed; but he had lost all power of standing; and although he was perhaps conscious of the calls of nature, he gave no intimation of his wants. He occasionally expressed distinctly severe head ache, and a pain over the right eye. I doubt whether the pupils acted at all: the right was rather the larger of the two. He was never observed to be convulsed. Latterly, a few blisters had been applied to the vertex; but it was quite obvious that no relief could be afforded him.

From this time till his death, which happened on the 27th of December, I did not see him; but I heard that his helplessness had become more and more complete; that he was subject to frequent most profuse perspirations; that the feces and urine often passed unconsciously at the very moment he was taking food; and that the sloughs which were for some time forming upon his sacrum had grown rapidly worse. I witnessed the examination, which took place two days after death, in the presence of Mr. Harris, Mr. Bossy, and his brother, and one or two other medical men.

Sectio Cadaveris.—The scalp rather more bloodless than usual. The skull was hard and solid, and somewhat uneven in its thickness: on each side of the sagittal suture internally, but particularly on the left, it had small deep irre-

gular cavities, which had been filled with corresponding unusually enlarged glandulæ Pacchioni, which seemed to have perforated the skull in some parts, so that only the external table remained. The dura mater was not very vascular, but the projection of the glandular bodies on each side of the longitudinal sinus was remarkable; so that at first they suggested the idea of small cerebiform fungous tumours. A small bony plate also, about half an inch in length, lay along the angle of the falx. The longitudinal sinus was quite natural. The dura mater adhered very firmly to the arachnoid, at those parts where the glands were so large; and when it was removed, the arachnoid in the immediate neighbourhood was white and opaque. The arachnoid was not vascular, nor unnaturally adherent to the brain. There was no serum effused beneath it. The depth between the two hemispheres of the cerebrum was small, owing to a considerable elevation of the corpus callosum. The general substance of the brain was natural, but rather deficient in bloody points.

The roof of the ventricles was raised by clear fluid, of which about four ounces were collected, both the posterior and the anterior portions of the ventricles being distended; but the accumulation appeared greatest in the anterior. A few large vessels, ramified on the internal surfaces of the ventricles, the corpora striata, and the optic thalami seemed flattened; and the septum lucidum was much thicker and firmer than natural. The choroid plexus on each side was exsanguine, and contained several vesicles, from the size of a pin's head to that of a pea. The velum interpositum was also exsanguine.

In attempting to remove the brain from the basis of the skull, it was found that the anterior portion of the cerebellum, on the left side, degenerated into a tumour; and adhered so firmly, that it could not be detached without a scalpel, or employing considerable force, from the petrous portion of the temporal bone. The structure of this tumour was chiefly hard and unyielding, but in some parts softer; and the nervus trigeminus, or fifth nerve, was seen passing over it flattened and broad; nor did the tumour simply adhere, but the bone had become carious and pervaded by it, so that a softened cavity occupied a large portion of the petrous ridge, extending towards the sella turcica.

(To be continued.)

DR. ASHWELL'S CASE
OF
PREGNANCY WITH IMPERFORATE UTERUS.

Eliza P., aged 23 or 24, an Irish woman, residing at No. 103, Little Suffolk street, Southwark, a patient of Guy's Lying-in Charity, was taken in labour, with her first child, on the 14th or 15th of November, 1836. Mr. Roe, the gentleman to whom the case had been entrusted, was called to her at seven o'clock in the morning. He was informed that she had been in strong pain since the preceding evening, but there had been no show as yet. Mr. Roe observed the pains to be urgent and very powerful; but although he remained several hours with her, he had not succeeded in discovering the os uteri.

Puzzled by this novelty (for he had attended a great number of labours), he requested me to visit her. It was then two o'clock; the patient was on her bed. On examination, I found a firm, uniform, globular mass forcing down into the vagina at every pain (which was of great force) but no irregularity upon its surface could be detected; and a very careful examination of the entire vagina whose extremity was easily reached, at all points, failed in detecting the os uteri. As her bowels had been confined for two days, Mr. Roe had administered a dose of castor oil: so we waited a few hours, to see what nature would do, as well as to afford the oil time to operate.

In the evening I again met Mr. Roe to see the patient. Labour pains had persisted, and were of unusual severity: the castor oil had acted once. A most careful investigation of every part of the vagina failed to detect any os uteri. At the upper part of the canal at each pain, there was forced down this tight, tense, globular body, of the bulk of the child's head; and conveying the impression of an entire uterus without orifice.

About the spot where the os uteri should have been, was a minute portion, somewhat thinner than the surrounding parts; but the whole was uniformly smooth, and contained no break whatever. On the receding of the mass, in the absence of the pain, something like a child's head could be felt within.

Inquiries were now made, and the following facts elicited.

Mrs. P. was married on the 4th of February preceding 1836. Since the age of fourteen, she had menstruated every

four weeks, sometimes every three weeks. The discharge was always pale and scanty, and continued from two to three days. She never suffered pain at those periods. She has not menstruated since her marriage.

Both before and subsequent to her marriage, she has had robust health; and in the necessary duties of her vocation has undergone an usual degree of laborious exertion, but she has not had a day's ill health.

For two or three days before labour came on she noticed a rather copious reddish discharge, that continually drained from her, but there was no pain. On the subsistence of this, about the 12th, slight pains in the back were felt, which went on till the night of the 14th, when they assumed the severe and urgent character which occasioned her to summon her medical attendant at the time already stated.

Having satisfied myself, at this second examination, that there really was no orifice into the uterus, the pains continuing of a severe character, and the existence of a living child being proved by the pulsations of the foetal heart, which were distinctly audible, about twice as fast as the mother's pulse, I sought the advice of Dr. Ashwell.

The doctor lost little time in arriving: and having, by a more careful investigation positively confirmed the statement of the condition of parts already made, he determined on losing no more time in making an artificial opening across the above named spot, where the globular body seemed slightly thinner than elsewhere. The patient's pulse was about 120 to 130: very irritable; the pains violent; the skin irregularly hot and cold; the features anxious; the mind irritable; general restlessness; the bowels had now been twice relieved by castor oil. Accordingly, having placed her on her left side, the doctor introduced his left forefinger as a director; upon which he passed up a curved, sharp-pointed bistoury with his right hand; and having punctured the spot already fixed upon, he incised forwards towards the bladder (which was empty) and backwards towards the rectum. At this last incision, a few drachms of dark blood flowed out. The liquor amnii of course escaped; and the head fell on the artificial opening, which proved to be of an inch and a half, or perhaps nearly two inches in diameter and about a line in thickness.

The Doctor did not incise laterally, lest he should wound any of the branches

of the uterine arteries. At one o'clock A.M. of the 16th, he left the patient in charge of Mr. Roe and myself. The pains abated for a brief space after the operation, the performance of which occasioned no suffering; so that she seemed not to be conscious of any thing beyond the inconvenience of manual interference. Pains, however, recurred; but little advance of dilatation appeared to be made for some time, till about four o'clock A.M., when, under the influence of a severe pain, the edges of the orifice tore suddenly towards the right side, and soon after another rent took place, whilst my finger was at the part backwards, towards the left sacro-iliac synchondrosis. At this, she became suddenly faint; the pulse was 140 or 150 feeble; the skin cold and clammy; and she fell exhausted. Æther, ammonia, brandy, and opium were administered, and she rallied. After resting for about two hours, pains recurred gradually, and became as powerful as at any previous time.

The extent of the laceration on the right side could be reached by the finger; it had not extended to the reflection of the vagina; that on the posterior part was beyond reach. No gush of blood attended these lacerations. The head became engaged in the pelvis, and was delivered at eleven A.M.

The latter pains were very inefficient; and much stimulant was administered towards the close. With the child there was a more than usual degree of hæmorrhage; the infant, a male, was asphyxiated, and was with difficulty revived. The placenta was taken away in half an hour, and the uterus contracted well. Nothing further could now be detected, on examination, but several ragged shreds about the orifice at the top of the vagina.

The tongue was dry and brown at tip; the head ached; the pulse was 110, jerking, doubtless referrible in some degree, to the stimulants. Towards the close of the labour, the bowels had afforded three copious motions.

Liq. Opii sedativi. M. xl. statim. And, to meet the expected reaction, Haust. Efferves. cum V. Ant. Tært. et Tinct. Hyosciami aa ʒss 4tis horis.

Barley-water.—Quiet.

Five P.M.—Has been visited by Dr. Ashwell. Pulse 104; no tenderness; tongue moister; bowels once more opened; has voided urine twice. Since the delivery there has been a copious draining, with some clots, which has trickled along the floor, having penetrated the bed.

This is principally urine; but there is evidently also a considerable quantity of blood. She has slept perhaps half an hour.—Pergat.

Eleven P.M.—Has slept an hour, and is refreshed. Free from pain; no sickness; pulse 104. Has drank largely of barley-water.

Liq. Opii ʒss. et pergat.

17th Nov. 10 A.M.—Has slept about six hours. Pulse is only 84 soft; bowels open twice; urine free; tongue white, but moist; moderate perspiration; no tenderness. There has been slight draining, tinged with blood.

Six P.M. I was hastily summoned. She had had three motions in quick succession; and with the last there was much bearing down, followed by severe attacks of pain in the back and in front, with the expulsion of more clots. The pulse was 106, jerking; countenance rather frightened than anxious; there had been no rigour, but there was some pain on pressure over the womb.

Pulv. Opii gr. j. statim.

She was supplied with a bed-pan, with strict injunctions to maintain the recumbent posture, under all circumstances.

Eleven P.M.—Has slept at least three hours. The pain has abated; there is scarcely any on pressure; bowels quiet; pulse 96 softer.

Liq. Opii ʒss. statim, et pergat.

18th March.—Has slept nearly all night, and is quite free from pain or tenderness; bowels open twice, but the pan prevents any discomfort; pulse 90; tongue white, moist.

Rep. Haust. Efferves. sine V. Ant. Tart et Tinc. Hyosc.

Vespere. Has been comfortable all day. Pulse about 90, soft; tongue cleaner; no pain; open once; urine free.

Pergat; et opii gr. i. h. s.

19th.—Slept well; pulse about 100 weak; bowels open twice; no pain; discharge during the night was more profuse, with some clots of blood, but the napkins have been put away; asks for food; there is no milk, but the breasts are filling.

Haust. Efferves. cum. Tinct. Opii. m. v. 4tis. horis.

Liq. Opii. sed ʒss. h. s.

Barley water and gruel.

Nov. 20.—This morning there is an abundant supply of milk in both breasts; the child sucks well from the right, but the left is enormously distended, and has no nipple; there is an extensive areola, with a slight central depression, and no

milk has passed from it : as yet there is no hardness, but she suffers a good deal from distension and pain ; pulse 100, jerking ; tongue moist, slightly white ; bowels once open ; no hardness on pressure over the uterus ; there is a copious offensive discharge, but I have not been able to see a napkin.

Omit Medicamenta—low diet—breast-pump.

22nd Nov.—Mr. Roe used the pump yesterday, and, after much perseverance, succeeded in drawing forward a portion of the areola, and procuring a large supply of milk ; since then, the breast is comfortable and smaller, and the milk oozes from it spontaneously ; pulse 90 ; tongue clean ; bowels open ; sleeps well ; no pain ; is hungry ; discharge abundant ; greenish, muco-purulent, and offensive.

Improve the diet ; et pergit.

24th.—Child cannot seize the right breast, but it is small, free from pain, and the milk spontaneously issues from it ; discharge less in other respects ; doing well.

25th.—Is doing well, and may be pronounced convalescent ; enjoined to keep her bed yet for some days.

4th Dec.—On calling to-day, I find her weak, but well. Since the last report she has had some severe pain and tenderness about the pubes ; for which Mr. Roe, who has been most assiduous in his attentions, applied a few leeches, and the pain quickly subsided. There is still a profuse, greenish discharge from the vagina. Is weak.

Ordered a little Quinine.

14th.—Went this morning with my friend Mr. Gaselee to institute an examination into the present state of parts. It was with difficulty that even a manual examination was permitted.

A day or two after the last reported visit, the discharge assumed a reddish character, and so continued between three and four days ; it commenced, continued, and ceased like the catamenial fluid, and was not attended by any increase of symptoms. She is now nearly free from discharge, and though weak, is at the tub washing.

The following is the result of a careful investigation :—The vagina is short ; its extremity and every part of it can be readily reached by the shortest fore finger ; it presents no other peculiarity. There is no cervix uteri. The uterus seems reduced nearly to a normal unimpregnated size. At the extremity of the vagina, there is a puckered irregular orifice, into

which the tip of the finger can enter. It is soft, with smooth and thick edges, not perfectly circular, in consequence of certain indentions, as if from drawing together of several small rents. It might be compared to the base of an apple, whilst this part of a normal uterus would better resemble the apex of a pear. Radiating from the central aperture can be distinctly felt three ridges, like lines of adhesion, one passing forwards, towards the right ilio-pubic junction, traceable nearly to the reflection of the vagina, one opposite to this backwards towards the left sacro-iliac synchondrosis, whose extremity is lost in the reflection of the vagina, and the third, of short extent, about one-third of an inch long, passing backwards and to the right. These were distinctly ascertained by both Mr. Gaselee and myself, to centre in, or rather radiate from the aperture above named.

The London Medical AND Surgical Journal.

Saturday, April 22nd, 1837.

THE LONDON UNIVERSITY.

The appointment of a REGISTRAR to the Metropolitan University has become a stumbling block to the progress of the new Institution, and it is with pain we have now to state that *intriguing* is busy at work by different parties, each of which is endeavouring to serve a selfish purpose, by getting the important office filled up by a *friend*, in place of selecting some well qualified individual who might have come forward, had it been thrown open to competition. We are not, however, without hope, that as the appointment will not immediately take place, some person will come forward with pretensions of a much higher order than any of the present candidates, and thus leave no excuse for controversy and *jobbing* amongst the senate. Mr. Warburton has not yet, nor is it likely that

he will, relinquish *his* favourite protégé. Certain representatives of the corruption-ists, who became necessarily elected among the senate, are using all their praiseworthy endeavours, to provide for Mr. Daniell, the Chemical Professor of King's College; whilst Dr. Forbes of Chichester has met with an able advocate and place hunter in Dr. James Clark. The general impression at present is, that neither of these jobbings will succeed. The *game* which the Inspector of Anatomy has acquired in executing the functions of his office, and the transactions that have lately taken place at the Home Office, are such as, in all probability, to induce the government not to part with so valuable a servant as Dr. James Somerville; and however well qualified Mr. Daniell may be to lecture to the empty benches of the high Churchmen's College, we have no right to suppose that such talents would render him a competent Registrar of the University. The claims and pretensions of Dr. Forbes are of an order which no one can so well appreciate as his friend Dr. James Clark, and though the mutual feelings of regard and friendship which these two individuals entertain towards each other, so fully exemplified in their works, (we allude to dedications and compliments,) may be highly praiseworthy, it is not a time for Dr. Clark to evince it, at the expense of an important national institution. Without any unkindly feeling towards Dr. Forbes, we cannot help expressing our hope, that the Senate should not make choice of a medical practitioner, more particularly of one, whose humble position in early life, must have deprived him of those advantages of early education and polished habits, which will be so very desirable for the Registrar to possess; but also, because the habits and avocations of all medical practitioners are very different

from those which the duties of the office will necessarily require. An individual ought certainly to be chosen, who, in addition to the education, manners and habits of an accomplished gentleman, has a talent for what is usually called the business of life.

CHAIR OF CHEMISTRY OF GOWER STREET.

The election of a Lecturer to the Chair of Chemistry in this School will not take place until next month. We do not despair of our friend Apjohn's success. We have already informed the public of his high pretensions.

MEDICAL EVIDENCE.

The circumstances which have taken place at the late trial, in reference to the importance of medical evidence, affords a favourable opportunity of calling attention to this most important duty of the medical profession. In doing this we cannot omit pointing out the state of medical evidence in other countries, more especially in France, and comparing the uncertain and very imperfect state of the mode, by which medical testimony is obtained in England, with the highly advanced condition of this branch of the criminal law in other countries. The importance indeed of the competence of medical witnesses has been strikingly exemplified in the case of Greenacre; for had there been any imperfection in that evidence—any incongruity or discrepancy of medical opinion, the most convincing and incontrovertable proofs of the mode by which the deceased had met her death could not have been brought before the jury. Now it is impossible to contemplate the mode—the accidental manner by which that evidence was obtained,

without being struck with the serious imperfection of our criminal court as regards medical evidence. It must be borne in mind, that in the case of Greenacre, the medical evidence rested on the examination of individuals, who are the surgeons of the parish workhouses, and where the parts of the mutilated body happened to be found; and whilst that evidence reflects the highest credit on the medical witnesses, and met with the unqualified approbation of *both* counsel, yet it must be admitted to be a serious defect in the law of this *country*, that the proof of guilt or of innocence of an accused person, should depend on all and sundry, or on any medical practitioner who may be at hand, on the commission of an heinous crime. The evils which may arise, and—which we shudder to confess—may have arisen from the incompetency of medical witnesses, has, we trust, only to be fairly represented to the government of this country, and we cannot doubt that such representation would lead to competent individuals being chosen, from their superior acquirements in different branches of medical science, so that the legislature could, on all occasions, command their services in all cases of death where there was the slightest suspicion of crime. Indeed it is not too much to assert, that there is no public duty to fulfil which the highest knowledge in all the branches of medicine are more essentially requisite, or could be more useful to humanity, than for a country to be possessed of individuals, who can on all occasions be called forward where medical evidence is required.

THE DEATH OF DR. CUMMIN.

We regret that it is our painful duty to communicate to our readers the death of Dr. William Cummin, the joint editor

of the *Medical Gazette*, who expired, after a lingering illness, on the 10th inst., from a disease of the brain. Dr. Cummin was a native of Ireland, was educated chiefly in Dublin, and was a member of the College of Physicians of that Metropolis. When Dr. Roderic M'Leod was appointed one of the Physicians to St. George's Hospital, it was thought unwise that he should continue as the sole and responsible editor of the *Medical Gazette*, and overtures then made to Dr. Cummin, who was then settled in Dublin, to accept the, no very lucrative, and we believe, to his feelings, no very eligible appointment. When we consider the duties which devolved upon him, the controversies he had to contend with, the statements he was compelled to make against the cause of truth and justice, the foul aspersions and the slanders he was stimulated to publish in the *Gazette* against private individuals, these humble duties, duties repulsive to an honourable mind, like Dr. Cummin's, along with the necessity of admitting into his *Journal*, all the contemptible puffings of its subscribers, made the paltry salary of one hundred a year, with a few perquisites, dearly earned. As a Journalist, it must be admitted, he was by no means an able, and far from an elegant writer, though the difficulties he had to contend with, as is too often the case with literary hirelings, may be deemed quite sufficient to account for the want of vigour, and colouring of truth, so palpable in his "leading articles." As a physician, his acquirements were by no means of so mean a description. The Lectures on Jurisprudence, which he has published in the *Gazette*, must be admitted by every one as a proof that he possessed great industry and considerable intellectual acquirements.

PROPOSED CHANGE
IN
CRIMINAL JURISPRUDENCE.

The Convict Greenacre.—Importance of Medical Evidence in Criminal and Civil Proceedings.

To the Right Honorable Lord John Russell, his Majesty's Principal Secretary of State for the Home Department.

My Lord,—Your avowed determination to modify and improve the criminal jurisprudence of this country emboldens me to address you on that most important subject in which you are engaged, and leads me to hope, that you will pardon the liberty I take in presuming to offer you a few suggestions on a matter so deeply interesting to society at large. Having for some years past, devoted great attention and reflection to all criminal as well as civil cases which require the evidence of medical practitioners, and published my opinions regarding them, I trust I may venture to direct your Lordship's attention to many points in criminal jurisprudence, which, in my humble opinion demand your most serious consideration, as well as that of the Government and legislature, and more particularly at so opportune a period as the present. The public opinion is now in favour of a more humane system of criminal jurisprudence, and for rendering it much less sanguinary than the benighted prejudices and ignorance of past ages had deemed necessary.

A recent event has almost wholly engrossed public attention, and particularly directed it to the state of our criminal law. I allude to the case of Greenacre, which is now the universal theme of conversation, and which must have attracted your Lordship's attention, as his Majesty's Chief Magistrate in Criminal Cases.

The trial of Greenacre has created a great sensation among the medical profession as well as the public, and must convince those actually engaged in the practice of medicine, of the indispensable necessity of studying medical jurisprudence, or the application of the medical sciences to the elucidation of civil and criminal proceedings in courts of justice. It is worthy of mention, that no longer than seven years since, the late Dr. Gordon Smith and myself were the only lecturers on the science in this metropolis, and that we memorialized the Apothe-

caries' Society to enforce its study, on account of its great importance. To the credit of the Society, I have to state, that the memorial was immediately attended to, and medical jurisprudence introduced in the Curriculum of the Court of Examiners of the Apothecaries' Society. It is painful to acknowledge that the Royal College of Surgeons has not followed such a good example, though had it not been for the surgical evidence of Mr. Birt-whistle and Mr. Girdwood at the trial of Greenacre, he could not possibly have been convicted. It is to be hoped that the College of Surgeons will now see the importance of the science which has given rise to these remarks, and henceforth enforce its study, and act in accordance with the views not only of the Society of Apothecaries, but of the whole Profession.

In the last number of the *Medical and Surgical Journal*, I gave a brief account of the state of medical jurisprudence on the Continent of Europe, which is so superior to that of this country, and mentioned, that those only who had devoted themselves to its cultivation, were admitted as witnesses in civil or criminal proceedings. The wisdom of this law has been universally admitted by the members of the bar, as well as by the best informed portion of the medical profession in all countries. In reference to the late trial, it may be stated, that some eminent barristers, not engaged in the prosecution or defence, have expressed their opinion, in conversation, both before and since the trial, that the head, body, and limbs of the murdered woman should have been subjected to the examination of a jury of the most eminent members of the medical profession, or of some individuals well acquainted with medical jurisprudence. They further urged, that it did not follow, that because the medical witnesses in this case happened to be able and scientific men, that the bulk of ordinary witnesses are all competent to elucidate such difficult cases, and that therefore, there ought to be a certain number of qualified individuals, to attend coroners' inquests, and the criminal courts, both for the prosecution and the defence of prisoners. I have long entertained this opinion, and have elsewhere defended it;* for without intending the

* Manual of Medical Jurisprudence and State Medicine. 2nd Edition, 1836. By Michael Ryan, M. D., &c. Sherwood & Co., and all Booksellers.

slightest offence to any portion of my brethren, I fearlessly reiterate my conviction, that few of the ordinary medical witnesses, most of whom have not studied medical jurisprudence, are competent to give correct evidence in a large proportion of causes in courts of justice. The force and truth of this position are daily attested by the reports of the evidence of medical witnesses published in the public papers, and numerous examples in proof of it might be quoted. This evil has been long felt, and was in a slight degree corrected many years since, by the admirable Essay of Dr. William Hunter, on "Child-murder," which is highly approved by our learned judges. But have we not known in our own day, the grossest ignorance of medical witnesses in criminal courts, which led to the conviction of innocent persons? Thus a woman was convicted of murder, and executed for the crime, for having mixed arsenic with a dumpling, the only proof of which was, that in the opinion of a medical witness, there was arsenic present, because the blade of a knife was somewhat blackened on being passed into the dumpling. This was no proof whatever of the presence of arsenic in the dumpling. Again, prisoners have been convicted of rape on children by medical testimony, and of having communicated gonorrhœa, though the accused had been free from that disease for months previous to the period of the alleged offence, and the girl had laboured under a genital discharge for five or seven years before the date of the supposed crime. Again, we have it recorded as recent medical testimony, that it is impossible to commit a rape on a girl of ten years of age, though it is notorious that hundreds of children at this tender age are prostitutes in this metropolis, and the life of a felon properly convicted is spared in consequence of such evidence.

It must be needless to multiply examples of this kind, as enough has been now urged to demonstrate the necessity of having proper and correct medical evidence, both in civil and in criminal courts of justice. This is only to be partially secured by the medical corporations enforcing the study of medico-legal questions, or by the legislature appointing certain qualified individuals, of the medical profession, to assist in the prosecution and defence of criminals. Were a law in force to this effect, prisoners would also appoint medical advocates, science and truth would efficiently co-operate, and even-handed justice would

be administered for the protection of the public, and the punishment of offenders.

In a case of this kind, a delicate scrofulous girl, aged eleven years, who had a yellowish discharge from the external genital organs, prosecuted a young man, aged eighteen years, for rape. Two persons, who called themselves surgeons, swore that the capital crime had been committed, and disease communicated. Dr. Gordon Smith, Mr. Whitmore, and myself, were of a different opinion; but the man was sentenced to six months imprisonment. It was clear that he could not have communicated an infectious disease under which he did not labour; and that which was supposed to be such, had existed since the girl was five years old. Dr. G. Smith and myself forwarded affidavits to the Secretary of State for the Home Department (Sir Robert Peel), but the sentence was not disturbed. The prisoner, after the decision of the Home Secretary, declared most solemnly he had never assaulted the prosecutrix; and he was deprived of his liberty for six months, on medical evidence, for a crime he did not commit, and for a disease it was impossible for him to communicate, and which did not really exist in the accused. This case was tried at the Clerkenwell Sessions, Nov. 1829, noticed at length in a letter of mine published in the *Morning Chronicle* of that period. The scientific grounds on which the evidence for the defence rested, is fully described in my work already mentioned. Similar cases are also described by Sir Astley Cooper, in his Lectures on Surgery, in Smith's, Beck's, Paris's, and other works on Medical Jurisprudence; and I have likewise recorded many other examples.

With respect to the medical evidence against the convict Greenacre, I may observe that I was consulted by some of the medical witnesses before the trial of the accused. On a most careful consideration of the account of the morbid appearances, I concluded, in the presence of four medical gentlemen, that the injuries on the eye and back of the head were inflicted during life, that the throat was cut while the body was still warm, and most probably immediately after the infliction of the blow or blows on the eye and back of the head, before life was extinct; and that the appearances about the injured parts could only have been produced, in this case, before death, as they were, what are scientifically termed, ecchymoses, or in common language, bruises, and not cadaverous lividities, or

spots which generally appear sooner or later after death, and sometimes before life is extinct. It was also concluded that it was impossible to state with what substance or instrument the blows on the eye and head had been inflicted; nor was it necessary, in a medico-legal point of view, that the medical witnesses should go farther than to decide, whether the injuries were inflicted *before* or *after* death, and if during life, whether they were sufficient to cause death. With a view to elucidate this question, I drew up, from my lectures on the subject, a description of ecchymoses and cadaverous lividity, and transmitted it to one of the medical witnesses, who was summoned but not examined at the trial, as the testimony of Mr. Girdwood was satisfactory and conclusive. Of that evidence, as a whole, I have given the most favourable and well-merited commendation in the last number of the *Medical and Surgical Journal* (15th inst.), but there was one part of it which referred to the substance or instrument with which the blow was inflicted on the eye, which, as set forth in the public papers, was, in my opinion untenable, and which Mr. Girdwood has since contradicted, in a weekly paper of great circulation, as appears by the following letter:—

To the Editor of the Weekly Chronicle.

Sir—In the account given in the daily papers of the trial of Greenacre, there are, in the medical evidence, many inaccuracies and much obscurity. Even in the reports given in the *Times* and *Morning Chronicle*, in which latter newspaper especially, much attention has been devoted to furnish an accurate account, the typographical errors has sometimes destroyed the meaning of a sentence, *evidently* correctly reported. The weekly journals may have time to correct these inaccuracies; and, as I find you have devoted much attention to the whole affair, I am induced to express thus much to you, as your very immense circulation throughout the kingdom requires that your account should be as correct as possible.

In some accounts I am made to say that the blow on the eye *must* have been inflicted by the fist. I left the mode in which the eye was struck doubtful; the prisoner was entitled to the benefit of any doubt. "It might have been the fist; it might have been something smooth; but not any thing angular or having sharp edges." These were my

expressions. But what I am most anxious about is to have clearly expressed the description of *ecchymosis*, the consequence of a bruise on a living body, as distinct from *livor*—the settling of the blood in the dead body. In particularizing the differences, I left out the discolouration on the surface, and the yellow edge around it, which I found by experiment might be to a certain extent simulated on the dead body, and confined my enumeration of the phenomena resulting from and peculiar to a bruise in the living body, the effusion of blood throughout the substance of all the tissues affected by the blow; to the existence of red blood in the minutest vessels of the tissues where, in natural condition of the body, it does not flow; and lastly, to the existence of swelling of the injured part. It was on the two last appearances I now describe that I principally rested my proofs of injuries during life.

I have the honour to be, Sir,

Your obedient servant,

G. F. GIRDWOOD.

Paddington, Thursday.

The importance of distinguishing ecchymoses or the result of an injury inflicted on the external surface of the body, or on deep seated organs during life, from *blows* or *lividity* on the dead body was not so much dwelt upon by the learned Counsel for the prisoner as might have been done; and had they been properly informed on the value of this point, which could only be done by medical advice, they might have thrown some degree of doubt on the conclusion of the Medical Profession, as to the pathological differences between ecchymosis and cadaverous lividity; for though generally received, the decision is questioned by some, though few, learned medico-legal authors, and is by no means positively determined in some cases. Nevertheless, the weight of medical authority is in favour of the difference between ecchymosis and cadaverous lividities, though the slightest doubt would have been in favour of the prisoner, and this would have had great influence with the Court and Jury had he not confessed that he inflicted the blow on the eye during life. But had he not acknowledged this fact, and had the medical witnesses been closely examined on the scientific distinctions between the effects of blows, or wounds, inflicted during life, and on a person in good health, or on one in delicate health and broken down constitution, immediately before or after death,

or when the body was exsanguinated after decapitation, or when cadaverous rigidity was accomplished, or decomposition advanced, a considerable doubt would have been excited, and I maintain that cases might occur in which it would be extremely difficult, if not utterly impossible, to convict prisoners accused and guilty of the crime of murder, solely upon medical testimony.

These facts clearly prove the importance of the science of Medical Jurisprudence to Counsel, to Judges, and to Jurors, and the advantages that would arise to prisoners on trial for their lives, if they had the aid of medical witnesses, who might make most valuable suggestions to their Counsel. A great beneficial change has been lately made in the criminal law by the Prisoners' Counsel Bill, and an opportunity now occurs to your Lordship in your proposed alterations of Criminal Jurisprudence to give prisoners as well as prosecutors the advantage of correct medical evidence, by enforcing the necessity of such evidence in all cases for the defence as well as the prosecution.

Another great improvement in Criminal Jurisprudence would be that Coroners should be of the Medical Profession, or, at all events, be advised by Medical Practitioners, in their investigations. This is my conviction after much reflection on the proceedings of Coroners' inquests, as will appear from my work on Medical Jurisprudence and State Medicine.

It will be argued against the proposed change, by the legal profession, who, it is to be remembered, are interested in the matter, that no one but one of their body ought to be appointed Coroner; but to this it may be replied, in addition to the arguments already urged, that Medical Practitioners and private gentlemen are now Coroners, and that no complaint is raised against the manner in which they discharge their duties. But suppose attorneys continue Coroners, there is no reason why they should not have the aid of proper medical advice, as well as Counsel and Judges, which in most cases would greatly facilitate the ends of justice. Magistrates ought, likewise, to be advised by Medical Practitioners. It is scarcely necessary to observe that a vast number of distinctions exist in different trials for the same crime, which can only be proved by medical evidence. All these distinctions may be modified by age, sex, habit, temperament, state of health, or disease, by season, climate, position of the body, and other causes which I

have fully described in my work already alluded to. The investigation of these and numerous other questions affecting reputation, property, liberty and life, which become matters of judicial inquiry, are familiarly discussed in recent works on Medical Jurisprudence, and may be perused with instruction and interest by Judges, Barristers, Solicitors, Coroners, Magistrates, Jurors, as well as Medical Practitioners, and all classes of society. These works contain a vast number of questions, both civil and criminal, which are as yet but partially studied by Medical practitioners, in relation to public morals and health, as marriage, population, pregnancy, abortion, infanticide, female violation, legitimacy, divorce, attempts against health, or life, homicide by contusions, wounds, strangulation, suffocation, hanging, drowning, poisoning, questions relating to liberty, mental alienation, disqualifying diseases for witnesses, jurors, soldiers, sailors, for corporal punishment, life insurances, adulterations of aliments and drinks, burial of the dead, nuisances, putrefaction of animal or vegetable substances, erection of certain manufactories, buildings for numerous inmates, sanitary laws, or those relating to contagious diseases, dangers incident to certain situations, effects of arts, trades, and professions, and of civic states and habits of living, on health and longevity.

It is scarcely necessary to observe that the best medical evidence ought to be produced for plaintiff and defendant in all civil cases, and for prosecution and prisoners in criminal trials; but this, I grieve to indite, is by no means the case in either class of judicial investigations, unless when the wealthy are concerned. The only remedy, in my opinion, is legislative enactment, which should authorise or command the attendance of proper medical evidence, in every class of cases in which such testimony is necessary for the furtherance of the administration of public justice.

This is the law in France, Germany, Prussia, Italy, and most continental States, and is one well worthy of adoption in the administration of the law in this country.

I have the honor to be,

My Lord,

With profound respect for your

Lordship's high talents,

Your most obedient humble Servant,

M. RYAN, M.D.

4, Charlotte-st., Bloomsbury-sq.

April 22, 1837.

MEETING OF THE PUPILS OF GUY'S HOSPITAL.

A very numerous meeting of the pupils was held by permission in the anatomical theatre on Monday, the 10th of April, which was attended by nearly all the medical and surgical officers of the hospital, and lecturers. The large theatre was crowded to excess. On the motion of Mr. Aspland, seconded by Mr. Tamplin, Mr. Oldham was called to the chair. After this gentleman had opened the business of the meeting in a neat and eloquent speech, Mr. Tweedie read the report of the committee, after which the following resolutions were proposed and seconded.

Guy's April 10th, 1837.

1st. Resolution. Proposed by Mr. Ridge, seconded by Mr. Hemming. "That we have witnessed the late prosecution with feelings of personal interest, being fully sensible of the unworthy attempt which has been made to injure the general character of our school: and we offer to our fellow pupils against whom the indictment was preferred, the fullest assurance of our friendship, esteem, and regard."

Carried amidst loud cheering.

2nd. Proposed by Mr. Gaselee, seconded by Mr. Nankeville. "That the pupils of Guy's and their friends do raise a subscription to assist in defraying the expenses which the late prosecution has imposed on the defendants."

Carried unanimously.

3rd. Proposed by Mr. Lever, seconded by Mr. Morrish. "That the committee, with power to add to their number, be requested to continue to act as heretofore, and to take the necessary steps for collecting and appropriating the subscriptions."

Carried unanimously.

4th. Proposed by Mr. Carrington, seconded by Mr. Aspland. "That the kind interest which the treasurer has manifested in the late proceedings has evinced another proof of the anxiety which he ever feels for the character and prosperity of the pupils of this school, and that our best thanks are due to him accordingly."

Carried by acclamation.

5th. Proposed by Mr. Godfrey, seconded by Mr. Brereton. "That we feel but little regret in hearing that a resolution of the governors of St. Thomas's has unjustly deprived us of our long established privilege to attend the surgical practice of that hospital; for we have every confidence in the ability and kindness of our own teachers, and are per-

fectly satisfied with the ample opportunity for study to be found at Guy's Hospital."

Carried unanimously.

6th. Proposed by Mr. Tweedie, seconded by Mr. Cock. "That the pupils of Guy's Hospital feel it due to their legal adviser, Mr. Price, to declare their deep sense of the exertions and ability exercised by him in the defence of their friends: and they thank him most sincerely for his liberal contribution of fifty guineas towards the subscription which has been instituted to assist in defraying the expenses, and that the committee do convey to him the foregoing resolution as a testimony of the feelings of the school."

Carried amidst loud cheering.

7th. Proposed by Mr. Mosgrove, seconded by Mr. Tomlinson. "That the thanks of the pupils be given to the committee for the manner in which they have performed their duties."

Carried unanimously.

H. Oldham, *Chairman*.

8th. On the motion of Mr. Chapman, seconded by Mr. Hopgood, thanks were accorded to Mr. Oldham for the able manner in which he had presided, after which, the meeting was dissolved.

In connection with the 5th resolution, the following document was read from the chair:—

We, the under-signed medical officers and teachers in the school of Guy's Hospital, hereby assure the gentlemen composing the classes, of our sense of the greatest attention and uniform propriety of conduct evinced by them, on all occasions; and express our unqualified opinion, notwithstanding the late untoward circumstance, that nothing has occurred to deprive them of our confidence and regard.

Henry James Cholmeley, M.D., William Back, M.D., Richard Bright, M.D., Thomas Addison, M.D., Physicians to the Hospital.

Samuel Ashwell, M.D., Obstetric Physician and Lecturer.

Astley Paston Cooper, Consulting Surgeon.

C. Aston Key, John Morgan, Bransby B. Cooper, T. Callaway, Surgeons to the Hospital.

Thomas Hodgkin, M.D., Lecturer on Morbid Anatomy.

Thomas Bell, Surgeon Dentist to the Hospital, and Lecturer on Comparative Anatomy.

Edward Cock, Lecturer on Anatomy.

Arthur Aikin, Lecturer on Chemistry.

Alfred S. Taylor, Lecturer on Chemistry and Medical Jurisprudence.

Thomas Wilkinson King, Demonstrator of Morbid Anatomy.

Charles Johnson, Lecturer on Botany.

James Stocker, Apothecary to the Hospital.

Golding Bird, Lecturer on Experimental Philosophy and Medical Botany.

John Hilton, Demonstrator of Anatomy.

G. H. Barlow, M.D., Lecturer on Practical Pharmacy.

Jabland, J. Edinborough, Assistant Surgeon to the Ophthalmic Infirmary.

John C. W. Lever, Demonstrator of Materia Medica, and Clinical Obstetric Assistant.

Alexander Tweedie, Clinical Obstetric Assistant.

As Chaplain of Guy's Hospital, I have read Lectures on Moral Philosophy, to as many of the Students of the Medical School as had leisure and inclination to attend, and have uniformly received from them the most respectful attention. I have also had opportunities of observing the deportment of the students generally, which has always seemed to me most becoming and orderly. F. Maurice.

As Steward of Guy's Hospital, I have the best means of knowing the Students, and from that have an unqualified feeling of regard to them for their orderly, gentlemanlike conduct, together with their strict observance of all the regulations of the establishment. James Browell.
Guy's Hospital, April 10th, 1837.

ROYAL COLLEGE OF SURGEONS IN LONDON.

The ensuing course of lectures in the theatre of the college, by Professors Stanley and Owen, will be commenced on Tuesday the 18th day of April next, at four in the afternoon, and will be continued on Tuesdays, Thursdays, and Saturdays, at the same hour, until completed.

The first part of the course, consisting of six lectures on Human Anatomy and Surgery, will be delivered by Professor Stanley; and the second part of the course, consisting of twenty-four lectures on Comparative Anatomy, will be delivered by Professor Owen.

Tickets of admission thereto will be delivered to members of the college, between the hours of twelve and four, upon personal or written application to the Secretary. By Order

EDMUND BELFOUR.

March 1837.

Secretary.

Members who have not obtained tickets of admission, will be admitted on presenting their cards, or on writing their names in a book.

REGULATIONS RELATING TO THE LIBRARY AND READING ROOM. The library is open daily, Sundays excepted, to members and articulated students of the college, from ten until four o'clock, except during the month of August.

Other persons desirous of admission must make application, in writing, to the library committee, specifying their christian and surnames, rank or profession, and residence.

Tickets of admission are granted for six months, at the expiration of which time application must be made for their renewal.

Readers, taking extracts from any book, may not lay the paper on which they write on any part of such book; nor may any tracings be taken from any plate without the permission of the committee.

Books belonging to the college are not to be written upon; and any one observing a defect in a book, is requested to report the same to the librarian.

Readers, desirous of consulting works not in the library, are requested to communicate their wishes, in writing, to the Librarian, in order that the same may be reported to the committee.

The admission tickets are not transferable.

The reading room is open, to members of the college only, from seven until ten o'clock on the evenings of Tuesday, Wednesday, and Thursday:—but no person can be admitted after nine o'clock.

The reading room is appropriated to the British and Foreign Journals; and works published or presented to the college within the preceding twelve months.

Members wishing to refer to books not in the reading room must furnish the librarian with a list thereof before three o'clock of the day on which they will be required.

Works of great value, and particularly books of plates, can only be referred to in the day-time in the library.

All books taken out of the library for reference in the reading room must be delivered back the same evening to the officer in attendance.

Every person upon admission to the library or reading room is required to insert his name and address in a book provided for that purpose.

EDMUND BELFOUR,

March 1837.

Secretary.

[We regret to learn that few of the members of the college have as yet availed themselves of the above advantages, but we have no doubt when more generally known, that the library will be fully attended in the evenings. The council has done well in throwing it open to the members at large, and we feel pleasure in adding that other acts of liberality are under consideration. Eds.]

FOREIGN MEDICINE.

Cure after excision of a portion of the intestine.

BY PROFESSOR DIEFFENBACH.

A strong man, aged fifty, had suffered for fourteen days from strangulated inguinal hernia of the right side. Several ineffectual attempts at replacement had been made. At this time, Dieffenbach saw the patient. In addition to the usual symptoms, there was reason to suspect sloughing of the protruded parts, and escape of fecal matter into the hernial sac. An incision of about three inches in length was made into the swelling; when an ichorous fluid escaped with fecal matter, and portions of mortified intestine. The diseased intestine was drawn outwards, and three inches of it, which were partially mortified, softened and thickened, together with a corresponding portion of the mesentery, were cut away. A small artery of the mesentery required to be tied, and the ligature was cut close to the knot. During this process, the ends of the intestine were held by assistants. The angular incision in the mesentery was first united by ligature; and then the extremities of the divided intestine, by means of separate threads, so inserted as to bring the peritoneal coat alone into connexion. The mucous membrane was not perforated. The parts were then carefully replaced. Shortly afterwards, castor oil was administered, and repeated with some croton oil, until very large evacuations were produced. These were followed by great improvement in all the symptoms. Mild aperients and the antiphlogistic regimen were the only means required during the process of cure, which was complete in the fourth week after the operation.

The individual returned to his usual employment, which was laborious, and some weeks subsequently, after very hard work, and the use of very indigestible food, he was suddenly seized with all the symptoms of intus-susception, with which he died. Two diseased conditions were

found in the abdomen. In the left lumbar region a portion of small intestine had coiled around, strangulated and become adherent to, another portion of the same gut; above this, the ileum and jejunum were much inflamed, adherent and covered with flakes of lymph, and contained a large quantity of excrementitious fluid, which was also found in the duodenum and stomach. The ileum, particularly near the strangulated part, was very much distended by this fluid.

Beneath the strangulation the intestine was empty and contracted, passing in this state to the right inguinal aperture, at which many convolutions were closely adherent. Whilst dividing the false membrane which united the intestine to the inner parietes of the abdomen at this part, a drop of pus was found surrounding a ligature. Here was the part of intestine which had been operated on. It was closely adherent to the abdominal parietes and the contiguous convolutions of intestine. On cutting it open, the extremities which had been joined together by ligature, were found to be connected by a smooth cicatrix, interrupted only by the situations of the ligatures, still suppurating. The ligatures were adherent, and their extremities lay in the cavity of the intestine. The portion of intestine beyond, about a span in length, terminated in the cæcum. Nothing worthy of remark was found in the other organs.

Wochenchrift für die gesammte Heil Kunde.

Mark of Royal Favour to Sir Astley Cooper.—Sir Astley Cooper, serjeant surgeon to the King, received at the last levee, the Grand Cross of the Royal Hanoverian Guelphic Order, and the distinguished Baronet was presented at Court by his Grace the Duke of Wellington.

Phrenology.—The murderer Bartlett before his execution at Gloucester, expressed a desire that his head should be examined by a practical phrenologist. This circumstance is supposed to have led Dr. Elliotson, whose phrenological tact far exceeds even his stethoscopic acumen, to examine the head of Greenacre, which through the official channel of Mr. Mac Murdo, the newgate apothecary, he was enabled to accomplish. We understand the doctor's examination was highly satisfactory. Greenacre submitted to the application of the *callipers* without a frown, and appeared intensely anxious that the measurement of his head should coincide with his confessions. ogle

L'Homeopathy, Comédie-vaudeville en un acte par M.M. FOURINER et de Biéville. 8vo. pp. 15. Paris, 1836.

This is the first time in our capacity of reviewers that we have been called upon to notice a melo-drama. But homeopathy, that medical innovation, pronounced by the French Academy of Medicine to be "a dangerous mode of treatment, and the offspring of quackery," forms the subject of a *vaudeville*, first represented at the theatre of the Gymnase-Dramatique, Paris, on the 13th of October, 1836.

We shall not enter into the merits of the piece as a dramatic composition, but content ourselves by saying that its authors have furnished in a brief dialogue a better exposition of the system than any we have yet seen, not excepting the "Organon der Heilkunst," of the arch-heretic Hahnemann himself.

A roguish valet gifted with strong gastronomic propensities, or what, in the language of an infant *science* would be termed undue development of the organ of *alimentiveness*, is detected purloining some savoury morsels of a rich Strasbourg *pâte*. The homeopath in attendance, Dr. Fritzback, ordains that the varlet "be prevented, under pain of dismissal, having any other nourishment whatsoever for during eight consecutive days, than *pâte des foies gras*."

Here a perfect cure was accomplished.

A sprightly young *femme de chambre* in like manner troubled with excess of conjugal affection, is compelled to live for two months uninterruptedly with her husband. She completely recovers before the time given has expired.

But we hasten to the dialogue, (page 6,) which may be said to contain the very pith of Hahnemannism.

Darneley, in love with a young widow, falls in with Fritzback, an old college companion, now the zealous partzan of Homeopathy.

"FRITZBACK. One day Hahnemann, reflecting on the enormous quantities of that *routiniere* and impotent medicine which has sent so many people into the other world, transported with indignation, was on the point of tearing in pieces his doctoral robe, and renouncing so unworthy a calling, when, inspired by heaven, the idea struck him of administering a potent dose of peruvian bark. Oh happy thought! Oh precious inspiration! was that Peruvian bark.

DARNELEY. Well, what then?

FRITZBACK. Why the bark made him fever like a horse, all but killing him.

DARNELEY *bursts out a laughing*.

FRITZBACK (*amazed*.) Well, this is always the way with men of the world—incredulous, ignorant, they laugh without understanding why.

DARNELEY. But my friend, (*still laughing*.)

FRITZBACK. If you laugh thus, let some one else explain this admirable science; as for me, I shall abandon you in your next illness to ordinary physicians.

DARNELEY. Well, I'm composed now.

FRITZBACK. This profound observer, Hahnemann, I say, ascertained that while in good health, he was attacked with ague after swallowing a dose of bark, and that ague was caused by bark.

DARNELEY. Argued in a superior manner!

FRITZBACK (*with a triumphant air*.) He therefore inferred that bark can determine a fit of ague. But, on the other hand, bark is the remedy for ague. Do you perceive? Do you begin to comprehend the consequence?

DARNELEY. No; not precisely.

FRITZBACK. Do you not foresee that the substance which cures, may also produce an ague. And if this principle be general, then, as there is no malady which cannot be innoculated, there is also none which cannot be cured; the small-pox by the small-pox, otherwise called *vaccine*; like by means of like. Well, this principle is general, and in order to convince himself thereof, Hahnemann tried in succession all kinds of substances on his relatives, his friends, his acquaintances, on myself, who have had the good fortune to approach him; he made the whole of us ill, and restored us again to health . . . more or less! And yet your heart does not palpitate with enthusiasm at the sound of the name of this grand benefactor to humanity. (*Aside to Darneley*.) If you wish, by chance, more ample details, buy my pamphlet, published by Denain, superfine satin paper, price two francs and a half.

Courteous reader, Darneley was at length persuaded; if thou art not, put thy hand into thy pocket and expend four sous for the *Piece de Theatre*. Should that not suffice, then purchase the *brochure* of Denain.

London Medical and Surgical Journal.

SATURDAY APRIL 29.

Vol. I.—(1837.)

NOTES OF LECTURES ON PHYSIOLOGY.

BY DR. FLETCHER.

*Delivered in the Argyle Square School of
Medicine, Edinburgh.*

No. XX.

THOUGHT.

Phrenological Organs—Benevolence—Large in Henri Quatre, Raphael, and the Lion—Deficient in Bellingham, Carib Indians, and the Tiger—Mode of detecting a vicious Horse—Veneration—Portraits of our Saviour and the Saints—Difference between the Heads of Whigs and Tories—Hope—Ideality—Organ of the Sublime and Beautiful—Homer, Shakspeare, and Walter Scott—Poets and Orators—Love of Justice—Small in Bruce, Haggart, and Savages—Detail—Organ of Curiosity and Story-telling—Form—George the Third—Remarkable Instance of his Good Memory—Size—Mechanical Talent—Weight—Cause of Inability to Stand in Drunkenness—Colour—Haydon and Wilkie—Place—Navigators, Travellers, Descriptive Authors of the Day, and Migrating Birds—Order—Slovenliness—Time—Number—Good Calculators—Music—Catalani, and the Italians—Mozart and the Germans—English and French—Language—Goggle-eyed Scholars—Comparison—Organs of Reflection—Burke and the Hindoos—Metaphysics—Philosophical Forehead—Wit—Rabelais and Sterne—Imitation—Actors—Objections to Phrenology refuted—Lavater on Physiognomy—Elementary and Compound Thoughts—Convulsions in the Ape and in Man—Dr. Fletcher's Opinion of Phrenology—Advantage of Consulting a Pillow—Circumstances which promote the Activity of Thought—Voluntary Motion—Motions subservient to Respiration—Compass of the Voice—Mechanism of a Musical Shake—Vocal Muscles—End.

No. 4.

less Variety of Tones which they produce—Infinitesimal Difference between a True and False Note—Howling Ape—Voices resembling a Flute and a Whistle—Vocal Organs in Birds—Mode of Imitating the Song of Birds—Animals without a Voice—Cause of the Noises made by Grasshoppers, Flies, Gnats, and Beetles—Whispering—Musical Snuff-Box in different Gases—Motions subservient to Digestion—Structure of the Teeth in different Animals—Artificial Teeth—Tongue-tied Infants—Motions subservient to Sensation—Expression of the Eyes and Nostrils—Paintings of Hebe—Motions of the Body in general—Locomotion in Oysters—Unity of Organization in Reptiles, Fishes, and Insects—Structure of Bones—Impregnation of Bones with Madder—Muscles of the Neck in Man, Quadrupeds, Tortoises, and Birds—Mode of Curing a Stooping Gait—Structure of the Spine—Proper Attitude for Statues—Standing at Ease—Going on all Fours—Sleep in the Erect Posture—Shakspeare's Definition of Bowing.

13. *Benevolence.*—Situating just before the anterior fontanel. It is large in Henry the Fourth of France, and in Raphael. It is also large in the lion, but is deficient in the tiger, and most other carnivora; as it is likewise in Bellingham and the Carib Indians. By observing whether this part is well developed or not, a vicious horse may be distinguished from a mild one.

14. *Veneration*—This and the four following organs are proper to man. It is larger in females than the other sex; and is very large in the pictures of the saints, and of Jesus Christ. It is larger in Tories than Whigs; the former being fond of old institutions. In Mac Innis it is very large; and she was very superstitious.

15. *Hope.*—Very large in Raphael.

16. *Ideality.*—This is the organ of

imagination. It is large in all poets and orators, from Homer downwards. It is the organ of taste, and of the perception of "the sublime and beautiful." It is large in Henry the Fourth, Raphael, Haydon, Wilkie, &c. Above this organ is a blank space; but which is said to belong to the organ of the wonderful. It is large in Shakspeare and Sir Walter Scott.

17. *Love of Justice.*—It is deficient in Savages, and their word is not to be believed. It is small in Bruce, Bellingham, and Haggart.

18. *Firmness.*—Placed between the organs of pride and veneration. It gives a hard and forbidding, but not a pompous manner. It is characterized by pursed-up lips; and is well exemplified in Bruce and Haggart. The English as a nation, and males in general, have it large.

19. *Detail.*—This is the first of the faculties. It gives a talent for minute observation. It is large in children, and their curiosity is endless. They are fond of telling long stories, and for this they are indebted to the organ of detail.

20. *Form.*—Situated between the eyes. It is very large in George the Third; who, it is said, never forgot those who had been once introduced to him.

21. *Size.*—This organ implies a talent for mechanics.

22. *Weight.*—The influence of this organ is interfered with in drunkenness; and hence a person in that state loses his equilibrium.

23. *Colour.*—This organ is of great importance in painters. It is large in Haydon and Wilkie.

24. *Place.*—The faculty imparted by this organ, takes cognizance of the relation of things. It is large in navigators, travellers, and descriptive authors (such as Walter Scott); and likewise in the dog and migrating birds.

25. *Order.*—This organ is opposed to slovenliness.

26. *Time.*—In those who have this organ well developed, it regulates every movement.

27. *Number.*—Very large in good calculators; Bidder, for instance.

28. *Music.*—Larger in the Germans and Italians than in the English and French. It is well seen in Catalani, Mozart, &c.

29. *Language.*—Gall observed, that all who were clever at learning languages, had goggle eyes.

30. *Comparison.*—This organ, and the three following, relate to reflection. It

is large in those who are clever at analogies, as in popular orators; and likewise in the Hindoo, Raphael, Henry the Fourth, and Burke.

31. *Metaphysics.*—This organ imparts the faculty of reasoning deeply; and of building one thing upon another. It is the opposite of the organ of detail. It expands the forehead, and is large in all philosophers.

32. *Wit.*—This organ gives the talent of combining congruous and incongruous things. It is very large in Rabelais and Sterne; the latter of whom is always drawn with the finger pointing to this organ.

33. *Imitation.*—This organ is very large in actors of distinguished talent. It is well developed in the head of Raphael.

It is not a valid argument to say, that the skull does not accurately correspond to the brain; for in the infancy of phrenology, the brain was not thought of. It was a subsequent observation, that the brain generally corresponds to the skull. In a similar way, Lavater founded his system of physiognomy on the expression of the countenance, without entering into a consideration of the muscles and nerves of the face. Phrenology has an equal right to stand on the ground of observation. It is thought that the cones which are expanded from the tuber annulare, are the seats of different modes of thought. But this is a *petitio principii*. I think the effects we observe from lesions of the brain are not compatible with the local residence of elementary forms of thought. The forms are compound. Again, the measure of the external surface of a part of the brain is not the measure of the actual surface, for it takes no notice of the convolutions. Thus phrenology would give the same measurement of an organ in an ape and in a man; although the convolutions are very different in the two: I believe in phrenology on the large scale, taking the mean of the aggregate of numerous observations. It gives one condition where you want several; so that you cannot judge of individuals, but you may of national peculiarities; because it is probable that the convolutions and other circumstances will be similar in the same nation. We may say, therefore, that *cæteris paribus*, phrenology is true; because in the case we have supposed, the *cætera* will be *paria*.

The horizontal posture seems to assist thought, by retarding the flow of blood

through the brain, and thus nervous matter is secreted. Hence people, when they are puzzled, are told to "go and consult their pillow." Thought is most active when the pulse is regular, the heat of the surface natural, and the chymification perfect: and in all cases in which the expirations preponderate over the inspirations, as after exercise, or taking food in the evening, and under the influence of exciting passions. It is most energetic in the young and in females, and in persons of a choleric or a sanguine temperament. The exercise of thinking seems favourable to the vigour of thought, probably by increasing the secretion of nervous matter in the brain.

VOLUNTARY MOTION.

I. *Motions subservient to Respiration.*—Few persons have more than two octaves in the compass of their voice. Persons may learn to sing, as well as to speak or to dance; but they are generally disgusted with their maiden efforts. In producing a musical shake, the larynx moves rapidly up and down. Barclay says that seven pairs of muscles may make sixteen thousand combinations. But he mentions fifteen other pairs of muscles, which co-operate with the muscles of the larynx; and these will make millions of millions of different combinations. (The exact number is seventeen trillions, five hundred and ninety-two billions, a hundred and eighty-six millions, forty-four thousand four hundred and fifteen.) Hence the innumerable varieties of tones which may be produced by these different combinations. A difference of the three hundred and forty-fifth part of an hair's breadth in the opening of the rima glottidis, will make the difference between a true and a false note.

In the howling ape, the ventricles of Galen are very complicated. Some apes have the voice like a flute, while others whistle. Birds have two larynges; the upper of which (answering to the lips of the human subject) tempers the notes of the lower. Hence the extent and flexibility of the voice in birds. It appears in them to be a combination of singing and whistling; and the men who imitate birds, probably do so by combining the actions of the larynx with those of the lips. The voice is proved to exist in the lower larynx; for it remains after the trachea has been opened.

Below the class of reptiles, animals have no voice at all. The noise made by

grasshoppers is produced by striking the wings together; that of gnats and flies, by their friction of their wings in their sockets; and that of beetles by their wings striking the air.

The organ of voice resembles many musical instruments; but, like the rest of the organs of the body, itself must be its own parallel. The use of the thyro-aretenoid muscles is to stretch the vocal cords; that of the oblique and transverse aretenoid muscles, is to close the rima glottidis; and that of the anterior and posterior crico-aretenoid, is to open the rima. In speaking, the larynx forms the vowels, while the consonants are formed by the mouth. The muscles of the voice are the first to feel the effects of inebriation. Hence I have heard of people who had test-words, if they could not pronounce which correctly, they thought it time to leave their cups. Galen was the first to show that the voice came from the larynx; for previously to his time it was thought to come from the heart. Whispering is performed during inspiration, as well as during expiration; so that it does not require previous gulps of air. Hence it is chosen by weak patients. A good series of experiments might be made, on the sound of a musical snuff box in different gases.

II. *Motions subservient to Digestion.*—Tortoises have no teeth. They masticate with the continuous horny lining of the mouth. The teeth of the rest of the reptiles, as well as the teeth of fishes, are designed more for holding and lacerating, than for masticating. Teeth consist of bone, ivory, and enamel. In the herbivora, the enamel of the teeth dips into their substance. The teeth of the hippopotamus have no bone, and therefore they are preferred for making artificial teeth. The ornithorinchus (like many fishes,) has teeth on the palate, as well as in the jaws. In order to ascertain whether a jaw has belonged to a carnivorous or to a herbivorous animal, examine the condyles, and see if they admit of more than a hinge-like motion. If the jaw be broad, and furnished with grinding teeth, you have evidence of its having belonged to a herbivorous animal. The reason why a second set of teeth is necessary, is probably because teeth are required to be of so hard a texture as to be incompatible with their growing larger, in order to correspond with the increased size of the animal.

Catarrh is sometimes fatal to an infant, from its not being able to breathe while

sucking. Deglutition is seldom prevented by the shortness of the frenum linguæ; and if the latter be cut too much, the tongue may fall backwards over the glottis, and strangle the child. It is said that female slaves sometimes destroy themselves in this way, when labouring under nostalgia, and when deprived of all other means of destruction.

III. *Motions subservient to Sensation.*—In all exciting diseases, the nostrils are dilated, by the action of the levator labii superioris aëque nasi. In all depressing diseases, on the other hand, the nostrils are contracted, from the partial paralysis of the muscle we have mentioned. In the natural state, when the levator palpebræ is paralyzed by sleep, the orbicularis palpebrarum remains closed like the other sphincters. In tetanus and palsy, the eyes are often partially closed both during sleep and the waking hours. Under the influence of voluptuous feelings, the levator palpebræ is partially paralyzed, and gives a languishing expression to the eye, as is seen in the paintings of Hebe. The oblique muscles of the eye are probably involuntary.

IV. *Motions of the Body in general.*—Many corallines are stationary. Some animals are moved by the wind, and others by the waves. These animals have no locomotion. The muscle, though called a fish, belongs to the gasteropoda, like a snail. In the cephalopoda, as the *sæpia*, the arms or legs project from the mouth. The branchopoda make use of their gills to effect locomotion. The oyster, if it has any motion, can only leap by suddenly closing the shell, and thus projecting itself.

The legs of insects (which include cray fish, lobsters, crabs, &c.) are very perfect. All the winged insects have six legs; of which four are attached to the thorax. The caterpillar is said to have more than four thousand muscles. In the class of insects wings first appear. It is considered by some, that they are only transformed bivalve shells, with gills (or stigmata) under them; and that the wing-flaps are analogous to the opercula of fishes. In some kinds of fish, the gills pass into fins. All these are examples of unity of organization.

The structure of bones may be illustrated by that of beams. If a weight be hung on a beam, supported at both ends, the upper part resists by its non-compressibility, and the lower part by its cohesion, while the middle is almost

neutral. In bones, the middle is filled up with a light substance. In the thigh-bone, all the fibres of the head send towards the lesser trochanter, upon which the weight of the body falls. The same disposition of fibres is observed in other parts of the body. Duhamel's theory about the bone being formed in layers from the periosteum, is wrong; for in twenty-four hours all the bones of a young pig may be impregnated with madder. A story is told of an Irishman who, wishing to have his bacon in alternate streaks of fat and lean, fed his pig well one day, and starved it the next. Many young birds have no air in their bones, although they fly; and the ostrich and cassowary have air in them, although they do not fly. The wrist of the carnivora moves in every direction, whereas that of the herbivora has flexion only. In fishes the caudal vertebrae have long spinous processes, so that there cannot be any motion upwards and downwards to any great extent; but the lateral motion is very free. In the crocodile, on the contrary, the cervical vertebrae have long lateral spines, which prevent motion in that direction, so that the animal cannot turn its head without turning its body. In many animals the clavicle and scapula are amalgamated, so as to resemble a rib. This is the case with reptiles and cartilaginous fishes.

If a well-proportioned man holds out his arms horizontally to their full extent, on each side, the distance from the tips of the fingers of one hand to those of the other, will be equal to the height of his body. The pubes is midway from head to foot. If he stretches out his legs, as well as his arms, he will stand within a circle, of which the navel is the centre, and the hands and feet touch the circumference.

The muscles at the back of the neck are very strong, owing to the situation of the foramen magnum (at which the fulcrum is situated), and the shortness of the lever with which the muscles act, and which, therefore, requires the muscles to be very powerful, in order to maintain the head in the erect position. In quadrupeds the foramen magnum is still farther back; and the lever, therefore, is so very short, that they cannot maintain an erect position long. Osseous fishes have no muscles for moving the head; and they are very inconsiderable in cartilaginous fishes. In reptiles the motions of the muscles are very remarkable. Tortoises, for instance, project their head by mus-

cles from the dorsal shield, and retract it by means of the longus colli muscle. Of all animals, birds have the best muscles of the neck, and the freest motion of the head.

In order to resist the tendency in young persons to stoop forward, the best way is to place weights on the head, for in resisting this, the muscles of the back get stronger. On the same principle, in order to make horses lift their feet well they are shod with heavy shoes. A steel spring, if quite straight, resists a force applied to both ends, notwithstanding its elasticity; and when it yields, it is with a jerk. In order to avoid this, the spine is curved. The advantage of this arrangement in the lumbar region is very great. It forms the segment of a circle, and therefore there is no jar in running, stopping suddenly, or any violent motion; for the impulse is divided among several bones.

The ribs in some animals become wings, and they are the organs of locomotion in serpents and some lizards. The tail of a dog falls from the relaxation of the muscle which upholds it. In quadrupeds the latissimus dorsi and the pectoralis major are inserted low down in the humerus, so that the bone is quite hidden by them. This gives them a much greater lever power than in the human subject. A similar arrangement obtains in the posterior extremities. In paralysis the extensor muscles are more affected than the flexors, as being the weakest, and least able to bear the abstraction of power. It is to be cured by a splint on the opposite side, to prevent the flexors from always acting; for the extensors will not recover their power, if they are kept constantly stretched. In a post-chaise the horse which carries the postilion pulls better and with less fatigue than the other, because the weight is a substitute for muscular action. The weakest horse should carry the postilion. A farmer told me, he put a bag of flour on the back of a weak horse which he employed in a mill.

The pectoral muscles of birds weigh more than all the rest of their muscular system. Birds fly lower in damp weather, because the air is then rarer. In the horse, the semi-membranosus, the semi-tendinosus, and the biceps, are inserted so low in the leg, as almost to conceal the calf.

The human foot is flexed by two muscles, but is extended (as in raising the body on the foot) by six. In perform-

ing this motion, the muscles act with a lever of the second kind. The best-formed statue of the human frame will not support itself. A man, when standing upright, supports himself by muscular effort; but he soon "stands at ease," from muscular fatigue; and the old statues are all drawn in this attitude. Weakly children lounge too much, which gives rise to permanent distortion.

In favour of the biped theory of man, may be urged the situation of the nostrils, the axis of the eyes, the situation of the foramen magnum, the want of a ligamentum nuchæ, the breadth of the chest and of the pelvis, the difference of the extremities, the direction of the joints, and the different structure of the hands and feet. A child goes first on all-fours, because the muscles of the spine and the neck are not sufficient to hold up the back and the head. Horses go to sleep standing, for it requires no muscular effort for them to stand; and a statue of a horse will stand alone. Birds likewise sleep in the erect position; but in them it does require a muscular action, though not a muscular effort. It is done by means of a tendon, which leads from the foot, and passes over the back of the knee-joint; so that the weight of the body puts this tendon on the stretch, and fixes the claws round the perch. Sitting requires but little muscular action; and this was said by one author to prove that man was destined to a life of contemplation. But man is not always contemplating when he is sitting, or when he is lying on the back, which requires no muscular exertion at all. Shakspeare calls bowing a "jutting out of the bum," because we cannot bow without protruding that part.

It is said that the extensors of the leg will bear double the weight of the flexors, but that the latter have most power, because they are inserted a little lower down. When the foot is extended, it may be rotated, but not when it is flexed; so that here we have flexibility and firmness in the same joint. It is absurd to tell a person to make his toe first touch the ground in walking. It is contrary to physiological principles; for coming down on the heel first prevents a shock to the frame. We stand on an elastic arch, the points of support of which are the heel and the ball of the great toe. The foot has likewise a transverse arch.

LECTURES ON SURGERY,

BY

JOHN HUNTER, F.R.S.

[Having lately published the biography of John Hunter in this Journal, and determined to place his original and important discoveries before the world, through the medium of a Medical Periodical, we now proceed to redeem our promise. It must be scarcely necessary for us to observe, that it has long been regretted that the style of the author is often very obscure and inelegant, in consequence of the defects of his early education; and, on this account, it is deemed advisable to improve such defects without injuring the author's meaning or conclusions. The original phraseology will, however, be adopted, unless when it admits of doubt, or requires repeated perusal to comprehend it. There can be no second opinion as to the merits of the splendid discoveries of John Hunter, which are universally admitted throughout the civilised world; but it is hoped that a record of these discoveries in a cheap form will prove serviceable to all classes of medical readers. Influenced by this conviction, we now submit them to the medical public.]

Introductory Lecture—Plan of the Course—Preliminary Observations on Matter.

Mr. Hunter was wont to commence his lectures as follows:—

It is not my intention in these lectures to give the opinions of former writers, which may be found in their works, but I shall give you the result of my own observation and experience. I do not mean to assert that all I shall say in this course will be entirely new, and that none of my opinions or observations have not been already published; for there are many facts too obvious to have been overlooked in the most ignorant days of physic. In this course I intend to include some of the most important and interesting parts of surgery, more particularly those subjects on which I have had opportunities of making some new, and I hope useful observations, so as to place our Art, in many respects, in a new point of view; and as some of my ideas, as well as the arrangement of my subject, are new, consequently some of my terms must also be new, for two different ideas cannot be

expressed by the same words. That my opinions are correct, appears to me most likely, from their having in some measure stood that trying test, *time*, as well as having been adopted by others, which is one of the strongest proofs of their correctness. My terms will, I hope, be found expressive of what I mean them to define, which also appears evident from their having been adopted in many recent works on surgery. My lectures are not a regular course, but rather an explanation of what appears to me to be the chief principles of the Art of Surgery, so that by comparing and reasoning on known principles, my pupils may be enabled to act as the occasion may require.

I shall suppose you already acquainted with the anatomy or structure of the human frame, and must now inform you, that a knowledge of the healthy and diseased actions which constitute the principles of our Art, are not less necessary to be understood than the principles of the other sciences; unless the surgeon should wish to resemble the Chinese philosopher, whose knowledge consisted only of facts. In that case, our science must remain stationary, until fresh facts improve it. European philosophers, however, reason from principles, and thus they can predict facts before they arise. The greatest attention should be paid to facts; but too many crowd the memory without any advantage. Their chief use is to establish first principles; by these we learn the causes of diseases; and, without a knowledge of the causes of diseases, a man cannot be a good surgeon.

Surgeons are too often satisfied with observing the effects only; but in studying diseases we should understand not only the effect, as inflammation, suppuration, &c., but also the cause of that effect. Without this knowledge, our practice must be very confined, and our remedies very often injudiciously applied, since, in many cases, it will be necessary, if possible, to prevent the effect. In the bite of a mad dog, for example, the disease may be prevented by the removal of the bitten part; and in the venereal disease, as in cases of chancre, we must not only know how to cure it, but also to prevent its effects on the constitution, which is done by the internal use of mercury. We may, on the contrary, wish to increase the effects, which cannot be done, unless we know the cause; in many cases, where we cannot prevent the effect, nor afterwards remove, diminish, or increase it with advantage, our better

plan is to change to some other, which we can more easily remove; as, for instance, by converting the venereal into common inflammation. When the disease is already formed, we ought to understand the modes of action of the body and its members, by which they endeavour to relieve themselves from disease, as well as the power they have of restoring themselves to health, and we should know the best means of assisting those powers. If these prove insufficient, we are to judge by the attending symptoms and circumstances, when an operation may be necessary, and how far the condition of the constitution is favourable for it; the last is often an exceedingly difficult question to decide, and in some instances exceeds our present knowledge. I have seen a patient die in a few hours after the excision of a small tumour from the arm, and another by the removal of one from the abdomen; a third by castration; and within these two days, I assisted at an operation for fistula in perinæo, where the patient died in sixteen hours after. All these patients were previously in apparent good health. The cause of death in these cases, and the peculiar circumstances of constitution that render operations thus dangerous, will perhaps never be well understood. I consider this part of surgery, namely operations, to be a reflection on the healing Art; it is a tacit acknowledgement of the insufficiency of surgery, and seems to me like an armed savage, who endeavours to obtain by force what a more refined and cultivated man would attain by stratagem. No surgeon should approach the victim of his operation without a sacred dread and reluctance, and should be superior to that *popular eclat* generally attending painful operations, often only because they are painful.

My object in lecturing is not pecuniary gain; for the time I devote to my lectures would be more profitably employed in extending my connections and enlarging my practice. I have seen as much practice, and made a more extensive collection of diseased preparations than perhaps any man in Europe. By these preparations I find that the morbid appearances correspond with the opinions I have formed of the pathology of the diseases which they illustrate. After having been ten years engaged in the profession, in 1761 I entered the army. From my observations and experience while in the service, I am enabled to give my opinions on gunshot wounds, which rarely occur in civil prac-

tice. In the year 1768 I was solicited to become a teacher of anatomy, but I now rejoice that I did not comply, as my attention would necessarily have been too much engaged to allow me to cultivate surgery, as I have since done. Besides the necessity I should have been under of reading would have prevented my forming habits or established modes of thinking. In the years 1772, 1773, and 1774 I had frequent opportunities of giving my opinion in private, and have had always the satisfaction of being heard with candour. Since I have commenced my lectures, I have frequently found my opinions quoted in numerous works, and in some, even my very language, as adhesive and suppurative inflammation, &c. But my chief inducement to lecture is, that it is of the greatest advantage to a man to put his thoughts in writing; he can never tell how much he knows until he arranges his knowledge, and then he finds how defective it is; hence it is that almost all authors of any consideration in medicine have been public teachers.

I shall begin my present course of lectures with the physiology of the animal œconomy in its normal or healthy state. I shall afterwards describe the pathology, or physiology of disease, which is the perversion of the natural actions of the animal œconomy. Amongst the latter, I shall first treat of the most simple or natural accidents or diseases spontaneously arising; next of the means of restoration. On the latter subject I shall be particularly full. The first of these is adhesive inflammation, or as it is commonly called, healing by the first intention; next of inflammations tending to suppuration, granulation, and cicatrization. I shall afterwards consider the specific diseases, as locked jaw, scrofula, &c.; then the poisonous or malignant diseases, as venereal disease, cancer, &c. But before I shall commence the proper business of the course, I must call your attention to the properties of matter in general, and to that of organised beings in particular.

Animate and inanimate matter.

I must request your close attention to the subject under consideration; I must be a little abstruse in the present lecture, which I intend as an introduction to all animal matter. Before we attempt to give a definition of an animal, it is necessary we should understand the properties of that matter of which an animal is composed; and to give us a clear idea of animal matter we must know the properties of common matter. We should other-

wise apply our ideas of common matter, as being most familiar to us, to animal matter, an error we should carefully avoid, and hitherto a very common one. Matter is demonstrable by our senses alone; if a man had never seen light, he could not, from any description, form an idea of it; if he had been always deaf, he could have no idea of sound; if he had no touch, nor taste, nor smell, if he were without sensation, which is easily conceivable, he would have no idea that there existed such a thing as matter. Again, it is from matter alone that we come to a knowledge of our senses; so that it is from their reciprocal effects we have the only proof of the existence of either.

An animal, then, must be so composed as to be susceptible of impression; this impression consists of an alteration in the parts impressed. Matter must make the impression on us before we are sensible of its existence. Matter, however, is in itself only an abstract idea; it is not the matter itself, but some of the properties that belong to it, that make an impression on our senses, as sourness, heat. When we see a man, it is not the matter of the man that makes the impression, but the light which he reflects; this light the eye has the power of conveying to one point, so as to give a determinate shape on the organ of vision. The impression made on our eye, by a body exterior to us, exactly similar to touch, is the act of seeing: it is an impression made of a given figure, and every part of the body might be made able to see as well as the eye; for instance, a refracting glass was placed before my skin, so that the image should be thrown on my body, of the same shape as that which is exterior, if my sense of feeling was so very delicate as to distinguish this shape, it would give me the same idea as seeing. A drum has no sound in itself, but it has the power of putting the matter of the air into action, which produces the idea of sound by its impression on the organ of hearing; yet the sense of touch would appear to offer the greatest contradiction to the above statement. Touch, however, arises from the resistance of matter, which alters the form of the part touching, and this alteration causes feeling. If sensation arose from the matter itself, and not from its resistance, we ought to have as many kinds of sensation as we have of matter; but our sensations correspond with the different properties of matter, not with the different kinds. But to return to our subject: all that composes this globe of

the earth is called matter, and is most probably formed of some few substances differing in specific properties from each other, but which in different combinations produce a very great variety, and consequently produce a great variety of sensations in us. Matter, thus compounded, is apparent to our senses in some one of the following states—a state of solidity, fluidity, or vapour. Solidity appears to be the natural state of matter; fluidity and vapour seem to imply a kind of force, particularly vapour.

Attraction is one of the most remarkable properties of matter; of this there are several kinds.

First. *Elective attraction*, or the disposition in all matter to unite with some particular kinds of matter rather than with others, and form a compound with them that would seem almost homogeneous. Elective attraction can only exist when bodies are in a state of either fluidity or vapour; it is one of the most refined properties of common matter, producing new compounds by a species of regeneration, but destroying the old by the same action; and this property is given to matter to insure the variety that exists in the regular solids and fluids that compose the world.

Secondly. The attraction of cohesion is an increase of the same attraction, by which bodies are brought into closer approximation, and kept in one mass. When a body is so subdivided as to be reduced to its constituent particles, that is to a state of fluidity, still each particle has its centre of gravity, on which it may be said to move. A fluid then would seem to be a body reduced to its original parts, from the attraction of cohesion being destroyed; each particle, however, has its centre of attraction or gravity. As the centre of the globe attracts every particle of matter that is on it, so every mass of matter, simply as matter, has a centre of attraction, by which it can bring bodies to it, or keep them in contact with it; thus if we were to drop some quicksilver, and that it did not meet any resistance, it would assume a globular form, not from the attraction of cohesion, but from the attraction of gravitation. Where, however, the attraction of cohesion is but slight, as in fluids, this will not take place unless there is some affinity, as between acids and water, alcohol and water, &c. Oil and water, when in a state of fluidity, will not unite by this kind of attraction.

The attraction of cohesion also gives rise to other general properties, such as

figure, magnitude, &c. These are the properties that render bodies suitable for mechanics, but there are others necessary; a clock may, for instance, be correctly made, yet it will not go until we bring in the aid of the pendulum, or coiled spring. Thus we observe something like the life of mechanics, which is not matter, but a property of matter; what is simply mechanical, that is inert matter, must have, as it were, a soul to put and continue it in motion. When these properties have their full effect, they become, by causing other effects, the regulators of the whole mass, with regard to motion, space, &c.

These are some of the properties of common matter. I am not able to determine how far repulsion is a universal principle, but I suspect it is not so general as the others; that there is such a principle is evident, because without it neither fluidity nor vapour could take place. Heat may, probably, be the great repulsive principle; at least, it counteracts attraction, and causes repulsion when diffused among the particles of matter. Thus the matter of the globe is, in general, regulated by a property so constituted, that it cannot err in its common actions.

There are other properties belonging to matter, which are more extended than those just mentioned; it undergoes changes not in the least connected with, or arising from them, and its properties are therefore entirely different, appearing, as it were, an anomaly in the combination of matter. Its continuance by preparing matter similar to itself is effected by changes entirely different, which produce the animal and vegetable, or organic portion of the world. I shall consider the properties of these in my next lecture.

THE ANATOMIST.

THE PELVIS,

Is formed of the os sacrum, os coccyx, (both of which bones have been already described) and the two ossa innominata.

OS INNOMINATUM,

Consists in early life of three bones, the ilium, ischium, and pubis. We shall describe each of these bones separately.

OS ILIUM.

Situation, upwards and outwards in

regard to the pelvis, forming the upper part of the acetabulum, and the lower lateral part of the abdomen.

Body, constricted, forms the upper and outer part of the acetabulum, joining the pubis anteriorly, and the ischium posteriorly.

Ala, expanded, offers four aspects, viz., the dorsum, which is rough posteriorly for the gluteus maximus, and presents two semicircular lines for the gluteus medius and minimus muscles; also a nutritious foramen—the venter which forms the iliac fossa, in which also is a nutritious foramen—the rough articular surface for connection with the side of the sacrum, and a small portion smooth and immediately above the sciatic notch, which enters into the formation of the true pelvis.

Processes.

The *Crest* which forms the upper border of the ala.

The *anterior superior spine*, which terminates the crest anteriorly.

The *anterior inferior spine*, immediately above the acetabulum.

Both spines are separated by a *notch*.

The *posterior superior spine*, which terminates the crest behind.

The *posterior inferior spine*, separated from the former by a small notch.

The *Ileo-pubic eminence*, marks the union of this bone with the following.

OS PUBIS.

Situation, forepart of pelvis, and internal part of acetabulum.

Body, forms the internal and superior part of the acetabulum.

Horizontal ramus, passes inwards to meet the opposite ramus.

Symphysis pubis is formed by the union of both horizontal rami.

The *angle* is formed by the horizontal ramus turning down to form the symphysis.

The *tuberosity* is about three quarters of an inch external to the angle.

The *crest* is the small upper transverse portion of bone between the angle and tuberosity.

The *obturator groove* is situated upon the under surface of the horizontal ramus.

The *descending ramus* passes backwards and outwards to meet the ascending ramus of the ischium, it bounds the thyroid hole, and by the divarication of the two descending rami, the *arch* of the pubis is formed.

THE ISCHIUM.

Situation, lower, outer, and back part of the pelvis.

Body, forms the outer and back part of the acetabulum; immediately beneath this cavity is a groove for the tendon of the obturator externus muscle. The anterior thin edge of the body assists to form the thyroid hole, the posterior to form the sciatic notch.

Spine, projects backwards and inwards, and bounds the great sciatic notch inferiorly.

Tuberosity, the thickest part of the bone, on which we rest when sitting. Between this process and the spinal is a pulley-like surface, for the tendon of the obturator internus muscle.

Ascending ramus, turns forwards, upwards, and inwards, and joins the descending ramus of the pubis; it bounds the thyroid hole by its outer thin edge, and the lower aperture of the pelvis, by its thick one.

ACETABULUM,

Is formed by the union of the bodies of the ilium, ischium, and pubis; the ilium forming less than two-fifths; the ischium more than two-fifths; and the pubis the smallest part. It presents an articular surface for the head of the femur, and a rough surface inferiorly and internally for the ligamentum teres, where also this cavity is shallowest, and its border deficient.

SUPERIOR EXTREMITY,

Consists of the shoulder, the arm, the forearm; the wrist, and the hand.

THE SHOULDER,

Is formed of the clavicle and the scapula.

THE CLAVICLE.

Situation, from the semilunar notch in the upper piece of the sternum, to the acromion process of the scapula.

Figure, curved like the italic *f*.

Sternal end, thick, presenting a triangular articular surface; its edge is rough for ligaments.

Body, cylindrical towards sternum, flat and expanded towards its acromial end. Upon its under surface are a ridge for the rhomboid ligament, a rough tubercle for the coraco-clavicular ligaments, and between both a groove for the subclavian muscle, in which groove is found the nutritious foramen.

Acromial end, rough and flattened, passes over the coracoid process to meet the acromion scapulae, with which it articulates by a small oval surface.

SCALPULA.

Situation, upper and back part of thorax, extending from the second to the seventh rib.

Figure, triangular.

Costæ or edges. The superior or cervical is the shortest and is interrupted by a notch for the suprascapular nerve; the inferior or axillary is next in size, and is the thickest; the posterior or vertebral is the longest, and is also called the base of the scapula.

Angles. The superior posterior angle is acute and prominent, the inferior angle is thicker and rounded, and the anterior angle has connected to it the neck of the bone.

Costal surface, or subscapular fossa, is slightly concave and divided by three or four lines, which run from above obliquely downwards and inwards.

Dorsal surface is divided unequally by the spine, which thus gives rise to the fosse.

Spine arises at the vertebral margin, and proceeds forwards, becoming more elevated, and terminates in the acromion, which surmounts the shoulder joint and articulates with the acromial end of the clavicle by a small oval surface.

Supraspinous fossa, situated above the spine, is deep, and presents a nutritious foramen; it lodges the supraspinatus muscle.

Infraspinous fossa, larger, irregularly concave and convex, affords attachment to the infraspinatus muscle, the teres minor muscle, and by an inferior rough surface, to the teres major muscle.

Coracoid process overhangs the inner and upper part of the glenoid cavity. This process has a crooked appearance, and gives attachment to the pectoralis minor, the short head of the biceps and the coraco-brachialis muscles, also to ligaments.

Glenoid cavity articulates with the head of the humerus is shallow and oval form, being broader below, and giving attachment by its upper narrow part to the long head of the biceps muscle.

Neck is the contracted portion of the scapula immediately behind the glenoid cavity; it gives attachment to the capsular ligament of the joint.

OS HUMERI.

Connections to the scapula above and radius and ulna below.

Head forms a small section of a large sphere, is smooth and covered with cartilage in the recent state.

Neck, a slight contracted line, rough for the attachment of the capsular ligament. It is united to the shaft by an obtuse angle.

Tuberosities exist at the junction of the shaft with the neck. The largest is posterior, and affords attachments to the supraspinatus, infra-spinatus, and tees minor muscles; the smallest being anterior, more prominent, and giving attachment to the subscapular muscle.

Bicipital groove is between both tuberosities, lodges the long bicep tendon, and affords attachment by its anterior margin to the pectoralis major muscle, and by its posterior margin to the latissimus dorsi and teres major muscles.

Shaft is rather twisted, the upper extremity cylindrical, the lower flattened upon its external and central aspect, is a rough portion for insertion of the deltoid muscle and upon the minor side of the bicipital groove is a slight rough line for the insertion of the coraco-brachialis muscle. The nutritious foramen is directed downwards towards the elbow joint.

Internal condyle is prominent and sharp, affording attachment to the pronator and flexor muscles, and to the internal lateral ligament.

External condyle is less prominent, but descends nearer the elbow joint, and gives attachment to the supinator and extensor muscles, and to the external lateral ligament.

Articulating surfaces. First, a small round *head*, situated externally and nearer the anterior than the posterior part of the bone, for the radius. Second, the *trochlea* or pulley-like surface placed internally for the ulna; being much below the level of the *head*, so as to give the articular surfaces an oblique direction from above downwards and inwards.

Coronoid fossa at the fore part of the trochlea to receive the coronoid process in the bent position of the forearm.

Olecranon fossa at the back part of the trochlea, to receive the coronoid process in the extended position of the forearm.

ULNA.

Situation at the inner side of the forearm.

Upper extremity articulates with the humerus and radius.

Olecranon process, posterior forming the projection of the elbow, is the highest point of the bone, and by its superior border gives attachment to the triceps muscle; beneath this it is smooth for a bursa mucosa.

Coronoid process, anterior and inferior to the olecranon, is smaller than it, and gives attachment to the brachialis anticus muscle, the flexors and pronators of the forearm and to the internal lateral ligament.

Lesser sigmoid cavity, oval and receives the side of the head of the radius.

Greater sigmoid cavity has its long axis from before backwards, is directed in the centre by a transverse line and by a vertical ridge into two lateral portions, is bounded above by the olecranon process, and below by the coronoid process.

Shaft presents three surfaces and three edges; the anterior surface affords attachment to the flexor profundus muscle, and is pierced by the nutritious foramen, which is directed upwards. The posterior gives attachment to the anconeus muscle and to the exterior muscles of the thumb; the internal is subcutaneous for its greatest extent. Of the edges, the external is the best marked, and gives attachment to the interosseous ligament.

Carpal extremity slender and rounded, presents the *head*, which by its side articulates with the radius, and by its carpal aspect with the fibro-cartilage of the wrist-joint; also the *styloid process* at its inner margin, which by its apex gives attachment to the internal lateral ligament of the carpus, by a depression of its root, to the fibro-cartilage; and posteriorly it presents a groove for the tendon of the flexor carpi ulnaris muscle.

RADIUS.

Situation, external to the ulna; it is also shorter than that bone.

Head, a superficial circular cavity, articulating above with the humerus and laterally with the ulna.

Neck an inch in length, narrow and rounded, and terminating in the

Tubercle, a prominent process into which the tendon of the biceps muscle is inserted.

Shaft, triangular, by its anterior surface affording attachment to the flexor pollicis proprius, and pronator quadratus muscles, by its posterior convex surface to the supinator brevis muscle, and extensor muscles of the thumb; its exter-

nal surface being round and convex, and rough near its centre for the pronator teres muscle. The inner edge of the shaft is sharp for the attachment of the interosseous ligament, and the nutritious foramen upon the anterior surface of the shaft is directed upwards.

Carpal extremity expanded, gives attachment by its anterior edge to the anterior carpal ligament; upon its posterior edge is a shallow groove at its ulnar side for the extensor communis digitorum and indicator muscles, a second more externally, narrow and oblique for the tendon of the extensor secundi inter nodii pollicis muscle, and a third more external than the last for the tendons of the extensores carpi radiatis longior and brevior. Upon the radial edge of this extremity is the mark of the passage of the extensor ossis metacarpi and the extensor primi internodii pollicis muscles.

Styloid process, prolonged on the outer side of the bone downwards, giving attachment to the external lateral ligament of the carpus.

Sigmoid cavity on the inner border of the carpal extremity for articulation with the ulna.

Carpal aspect presents two articular surfaces, divided by a slight elevation; the external being triangular for articulation with the os scaphoides, the internal square for the os lunare.

CARPUS.

This part consists of two rows of small bones, four bones in each row, placed between the forearm and metacarpus. It is convex and rough upon its dorsal aspect, and concave upon its palmar aspect, where the vessels, nerves, and tendons of the flexor muscles are situated; towards the radius and interarticular cartilage of the wrist, it is convex; towards the metacarpus it presents articular surfaces for the metacarpal bones.

FIRST ROW.

Os Scaphoides.

Situation, on outer and upper part of the carpus, next the styloid process of the radius.

Articulations, with the radius above, with the trapezium and trapezoides below, and with the lunare and magnum internally.

Os Lunare.

Situation, between the scaphoides and cuneiforme.

Articulations, with the radius above,

with the magnum and unciforme below, with the scaphoid externally, and with the cuneiforme internally.

Os Cuneiforme.

Situation, at the internal and upper part of the carpus between the lunare and pissiforme.

Articulations, with the lunare externally, with the carpal fibro-cartilage above, with the unciforme below, and upon its palmar aspect with the pissiforme.

Os Pissiforme.

Situation, upon the inner and palmar aspect of the cuneiforme.

Articulation, by a circular small surface with the cuneiforme.

SECOND ROW.

Os Trapezium.

Situation, between the scaphoides and metacarpal bone of the thumb.

Articulations, with the scaphoides above, with the metacarpal bone of thumb below, and internally with the trapezoides and side of the metacarpal bone of the index finger.

Groove, upon its palmar aspect for lodging the tendon of the flexor carpi ulnaris muscle.

Os Trapezoides.

Situation, between the trapezium, magnum, scaphoides, and metacarpal bone of the index finger.

Articulations, with the scaphoides above, the trapezium externally, the magnum internally, and below with the metacarpal bone of the index finger.

Os Magnum.

Processes, head, neck, and body.

Situation, between the scaphoides and lunare, and the second, third, and fourth metacarpal bones.

Articulations, by its head with the scaphoides and lunare above, by its base with the second, third, and fourth metacarpal bones below, externally with the trapezoides, and internally with the unciforme.

Os Unciforme.

Situation, between the cuneiforme and metacarpal bones of the ring and little fingers.

Articulations, with the lunare above, the magnum externally, the cuneiforme internally, and below with the fourth and fifth metacarpal bones.

Process, a hook-like process upon its palmar aspect.

METACARPUS.

This part consists of five long bones placed between the carpus and the fingers.

Bases, irregularly flattened for articulation with the second row of carpal bones, with rough surfaces for the attachment of ligaments.

Heads, convex, and rounded for articulation with the first bones of the fingers, and affording attachments for the capsular, transverse, and lateral ligaments.

Bodies.—The *first*, for the thumb is the thickest and shortest; the *second*, *third*, and *fourth* present on the dorsal aspect of each a prominent line, which bifurcates towards the head; the *fifth* presents an oblique line on its dorsal aspect, which divides it into two surfaces. The third is the longest.

FINGERS.

The fingers are composed of three phalanges, except the thumb, which has only two.

The metacarpal, or first Phalanges, are five in number, their bases presenting oval concavities for the heads of the metacarpal bones; their anterior extremities are convex from before backwards, and concave from side to side, to articulate with the second phalanges.

The Middle, or second Phalanges, are four in number, and smaller than the first; their bases present pulley-like surfaces, to form a ginglymoid joint with the first phalanges, and at their anterior extremities resemble the first.

The Ungueal, or third Phalanges, are five in number, and the smallest. By their bases they form a ginglymoid joint with the middle phalanges; and their extremities are convex upon their dorsal aspects for the support of the nail, whilst their palmar aspects are irregularly tuberculated for the extremities of the fingers.

The Sesamoid Bones are sometimes absent. In general two are to be found between the metacarpal bone of the thumb and its first phalanx, and one or two at the corresponding joint of the index finger.

ATROPHY,

OR

DIMINUTION OF THE HEART.

Laennec had found the heart of a man aged fifty-five years as small as that of a child of twelve years. Bouillaud observed the heart of a woman aged sixty-one as small as that of a child of twelve years old. In some cases the substance of the left ventricle was no more than a line and a half in thickness. In other cases the heart loses a third, a fourth, or one half of its natural size.

Signs of Atrophy of the Heart.—The symptoms of atrophy are the reverse of those of hypertrophy already described (See p. .). The pulsations of the heart are small, concentrated, the bruits which accompany them are feeble, the shock of the heart is felt with difficulty or not at all by the hand, or it is much weaker than natural, and there is scarcely any dullness of sound in the precordial region. The pulse is small, thready, and hard in *concentric atrophy*, while it is soft, feeble, and full in *aneurismal or excentric atrophy*. The movements and sounds are extremely feeble and distant on auscultation. The first sound is very valvular, and clear in some cases, but when the disease is extreme, it is inaudible. Atrophy of the heart may exist in general emaciation, but the latter condition may be extreme, and hypertrophy present. I have observed cases of atrophy in which the ventricle was wasted to the thinness of bank paper.

Causes.—The causes are local or general. Among the local causes are long continued compression of the heart by effusion of fluid, by tumours, or any other mechanical cause, and contraction of the coronary arteries by disease, as ossification, calcareous, or cartilaginous deposits. The general causes are different morbid states, or different conditions which impair the nutrition of the whole body; chronic diseases which induce great emaciation, such as phthisis, cancer, affections of the brain, liver, spleen, uterus, &c. &c. typhoid enteritis, eruptive fevers which do not prove fatal for two or three months, &c.

Treatment.—Nutritious aliment,—every thing calculated to improve the general health; and the alleviation of diseases in other parts which cause general emaciation, so far as this can be accomplished. Atrophy of the heart must be considered incurable.

AUGMENTATION AND DIMINUTION OF ABSORPTION OF THE SEROUS AND CELLULAR TISSUES OF THE HEART.

PASSIVE HYDRO-PERICARDIA, AND PASSIVE OEDEMA OF THE CELLULAR TISSUE OF THE HEART.

Passive hydro-pericardia does not differ essentially from the active species in anatomical characters.

The anatomical characters of œdema of the heart are a tremulous gelatiniform matter in the cellular tissue, which, on pressure, is found to be a transparent, serous, limpid, yellowish, or greenish yellow serosity. The infiltrated tissue is opaline, or of a dull white colour, as if it had been macerated in water for some time.

There is no sign by which we can positively recognize this disease of the heart during life; but we may suspect its existence in persons affected with passive general dropsy, which may extend to every part of the cellular tissue, which is the base of every tissue and organ in the body.

Causes.—The causes of dropsies are numerous obstacles to the course of the blood, whether mechanical, physical, or vital.

The obliteration of the cardiac veins is a cause of passive hydropericardia, or œdema of the heart. A varicose state of the coronary veins and their branches, and a difficulty of disgorging themselves into the right auricle, was the cause of the disease in persons treated by M. Bouillaud.

Hydropericardia may be also caused by rupture of a serous cyst, or hydatid, or by blood effused into the pericardium.

Treatment.—Depletion, diuretics, purgatives, and the usual remedies for dropsy will be required.

PNEUMO-PERICARDIA. — HYDRO-PNEUMO-PERICARDIA.

The pericardium may also secrete gas, which is termed *pneumo-pericardia*, and when combined with fluid, *hydro-pneumo-pericardia*.—(Bouillaud.)

In this disease the pericardium resonates on percussion like an inflated bladder, and if its parietes are incised the gases escape with a whizzing noise.

The causes of this disease are as yet unknown, and the diagnosis is drawn from the tympanitic and splashing sounds in the region of the pericardium. Laennec sometimes discovered pneumo-peri-

cardia by the clear resonance under the sternum, or by the sound of fluctuation caused by the beatings of the heart, and by strong inspirations. In a case of hydro-pneumo-pericardia, M. Bricheteau heard in the pericardial region a bruit or sound similar to that of water agitated by the wheel of a mill, which was evidently caused by the alternate motions of the heart. We must not mistake the similar sounds elicited from the same region when the stomach is partly distended with fluids and gas, and when it encroaches on the heart, as in dyspeptics, giving rise to palpitations and other functional derangements of the heart, which are often mistaken for structural or organic diseases. Nervous women, and the delicate of the other sex, are very liable to such derangements, but the distinction can be made by every scientific practitioner.

NEUROSES, OR NERVOUS AFFECTIONS OF THE HEART.

There is no class of disorders so common as those of the action of the heart, and yet it is a most remarkable fact, that the best authors who have treated on diseases of this organ, have scarcely noticed them. Corvisart has not even named them; Laennec has devoted only a few pages to their description; Andral has not described them, Hope has nearly overlooked them, and even Bouillaud himself allots but five pages to their consideration. The best account of them with which I am acquainted is by Dr. Calthrop Williams of Nottingham, though by no means a complete one.*

The nerves of the heart, in common with all others in the body, are liable to functional disorders or derangements of the principle of their power, termed innervation, but which are not appreciable, as well as to structural or organic diseases. These disorders of function comprise all unpleasant sensations or feelings, from the slightest to the most intense pain, spasm, or neuralgia; and may be divided into three principal classes—those of augmentation, diminution, and irregularity of the phenomena dependent on

* "Practical Observations on Nervous and Sympathetic Palpitations of the Heart, particularly as distinguished from Palpitation the result of Organic Diseases; to which are prefixed some General Remarks on the Use of the Stethoscope and Percussion in Diseases of the Heart and Lungs."—London, 1836.

the nerves of the heart. M. Bouillaud has proposed the terms of *hyperdynamia* of the heart to augmentation of the movements of the organ; *adynamia* to the diminution of these movements; and *ataxodynamia* to irregularity of the same movements. I should prefer more accurate terms, as cardio-hyperdynamia, cardi-adynamia, cardi-ataxodynamia.

Nervous palpitations of the heart may exist without any organic lesion, may continue for an indefinite period and be cured; or they may be sympathetic of organic diseases of the heart, as inflammation, hypertrophy, atrophy, &c.; or of diseases of the brain, the lungs, stomach, digestive and other abdominal organs; or of those in any other part of the body. Both classes are often troublesome, and the former very unnecessarily alarming, and too often supposed to be organic and incurable. This was well observed by the late truly eminent Dr. Baillie, as appears by his posthumous work:—"There are in truth few phenomena which puzzle, perplex, and lead into error the inexperienced (and sometimes the experienced) practitioner, so much as inordinate action of the heart. He sees, or thinks he sees, some terrible cause for this tumult in the central organ of the circulation, and frames his portentous diagnosis and prognosis accordingly. In the pride of his penetration, he renders miserable for a time the friends, and, by his direful countenance, damps the spirits of his patient. But ultimate recovery not seldom disappoint his fears, and the physician is mortified at his own success." Such mistakes are still too often made by those who do not employ auscultation and percussion; and there are as yet but a small proportion of medical practitioners, unless those educated within the last few years, who employ these means of diagnosis.

Mr. Wardrop has well observed in his valuable work,* that nervous affections of the heart must precede structural diseases. "It is quite evident that such changes of structure must be preceded by a train of phenomena, and by a series of lesser disturbances in the function of the heart, the detection of which will enable us to apply remedial means with

a probability of achieving the same advantages, as in the treatment of diseases in other organs." It is therefore manifest that it is most important to study the nervous or functional derangements of the heart, which are of common occurrence; and also to distinguish them from organic or structural diseases.

NERVOUS PALPITATION OF THE HEART.

The term nervous palpitations of the heart is given to those frequent strong and tumultuous movements which agitate the heart in individuals, who have no appreciable material or organic lesion of this organ. These movements may be transient or momentary, or they may continue for a long time. They sometimes augment the force or impulse of the heart, and enable the practitioner to see and hear them at some distance from the sufferer; and the patients themselves sometimes hear them when they repose on the left side. Palpitations are sometimes accompanied by a slight and transient bruit de soufflet, which disappears as soon as the heart becomes quiet. They are also attended by a feeling of sinking and anxiety, which is difficult to describe, which patients refer to the region of the heart or pit of the stomach, and often designate "a sinking at the heart." In some cases there is a tendency to fainting fits or syncope, and a pulsation at the pit of the stomach.

Causes of nervous palpitations.—The causes of nervous palpitations are extremely numerous, such as the various mental emotions, and every kind of muscular exertion, which must more or less accelerate respiration and the circulation of the blood.* Every cause that produces debility excites the disorders under consideration.

Persons of a nervous temperament and

* Mr. Wardrop has established the existence of three most important functions connected with the circulation of the blood, which had hitherto been overlooked.

"1. That the muscles, besides being the active organs of locomotion, perform the important office of increasing the quantity of arterial, as well as of venous blood within the cavities of the heart.

"2. That the lungs regulate the supply of blood to the heart, so as to prevent congestion within the heart's cavities; and

"3. That the subcutaneous veins performing the office of a reservoir, prevent congestion of blood within the pulmonary vessel." *Op. Cit.*

• On the Nature and Treatment of the Diseases of the Heart, with some New Views on the Physiology of the Circulation, by James Wardrop, M.D., Surgeon to the late King, Lecturer on Surgery, &c. London, 1837.

those of both sexes subject to hysteria, hypochondriasis, melancholy, epilepsy, and general nervous disorders, are very liable to palpitations. Vivid mental emotions, joy, grief, anger, sadness, fear, anxiety, &c., the acts of weeping, sobbing, crying, laughing, and swinging, intellectual labour induce them—so that the chief causes are mental or cerebral excitement, irritation or depression. Debility, during the convalescence of fevers or other acute diseases, or that caused by chronic or slow diseases, severe loss of blood by any kind of hemorrhage, inordinate natural discharges, abuse or long use of purgatives, spare or unwholesome diet, the abuse of spirituous, vinous, or fermented liquors, want of sleep, long continued anxiety and distress, close confinement, intense study, dissipation and debauchery, excess of venereal pleasures, and more particularly onanism, as well as excessive sexual intercourse, are causes of palpitations and irregularities of the heart. Persons subject to anemia, or great pallidity from loss of blood by abortion,* or any other cause, or to chlorosis, which is very analogous to anemia, are very liable to nervous palpitations of the heart.

Chlorotic girls are often supposed to labour under organic diseases of the heart when there is only functional or nervous disturbance of the organ. They complain of palpitations, pain in the region of the heart, head-ache, difficulty of breathing, pain in the left side over the spleen, &c.; are bled, leeches, cupped, blistered, &c., when the opposite treatment ought to be employed, as tonics, quina, strychnia, chalybeates, iodide of iron, &c. Such persons may have transient bruit de soufflet, or bellow's sound of the heart, and a musical sound in the crural and carotid arteries, which is termed bruit de diable, from its resemblance to the whizzing of a double top, used in play in France, and termed diable. Palpitations are also ascribed in other cases to organic diseases of the heart, but the diagnosis cannot be mistaken by any one who will read with care the preceding account of such diseases. Persons of a nervous temperament and full habit are also very subject to palpitations. They complain on going up stairs, or any other ascent, or raising the arms, carrying

or lifting any weighty substance, using any exertion. They are most affected in cold, moist, or foggy weather. They experience pain or numbness in some part of the left arm, throbbing in the head, fulness in the neck, sense of strangulation in the throat, fluttering of the heart, or as if it was grasped or compressed, and sometimes its motion is termed rolling, thumping, strong then weak, irregular or intermittent. It is maintained that when the action of the heart is intermittent, there is a complete though instantaneous suspension of the contraction of the organ; and when the pulsation is irregular, that there is only a partial contraction. Thus Laennec described *real* and *false* intermittence of the heart's action.

Persons who suffer from spinal irritation are also very liable to palpitation, and I have counted the pulse 160 in such cases. There are also pains extending from the spine to the abdominal and thoracic organs, to the neck, shoulders, head, limbs, and, by nervous sympathy, to every part of the body. The respiration is difficult, or easily rendered so, on any slight exertion or mental emotion; and the pressure of the stays on the chest, round the waist, or lower part of the spine, is intolerable. Pressure on the affected part of the spine has suddenly induced pain in the chest, cough and palpitation; and the disease is very common in large towns to girls and young women, from the age of fifteen to twenty-five years, and in some to fifty. I have fully described it elsewhere.* Lastly, nervous palpitations are very common at the cessation of the menstrual function, and to women labouring under diseases of the womb, ovaries, breasts, or any chronic complaint. They may be slight, transient, and intermittent, like all other nervous disorders; and they recur more frequently in proportion as the heart becomes more irritable; but they do not produce any serious alteration of the health for a long time, though I have known them when caused by terror to be speedily followed by hypertrophy of the heart. They are most troublesome after vivid mental emotions and muscular exertion, though they are sometimes most

* The Cyclopædia of Practical Surgery, edited by W. B. Costello, M.D. Part I. April 1837. Art. Abortion, by M. Ryan, M.D.

* See Manual of Midwifery and Diseases of Women and Children. Third edition, plates, 1832. By M. Ryan, M.D. See also Teale on Neuralgia. Tate on Hysteria. Addison on Uterine Irritation. Williams on Nervous Palpitation, &c.

distressing when the body is in a state of repose, as during the first part of the night, and often prevent sleep for several hours. They are also occasionally accompanied by a sensation of internal agitation or fluttering in the head, chest, or abdomen, and there is often a copious evacuation of urine. They are least troublesome when the person is in the open air and taking exercise; a fact attested by most nervous women.

Diagnosis.—The diagnosis is very difficult in some cases (Andral, *Dict. de Med.* en vol. 21), though easy by means of percussion, auscultation, vision, and touch, by which the heart can be measured with *geometrical* precision, and its organic diseases determined, so that nervous palpitations can be easily distinguished from those accompanying considerable organic lesions of the heart. (Bouillaud.) In nervous cases the sounds of the heart's contractions, though clear, are not heard loudly over a great extent of the chest. Nervous palpitations are generally without impulse; the head of the auscultator, &c. is not sensibly elevated as by the increased motion and shock of hypertrophy. They are also known by the absence of the signs which accompany organic diseases of the heart, and more frequently affect the auricles than the ventricles, and the right auricle than the left. (Professor Home.)

Treatment.—In plethoric individuals, general and local bleeding in the region of the heart, by leeching, cupping, and then the use of tartarized antimony, digitalis, hydrocyanic acid, colchicum, antispasmodics, and a proper use of purgatives. In such cases, low diet, repose, and quietude of mind and body, will be necessary. Counter-irritation by antimony or blisters, or an anodyne plaster over the region of the heart, as one of belladonna, opium, hyscocyamus, or conium, will be very beneficial. In delicate, nervous, or chlorotic persons, tonics, chalybeates, warm or cold baths, shower baths, change of air, a nourishing diet, improvement of the digestion and general health with moderate exercise, form the indications of the treatment. Blood-letting is generally injurious, and I have known the worst consequences produced by it. Chlorotic girls complain of headache, palpitations of the heart, and agitations in many or most parts of the body; and these symptoms will be aggravated by bleeding, purging, low diet, &c. In such cases there is anemia, or, a universal pallidity of the whole surface

of the body, or a want of red blood, which is not to be supplied by depressing measures.

In nervous palpitations from mental emotions, tranquillity of mind is indispensable, and moral means alone can remedy moral palpitations. Nervous palpitations are often aggravated by the fear of organic disease of the heart; but if the medical practitioner convinces his patient of this error, a cure will, in most cases, be very speedily accomplished.

NEURALGIE OF THE HEART.

Neuralgic pains in the heart are transmitted from the nerves of the organ to the phrenic, intercostal, pneumo-gastric, brachial, and cerebral plexuses, &c., and not only cause derangement of function in all the parts supplied by these nerves, but by sympathy in all parts of the body. It is most probable that certain cases of nervous asthma, angina pectoris are simply neuralgic affections; and these are generally relieved by powerful sedatives and anti spasmodics, as in cases of nervous palpitations.

Spasm of the Heart is described by Laennec, though considered an imaginary disorder by Bouillaud, who states that there is no positive fact to attest its existence. But I see no reason why the heart should not suffer from spasm as well as all muscular organs.

LIPOTHYMIA—NERVOUS SYNCOPÉ.

Swooning, lipothymia, and syncope are only degrees of the same nervous affection—a diminution of the innervation of the heart. The highest degree, which is syncope, is really a momentary paralysis of the heart.

The phenomena of complete syncope are similar to those of sudden death, and only differ by life being restored in the majority of cases, though in some rare cases real death takes place. It is a most important physiological point in criminal cases to distinguish between apparent and real death, or whether contusions or injuries were inflicted before or after death, and one which I have fully considered in another work.*

A person about to be attacked with syncope, experiences an indescribable distress, or feeling of faintness; the eyes become dim, and covered with a kind of

* A Manual of Medical Jurisprudence and State Medicine. By M. Ryan, M.D. Second edition.

film; there is a sense of singing or buzzing in the ears, the countenance and lips are pale, the mind fails, and the body is covered with a cold perspiration; the limbs fall as if inert masses, and are unable to support the body; the person falls on the ground or floor; the respiration and pulse disappear, and no sign of external life remains: "*it is momentarily eclipsed.*" Nevertheless, the functions sooner or later return, and life is restored.

Syncope does not continue, in general, longer than a few seconds; but, in some cases, it persists for several minutes. It is not to be confounded with that species of syncope characterized by want of intelligence, which may continue for several hours or days, because the complete absence of the beatings of the heart could not continue so long a time without causing real death.

The feeling of weakness and sinking which usually precedes syncope is not always felt; for some persons experience a feeling full of charms, of sweetness, and almost ravishing delight.

Causes.—The causes of syncope are very various and opposite; as joy and grief, love and hatred, &c. Syncope may be the effect of severe physical pain in any part of the body, or of vivid mental emotions, of sensations produced by the sight of certain objects, by certain sounds, odours, &c. Certain poisons, as narcotics, hydrocyanic acid, septic miasms, or odours; and loss of blood by depletion or hemorrhage, induce the disorder under notice. In fine, great obstacles to the circulation of the blood also suspend the action of the heart, and cause syncope.

Treatment.—When syncope is purely nervous, as in nervous women, there is seldom any danger; the sufferer ought to be placed in the recumbent or horizontal position, on sofa, bed, or on the floor, fresh air admitted, cold water sprinkled on the face and neck, ammonia, hartshorn, burnt feathers, æther, eau de Cologne, vinegar, and a thousand other means in popular use, will be sufficient to restore animation.

The other indication will be to remove the exciting cause, and to improve the general health. (See DYSPEPSIA, HYS-TERIA, HYPOCHONDRIASIS, &c.)

IRREGULARITIES AND INTERMITTENCES OF THE PULSATION OF THE HEART.

In my history of the PULSÆ, I described the natural action of the heart, and its morbid states in the various dis-

organization of the centre of the circulation, and perhaps in all other diseases. I have now to observe, that the irregularities and intermittences of the pulsations of the heart often arise from the causes which produce nervous palpitations, and will be relieved by the same remedies. They may also depend on organic diseases of the heart, as already described. It is worthy of notice, that the pulse at the wrist and heart may be irregular or intermittent during health, become regular during acute disease, and return to its former condition during convalescence or recovery. For a full disquisition on this subject, see the essay already cited.

M. R.

(To be continued.)

The London Medical AND Surgical Journal.

Saturday, April 29th, 1837.

THE QUEEN'S HEALTH.

We regret to state that her Majesty's health has been for a long time past in a delicate condition; and has of late assumed rather a serious character. Besides occasional attacks of hæmoptoe, she has never been free, for some years past, from cough. Until lately she has been entirely under the care and direction both of German and English homœopathists, on whose system she had placed the most perfect confidence and reliance. The exclusion of the *pures*, more particularly of the indefatigable President of the College of Physicians, on such a momentous occasion, has given rise to just cause for serious vexation and distress amongst the Fellows; and, much to their credit, several meetings of the College were held to discuss the propriety of legal measures being adopted by that learned body, to repress so public a demonstration of irregular practice in the case of one of

the highest Personages of the State. If indeed the College of Physicians be empowered by the legislature to punish **IRREGULAR PRACTITIONERS** in medicine, there could not have been a better opportunity for the learned President and his Council to have come forth in a manly and straight forward manner, and prosecuted the *homœopathic* pretenders, and thus not only claimed their just rights and high privileges as a body incorporated by charter "for the prevention of quackery," but they might have been the indirect means of rescuing the valuable life of an illustrious Personage. This striking fact of the President and Council of the College of Physicians having allowed so favourable, nay, indeed, so palpable an opportunity to pass by unnoticed, of inflicting the utmost rigour of the law on those practitioners, to whom they had not granted one of their *licences*, entitles us to presume that on no future occasion will they ever attempt to enforce their long tottering rights and privileges; and that they will permit *all* kinds of practitioners, regular and irregular, to follow their calling unmolested. We are well aware that some of the more enlightened members of the medical profession are of opinion, that no enactments of the legislature, however judicious, can ever suppress quackery. The case of her most gracious Majesty affords the most incontrovertible evidence of the impossibility of the Government interfering in matters of this description. It ought, indeed, to be recollected, that it is not "the lower orders" of this community who more particularly suffer from quackery; it is the highest and most enlightened members of society who foster and patronize empiricism.

If this opinion of the impossibility that any interference of the legislature be incompetent to suppress **QUACKERY**, we fear

that there is little hope of the efforts of the **BRITISH MEDICAL ASSOCIATION**, however vigorous, being at all likely to arrest the numerous evils which the community suffer from irregular practitioners. All that the Association can ever effect is by upholding and improving the condition of the regular practitioner, to produce a corresponding depression in the estimation of the *irregular*; but if we consider the constitution of society, we must be convinced, that from the reputation of **QUACK DOCTORS**, and the cognizance and protection which the law gives to **QUACK MEDICINES**, it is impossible to conceive how the legislature, far less any association of medical practitioners, can reasonably expect to prevent a system of things, which, at this time in particular, has been receiving the sanction and countenance of one of the most illustrious individuals of this great empire.

THE LATE MR. VANCE.—MEDICO-LEGAL QUESTIONS.

The circumstances which attended the death of this eminent surgeon, must render every tribute to his memory acceptable to his professional brethren; and it is impossible for them not to feel deeply for his fate, as none who are engaged in the practice of medicine are ever exempt from being the victims of a like accident.

Mr. Vance was a native of Ireland, and received the chief part of his medical education in Dublin; after which, in 1792, he entered the British Navy. After having served at sea for nearly fifteen years, and having deservedly acquired much reputation for his talents and zeal in the service of his country, he was appointed surgeon to the Naval Hospital, at Haslar, and afterwards to the Naval Hospital at Painton. Having a second

time served in the Haslar Hospital for a few years, he was, in 1819, appointed surgeon to the Royal Hospital at Greenwich; and after devoting his services in that institution, which is so magnificent a monument of our naval glory, for nearly five years, he retired from the public service, and settled in this metropolis. The high character which he had acquired during his long services in the British Navy, at once secured to him the countenance and support, not only of all those who had derived the benefit of his professional services as a naval officer, but all their friends and connexions flocked to him, seeking his opinion and aid, from the hour of his commencing the practice of his profession in London. From that period until the time of his melancholy death, he continued to enjoy an unusual share of public confidence, which, with economical habits, enabled him to leave not less than the sum of £100,000 to his surviving family. Though Mr. Vance has not left us any records of his useful and successful labours, yet it is well known to those who were personally acquainted with him, that he availed himself of the great opportunities which he had of acquiring knowledge. He paid particular attention to anatomy, which enabled him to accumulate a very valuable collection both of natural and diseased specimens. Mr. Vance expired in the 67th year of his age, leaving a widow and large family to deplore his loss.

The mode by which Mr. Vance met with his untimely end, and which, singular enough, befell, no long period since, M. Pelletan, of Montpellier, is one of serious consideration, and involves medico-legal questions of the highest interest to society at large. It will be recollected that it was first announced through the public press, that an insane person, on whom Mr. Vance was in attendance,

escaped the surveillance of his keeper, and struck the deceased with such violence, as to precipitate him down a flight of stairs; which he received a fatal injury on his by head. The patient was immediately conveyed to a lunatic asylum, but on whose authority did not appear. A coroner's inquest was held upon the body of the deceased; and, though the whole of the details of the evidence never reached the public eye, enough transpired to let it be known, that a different opinion existed in the minds of the jury, as to whether the deceased had been *forcibly* thrown down stairs, or had been *accidentally* overthrown by the accused. But previous to the coroner's inquest, there appeared a strange document in all the daily papers, in the form of a letter, from a pupil of the deceased—a Dr. Willis, who does not appear to have been an eye witness, purporting to give an *explanation of the mode* by which Mr. Vance had met with his death; and endeavouring to give the public an impression that in place of the deceased having been attacked and forcibly tumbled headlong down stairs, the perpetrator of the deed had only *accidentally* encountered the deceased on the stairs, and in rushing past him, caused the mortal injury. There was something so unusual in a document of this kind appearing in *all* the newspapers, before a coroner's inquest was held, or any legal investigation of the case took place, that it is impossible not to review the whole of the proceedings connected with the lamentable event, without contemplating the legal questions which they involve—questions, as we have already said, of vital interest to the community. No evidence has been yet adduced that the perpetrator of the deed was a *lunatic* in the eye of the law, to constitute which, it is imperative that the patient should have been declared to be an insane person on

the authority of the "certificates of two legally competent medical practitioners," and that he should have been placed under the care of proper keepers.

MEDICAL EVIDENCE—GREENACRE'S CASE.

We transcribe the following strictures on the Medical Evidence in Greenacre's case from a cotemporary (*British Annals of Medicine*) which agrees with our own remarks in our last number, as will appear to our readers more strikingly after a perusal of the preceding article in this Journal.

"The evidence goes to prove that the parties were on the very best terms within a few hours of the horrid tragedy; the surgeon gave it as his opinion (but we cannot agree with him) that the fatal blow which destroyed the right eye was produced by the fist. Here there was evidence directly in favor of the prisoner. The jury ought not to have brought in a verdict of murder. The circumstantial evidence only led to an inference of manslaughter. A sack was borrowed, but the murderer required three sacks or bags!!! It is true the verdict of the jury has turned out to be correct, but this is only an accident. The evidence did not lead to the conclusion at which they arrived. The evidence of the gentleman who examined the contents of the stomach is by no means satisfactory, judging from the various newspaper reports. Evidence was adduced by the prisoner's counsel to prove that the murdered woman had been inebriated. The evidence states that the fluid in the stomach had a *spirituous* smell. 'With regard to the *spirituous* smell, I came to the conclusion that it was neither *whisky* nor *rum*, and that it was *gin*, to the best of my belief. I satisfied myself of this by a chemical test.' What the *chemical test* was we are not told. If this gentleman has discovered a *chemical test* for *gin* in such minute quantity as must have occurred in this case, mixed with the heterogeneous fluid matter of the stomach, he has made no contemptible discovery, and will confer no small benefit on his Majesty's revenue if he will only reveal it in the proper quarter. Again we are told, 'The quantity of spirits I should say was not sufficient to cause intoxication.' How much spirit was present we are not told. It is, however, absurd to pretend to judge of the occurrence of intoxication before death by an examin-

ation of the contents of the stomach a fortnight after death. Dr. Christison could not detect the smell of *whisky* in the stomach of the woman Campbell who died by the hand of the notorious Burke, although she was intoxicated with that liquor half an hour before her death, and the body was examined 38 hours after death. The apparent decision (although in reality great inaccuracy) of the evidence we have just considered, must have had its effect upon the jury in prejudicing them against the prisoner, in so far as it seemed to make out a proof that the woman could not have been intoxicated. The chemical evidence is therefore highly reprehensible, and ought not to have been delivered before a court of justice, especially when the life of a fellow-creature was implicated. We speak of the evidence which we have seen in print. These remarks may appear severe, but they are dictated only by a sense of public utility and a high sense of moral feeling."

PHARMACY IN DUBLIN.

In our Dublin contemporary a most interesting paper is given by Mr. Moore, Apothecary, with a view to estimate the use made of the principal medicines by the most eminent physicians and surgeons of Dublin since the year 1780, to the present time. No person was better qualified to undertake a task of this kind than Mr. Moore; for not only has the establishment over which he presides, and which was commenced by his grandfather, uninterruptedly enjoyed the most extensive support and confidence of the profession and the public, but the writer possesses a persevering industry, added to talents of no mean order. Mr. Moore divides the entire time into three equal portions, and from each of these he takes twelve thousand prescriptions, marking the frequency with which each medicine occurred in them. The general results of the tables thus constructed are as follow.

"Emetics in the first period were given ten times as often as in the second, and twelve times as often as in the last. Formerly, they were given invariably at the onset of a fever, as, according to the prevailing theory of Cullen, they took off the spasm of the extreme vessels. Enemata were prescribed during the last forty years somewhat less than one half as often as during the first twenty. The period when they were most seldom ordered was about the time when Dr.

Hamilton's purging practice was introduced. Their use is now becoming more frequent. Local bleeding has made a gradual and steady progress. Blisters and warm plasters have diminished, and the latter have been partly superseded by stimulating liniments, and other modes of counter-irritation. Tartar emetic was given constantly as an emetic in the first period: but, except as an emetic, it is met with most frequently in the third. Kermes mineral was formerly much used in pneumonia: it has ceased to be employed, but the antimonial and James's powder have increased. The total number of the preparations of antimony is nearly equal in each of the three periods. Opium has kept its ground steadily: its camphorated tincture has fallen almost into disuse. Hyoscyamus is more used, owing to the extract being commonly prescribed in conjunction with blue pill. In the first period the red Peruvian bark was used generally, and in powder. After that, the infusion and tincture of the pale bark; and now sulphate of quinine has in great measure superseded all. Epsom salt has been but recently commonly employed, its place having been formerly supplied by Rochelle salt, sal polychrest, and the sulphate of soda. Nitre has fallen into comparative disuse. Blue pill was found seventeen times in the first period, thirty-nine in the second, and 156 in the third; owing to Abernethy's recommendation. The use of mercurial ointment in frictions has much diminished. Jalap has decreased, and rhubarb increased. Ipecacuanha is used much more at present than formerly. Fifty years ago blisters were seldom dressed with simple ointment, or allowed to heal soon; basilicon or an ointment of trifolium melilotus was employed."

The Editors of the British Foreign Medical Review, v. R. Carmichael, Author of the Essay on the Origin and Nature of Tuberculous and Cancerous Diseases.

TO THE EDITOR OF THE LONDON MEDICAL AND SURGICAL JOURNAL.

SIR,—In the last number (vi.) of the above Journal appears a review of the above Essay; upon which I beg you will insert a few observations, as, happening to be present at the reading of it to the Medical Section of the British Association,

I must admit that the novel views it contained made the impression upon my mind that the Author, to use a homely phrase, "had hit the right nail on the head," when he attributed an independent vitality to those masses of animal matter which contribute to that class of diseases hitherto deemed malignant and incurable, and aptly compared them to the parasitic fungi which grow upon the decaying surfaces of trees and vegetables.

I shall consider the Reviewer's objections *seriatim*, passing over the first page, which consists of a preliminary discourse of truisms that nobody will deny, and obviously meant as a rhetorical flourish to the cut and thrust attacks which follow.

The first assault upon our Author is that he has taken his views respecting the nature of tubercle almost exclusively from the phenomena which he supposes it to present in a *single* organ, viz. the lungs, and then he proceeds a little further on to observe, "that if Mr. Carmichael will forget what he has imagined he has learned from his examination of tubercles of the lungs, and look at this morbid product in the pelvis of the kidneys, ureters, fallopian tubes, cavity of the uterus, and other hollow organs, or in the artificial cavities, such as those formed in bone, in *lumbar abscess*, or in *lymphatic glands*; in all of which situations this substance occurs in masses of various extent, and presenting all the characters which pathologists regard as constituting the *type* of this product, he will agree with us that he has hitherto been strangely deceived; for he will perceive here nothing like 'semi-transparent grey vesicles,' or 'regular compact masses like grains of shot.' He will only perceive a cheesy looking substance of various consistence, having no *elementary* form, even when examined in the microscope. It is merely in juxtaposition with the surface which had secreted it, or lies detached from it like so much foreign matter or refuse, which the lining tissues could not appropriate for the purposes of nutrition.

To these objections I merely reply, that in various parts of Mr. Carmichael's Essay he not only considers tubercles of the lungs, but those of most other organs, and even in a brochure necessarily so brief, he introduces several instances of their presence in the viscera of the abdomen and other parts of the frame. The cheesy looking substance of various consistence, without elementary form, Mr. Carmichael contends only appears in

tubercles after they have passed into transmutation, similar to those which hydatids are known to undergo; and until Dr. Carswell can account for the regularity and formed appearance of the grey semi-transparent tubercles, so well described by Laennec, as well as those other solid ones which are compact, rounded, insulated, medullary looking bodies, I positively deny the position that he has "satisfactorily demonstrated, that tubercle is an amorphous product, essentially composed of an unorganizable substance," consequently having "no form but that which is impressed upon it by the influence of the mechanical and physical condition under which it happens to be placed;" and when we consider that those regularly formed bodies have no connexion by means of vessels with the tissues in which they are found, I am inclined to an opinion directly the reverse of Dr. Carswell. According to Mr. Carmichael's views, tubercles, like hydatids, (acknowledged Entozoa) pass through various transmutations, in which they lose all figure and form; they also, by their increase spread into each other, so as to present the appearance of an amorphous product, such as may be found in the "pelvis of the kidneys, ureters, fallopian tubes, cavity of the uterus, and other hollow organs." Hydatids, when they pass into the solid state, lose all traces of their original form and organization, and actually become compressed and moulded into shapes dependent "upon the mechanical and physical condition under which they happen to be placed," and in the analogous transmutations which tubercles undergo we find a satisfactory explanation of the amorphous heterogeneous misshapen masses which they present in some instances, while the defined and regularly organized appearance which they display in others before transmutation is thus no less satisfactorily explained.

Mr. Carmichael certainly in no part of his Essay speaks of tuberculous matter being found "in lumbar abscess or in lymphatic scrofulous glands;" for he distinctly considers the curdy matter of scrofulous abscesses as altogether different from the brainlike substance of which tubercle and other morbid growths of a malignant character is so generally composed. The consideration of the identity of these substances belongs to Drs. Carswell, Clarke, Todd, and others of the Carswell school. Mr. C., however, while he states his dissent from this doctrine,

candidly admits that the scrofulous constitution is one predisposed to tuberculous formations. He says, "I have constantly observed that those persons who have suffered from scrofula in infancy and youth, are the most liable in mature and advanced age to cancerous complaints:" but, surely, this circumstance does not prove the identity of scrofula and cancer.

The Reviewer next charges Mr. Carmichael with committing "a serious mistake in not making a distinction between two things, the one possessing *vital properties* and the other a *distinct or separate animal existence*." Now I really cannot discover the serious mistake which is thus laid at the author's door. His object was to advocate the independent vitality of tubercles, and to prove that they had a separate existence from the animal bodies in which they grow, and not to show that they are a part and parcel of those bodies, "possessing in a low degree some vital property."

After the reviewer has found fault with what he terms Mr. Carmichael's definitions and anatomical descriptions of tubercles, which would appear to any unsophisticated mind not meant for either, but mere passing observations, expressive of his belief in their independent vitality and transmutation when their vitality ceases. The reviewer indulges his critical acumen in the following effusion: "Now although we think that we have already shown the fallacy of the definition and description of the anatomical characters of tubercles, such as we have quoted it from Mr. Carmichael's Essay, we cannot avoid stating that his definition is a mere assumption, which can derive no countenance from the anatomical characters of the supposed animal to which it is applied. He does not even afford us the satisfaction of telling us what means he employed to ascertain their anatomical characters. Indeed, he is not, as we have already said, very clear on this point; for he talks of their being semi-transparent vesicles or opaque vesicles, and concludes by saying, that they are in fact thickened vesicles or cysts; nay, he is determined to have them animals, whatever appearance they present, even should they resemble grains of shot; for, he adds, by way, we presume, of removing every possible objection, 'I do not see why their solidity should be an objection to their possession of an independent vitality.' It need hardly be observed, that such dubious language and such

loose reasoning is unworthy of serious consideration. A pathologist claims the attributes of vitality and independent existence for a thing which he cannot bring before our senses under any definite form! or, rather, which he represents as possessing no essential elementary *material character!*"

In order to answer this unfair and garbled representation of Mr. Carmichael's opinions and statements, I shall briefly subjoin what they manifestly are, as collected *passim* from his Essay.

The diseases under consideration Mr. Carmichael considers may arise either in the form of hydatids, or in that of a solid medullary substance. That in neither shape have they any communication by means of vessels with the parts in which they are embedded, as is proved by injection, but that both the one and the other are generally enveloped in a cyst or covering, varying in density from the consistence of a serous membrane to that of cartilage, which receives vessels from the surrounding tissues, and is, therefore, an integral part of the body infested by the parasite; and that this envelope serves the purpose of insulating, and at the same time restraining the growth and multiplication of the Entozooa which it surrounds.

In this plain description of the bodies for which Mr. Carmichael claims the faculty of individual existence, surely we have sufficient of "*definite form and material character*" to satisfy any mind but that of a prejudiced partisan, or a wilfully blind reviewer.

The next point in Mr. Carmichael's Essay discarded on by the reviewer, and appears of any consequence, is the observation that "as long as they (tubercles) retain life, they do not occasion any stimulus or disturbance in the parts in which they have their nidus to throw them off." This observation of the author's is illustrated by the well known fact concerning the guinea worm, (*vena medinensis*) that as long as this entozoon retains life, it does not excite inflammation in the solid tissues in which it is lodged, but when deprived of life, that it then, and not till then, gives the stimulus of an extraneous body, and thus excites that suppuration by which it is ejected. Mr. Carmichael did not say, that living worms do not excite pain, he could not have the hardihood and folly of contradicting the universal experience of mankind, nor could the reviewer have misunderstood him with any other object

than that of introducing a useless and vapid dissertation which fills nearly page 360, in order to show that intestinal worms and other parasites while alive may excite pain, convulsions, and even death. It is quite unnecessary to make any observation upon this gratuitous and common-place labour, as Mr. Carmichael never asserted the contrary.

The reviewer next enters into a long disquisition to show that Mr. Carmichael mistook the meaning of Doctors Carswell, Clarke, and Todd, when they argued for the identity of "*scrofula and tubercle*." They do not maintain, he continues, "*that scrofula is identical with tubercle*;" for scrofula implies the disease, tubercle its substantive product. Scrofula, or the tubercular diathesis, may exist without the presence of the latter. Hence we speak of scrofulous glands as indices or manifestations of the tubercular diathesis, but not as tubercles; although actual anatomical observation has shown that such glands, either *before* they have suffered much enlargement or inflammation, or *after* they have been for an indefinite period the seat of chronic inflammation, *always contain a greater or less quantity of tuberculous matter.*"

Now, in no page of Mr. Carmichael's Essay has he urged against these gentlemen that they argued for the identity of the "*Disease Scrofula*," with its substantive product Tubercle." This sample of stupidity could scarcely have originated in the brain of a disinterested Reviewer, but in pages 8, 9, 10, of Mr. Carmichael's Essay, we find quotations from the works of Doctors Carswell, Clarke, and R. B. Todd, stating their belief in the identity of tuberculous and scrofulous matter; and even the Reviewer himself, by the words in italics, has shown that Mr. Carmichael was not wrong in the obvious construction of the passages in question. And here I trust to be excused for stating, that in my humble apprehension Mr. Carmichael's view of the nature of tubercles in the lungs, accounts more satisfactorily for the phenomena of the disease and its incurable nature, than the doctrine that they are unorganizable scrofulous depositions. In his prefatory remarks we find, that so far from considering his essay on the subject as complete, he states his intention of following up the investigation "*by availing himself of every opportunity which offers of post mortem examinations of examining animals which die of tuberculous diseases, and of extending his experiments upon living animals, in order*"

to ascertain how far unhealthy regimen is capable of producing tubercles, and of learning, if possible, whether they are capable of absorption by a change to a healthy regimen, which engages the important question, whether or no tuberculous diseases admit of a cure; and he finally hopes that others, unbiassed by pre-conceived notions, will favour those views by pursuing the same interesting investigation." This modest announcement might, we think, have disarmed his Reviewer of a portion of the venom, when he accuses Mr. Carmichael of giving "incomplete and inaccurate views on a most important subject for the instruction of the profession."

"The only other misinterpretation," the Reviewer next urges, "on the part of Mr. Carmichael, to which we shall allude, is in reference to the influence of inflammation in the production of tubercle. 'How will Doctor Carswell reconcile,' says Mr. Carmichael, 'the two following passages. At page 267* we read as follows: 'Under such circumstances it would be absurd to ascribe the origin of tuberculous matter to inflammation;' and after arguing (continues Mr. Carmichael) the identity of scrofula and tuberculous diseases, we find, at page 259, the following observations: 'Inflammation of any organ may be followed by the deposition of tuberculous matter in that organ in the manner in which we have already explained. We have frequent examples of the subcutaneous glands of the neck, and submaxillary glands, becoming tuberculous after an acute attack of inflammation, although previously neither enlarged, indurated, nor otherwise diseased.' We are surprised that Mr. Carmichael should call upon Dr. Carswell to reconcile statements the meaning of which is so obvious, and so consonant with the doctrines which this pathologist entertains on the nature and origin of tubercles."

Surely it must be acknowledged by any one who understands the English language, that Doctor Carswell contradicts himself in these two quotations. But it is only fair to give the Reviewer's explanation of it. "Doctor Carswell has (he continues), we conceive, throughout all his writings on this subject, consistently maintained, and satisfactorily demonstrated, that it would be absurd to attempt to ascribe the origin of tuberculous matter to inflammation, whilst, at the same time, he has no less satisfactorily explained,

and, we think, beautifully illustrated, the manner in which this pathological state operates locally, as a *remote or exciting* cause of tubercular depositions. Believing, as Doctor Carswell does, that tuberculous matter is separated by a process of secretion from the blood, he considers that the *localization* of the disease, or *presence* of this substance in a particular organ, or portion of an organ, is not only frequently determined by the superintention of inflammation, but would not, in many cases, take place, had this local morbid condition not occurred. Hence he does not admit that inflammation is necessary to the formation and deposition of tuberculous matter, but that, as it gives rise to an accumulation of blood, and consequently to an increase of secretion, in the part which it affects, it is frequently followed by the deposition of tuberculous matter; that change of the constitution termed tubercular diathesis, *previously existing*, without the modifying influence of which, the products of inflammation would have been those by which it is characterised in other or ordinary circumstances, viz., coagulable lymph, or pus."

To this laboured explanation to reconcile two contradictory statements, I answer, that the influence of inflammation in causing peculiar depositions, which, on Doctor Carswell's own hypothesis, might take place equally well without it, is a mere assumption without proof, and contrary to every thing we know of the constitution of animals, either in health or disease. It is an assumption manifestly brought forward for the purpose of propping up a lame and impotent theory respecting the identity of scrofulous and tuberculous matters. Doctor Carswell might as well assert that the heterogeneous mass of which fungus hematodes is composed, is deposited on various organs at the same time, in consequence of a fungoid "diathesis" previously existing, but that occasionally inflammation will act as a "*remote or exciting cause*" of these depositions in a constitution thus predisposed.

Verily, Dr. Carswell had better, in prudence, seek a more able or skilful hand to extricate him, when he again happens to give two contradictory statements, or plunges on the horns of such a dilemma.

The next objection to our author is one of the greatest importance, because it is not a matter of opinion that is questioned, but a matter of fact. "Mr. Carmichael (continues the Reviewer) says that there is in every carcinomatous structure two distinct

* Cyclopædia Pract. Med., vol. iv.

substances. One is a hard cartilaginous mass, which admits of being injected; the other is of the consistence of brain, or a medullary substance, which does *not* admit of being injected. The latter I esteem the true entozoon, or parasite; the former, i. e. the cartilaginous part, I look upon as the barrier which the surrounding tissues throw up to insulate the parasite.

"We should like to know (says the Reviewer) what such pathologists as Andral, Cruveilhier, Lobstein, and Carswell, would say of this description of carcinoma;" and then, after overwhelming him with this host of authorities, proceeds to deny the accuracy of Mr. Carmichael's statements, and to pronounce them the very reverse of the fact, viz., that the cartilaginous part does not admit of being injected, while the medullary part does; nay, that so rich in blood is this substance occasionally, that it is almost as red as blood; and this not from hæmorrhage, but from the presence of the aggregated multitudes of the fine capillary vessels which constitute a part of its organization, and that medullary sarcoma, or fungus hæmatode, is as obviously organised as the brain or cerebral substance which it resembles."

This is a bold assertion of our critic, but since *he* screens himself under the mysterious and secret mantle of a reviewer I conceive that Doctor John Forbes, and Doctor John Conolly, editors of the British and Foreign Quarterly Medical Review, ought to call upon that scribe to show those preparations in which he has seen fungus hæmatodes, and the medullary substance of a cancerous mass injected, while the cartilaginous portion remained uninjected, rather than lie under the imputation of misleading the public respecting a fact of so great importance.

As I was present at the reading of Mr. Carmichael's paper, I recollect his showing several preparations of cancer to illustrate his view of the subject, since which time I have examined several collections of morbid anatomy, and every thing I have seen confirms me in the opinion that he is right, and, consequently, that the reviewer is wrong.

Having now pursued this wily fox in a fair sportsman-like manner through all his windings and turnings, till I have fairly run him down, I shall not make use of my indisputable power over him, but carefully bag him for future amusement, should the animal have strength and courage to afford us another day's sport. But to be serious, I shall, in his

own words, "take my leave of him; and if the tone in which I have treated him should appear to carry with it more than merited censure, I seek no other grounds of justification than those I have already offered, viz., the importance of the subject," and the necessity of exposing the selfish drifts of that numerous class of scribes who are always at hand, for a trifling consideration, or the mean desire of pleasing a patron, to pander their talents for the support of those who in their turn can afford them a lifting hand to ascend the ladder of professional reputation.

I have indicated sufficiently the gross partiality of this critic in his errors of commission. Now for his errors of omission. A fair reviewer, one who was anxious not only to do justice to the public, but to the author, would be happy to have it in his power to give the meed of his approbation to the latter whenever a fair opportunity occurs. But the critique in question is one extended mesh of censure, without a single word of approbation. Were I the reviewer, I should have seized with pleasure upon the opportunity of doing justice to an author, whose just rights were assailed by surreptitious attempts to rob him of his claim to priority of discovery. Thus Mr. Carmichael's views relative to the connexion of scrofula and derangement of the digestive organs, published in a work on that disease in 1810, have been filched from him without any acknowledgment, and even the subject treated under the following headings in which he had previously considered it: 1st, improper diet; 2nd, impure air; 3rd, deficient exercise; 4th, imperfect clothing; 5th, exenthe mata, all stated by him to be as exciting causes of that disease. Since that period those views have been enlarged and expanded upon by others, without any acknowledgment of the source from which the information has been derived. I would, however, *en passant*, advise the authors who borrow largely without acknowledging the debt, in future to take those liberties only with the dead, and not with the living; for the latter may, perchance, as in the present instance, lay claim to their legitimate property.

As the publication in which the review appeared is but young, not having as yet acquired the eagle flight and strength of older journals, I would, in the soft language of Mr. Junks, the boatswain, beg to insinuate to its editors, in the most delicate way in the world, that *it* may

neither acquire the strength or flight of its seniors, if it so soon begins to follow the polluted courses which only long established publications can venture to pursue with impunity, or at least without the dread of immediate punishment. I shall not farther imitate our friend, the boatswain's energetic habits of following up his *suaviter in modo*, by the *fortiter in re*, and inflict blows after flattering with blandishments; but merely suggest that whether Doctor Carswell's views or Mr. Carmichael's, are those founded in truth and nature, it signifies but little what the reviewer may do to the support of the one or the extinction of the other, for *magna est veritas et prevalebit*.

JUSTUS.

FAMILY CORRESPONDENCE.

Great Russell Street,
Oct. 18th, 1836.

My dearest Father,—I received your's of the 8th, and was delighted to find that my darling mother and all at Killballymacalogue were as well as when I left them. You cannot imagine the state of anxiety I have been in since I last wrote to you, about selecting the school and hospital to attend; and late as it is now in the first month of the season, I have only just entered. I hear, however, from every one that so long as a pupil does not pay away his money, there is no fear of his being refused to enter even if the season was half over, for they are all so very avaricious in this place. I have been to many of the introductory lectures, and have paid most particular attention to the inducements held out by the several speakers in recommending their school, so that I was on the point of entering to St. Bartholomew's Hospital School after hearing Mr. Lawrence's opening lecture; but keeping your advice, I thought it best to sleep upon the matter, and the following morning, having had the good luck to find the honorable Mr. Wakley at home, I consulted him; when you may judge my surprise upon his telling me, that Lawrence delivered the same lecture ten years ago, and has been in the habit of repeating it every year since, to his own knowledge; and besides, that his lectures were published in the *Lancet*, taken verbatim by his own reporter, Mr. McChristie, the best in Europe; and that Mr. Stanley, the surgeon, who has a great memory,

entertained a party after dinner, a few weeks ago, at his own house, by repeating verbatim more than half of Lawrence's introductory compliments to the students, and all the usual *palaver*. This at once decided me in having any thing to do with St. Bartholomew's.

I next day heard Dr. Charpie, at the Gower Street University College, but he was very nervous and agitated, and his confusion, together with a strong Scotch brogue, made me not catch half what he said. The little I did pick up, was to the effect, that "it was his first appearance in London, that he was engaged in Edinburgh by our friend, Dick Quain, to come up and supply the place of Professor Doctor Quain, who retired in disgust on account of some fraternal professional persecutions; that he would do his best, and that the best could do no more." There certainly was a great degree of honesty and earnestness about the Speaker's manner, notwithstanding his confusion, which strangely contrasted with a demonstration I heard in the morning from Professor Quain, upon the *os coccygis*. Upon the whole, I thought it best to look about me further.

Understanding that Mr. Howship the rectum doctor was to open the medical school at the Charing Cross Hospital by an introductory lecture at seven o'clock, P. M. I swallowed a hasty dinner at the Italian eating house, Cranborne Alley, near the hospital, which is a very respectable place to dine at, and where, although it costs something more, there is no danger of meeting low company, and found myself seated in the theatre with five other students, two of whom were apprentices of the notorious Mr. Van Butchell; there were also present Mr. Van Butchell himself, who is, I understand, patronized by Mr. Wakley, and three others of his fraternity. Immediately opposite to where I sat was a plaster-of-Paris bust, which I was told was a likeness of the director, a Doctor Goolding. A few minutes after the time Mr. Howship, accompanied by five or six others, made his appearance, and begged he would be excused from taking off his hat, as he had a bad cold, but I heard after, from an apprentice of his who sat next me, that he always got his hair curled for all great occasions of this kind, and being in a great hurry and confusion, the barber set fire to one side of his head, and singed nearly all the hairs off. I spoke to him after he had finished, and he certainly had a burnt smell. He very kindly asked

me home to tea, where I met the other officers of the hospital, and from the many inducements they held out to me to enter to the hospital practice, I did so, and paid my money. I enclose you a printed list of the fees for attendance at the several hospitals, and you will perceive the Charing Cross is very cheap, and I am also promised a dressership and house surgery without any additional fee. It was most fortunate I was not in a hurry to enter to a school when I first came to London, for the inducements held out by the Medical School of the Greville Street Free Hospital are so very great, and the fees so exceedingly small, that without hesitation I entered to it *perpetual*. The fee to everything, you will perceive, is only twenty-one pounds, and we are to have comparative anatomy in the summer, natural philosophy, botany, and clinical observations upon homœopathy, which is a new method of practice by which the greatest saving in drugs will be achieved: and the drugging system practice, which is very prevalent in London, completely done up. You will perceive that one of the lecturers is a *Cantab*, and the other an *Oxon*; all the *corruptionists*, as the hon. member for Finsbury calls them, are now tacking these titles to their names, in addition to the M.D., which marks them as being perfectly distinct from the learned and liberal individuals, who form the metropolitan university. I have only seen Mr. Wakley once, he must be a very great man, for it is impossible to catch him at home. I hear he is all in all with Sir Astley Cooper, and that he and Bransby have made friends. Mr. Liston is also very intimate with him.

My money is nearly out, having paid for lectures and hospital; please send me a remittance as soon as possible. I am afraid I must quit my present lodgings, as the landlady imposes very much upon me; half a pound of tea only lasted me a week, and you know I was never partial to it except at breakfast; and, besides, there are a great many extra charges which I never calculated upon. Would you approve of my joining a young Scotch student, from Edinburgh? we could, as it is called here, "chum" together; he is a very clever young fellow, and attends the King's College.

Tell aunt Sarah it is impossible to procure the *everlasting* darning needles; when I asked the shopkeepers for them here, they all appeared quite ignorant of such things; and one of them had the impudence to ask me what she wanted

two of them for, when one would last for ever.

I must now conclude, dearest father; give my affectionate love to all at home, and let me hear from you soon, and a double letter. I'll pay every attention to my studies, and do every thing you desire.

Ever dear father,
Your affectionate son,

THOMAS.

P. S. I wanted to get in a hurry to Guy's Hospital last week, and got into a *Bus*, but forgot to ask which road it took, and in forty minutes I found myself at Greenwich, which was very provoking, as I lost a capital operation.

HOMŒOPATHY.

TO THE EDITOR OF THE LONDON MEDICAL AND SURGICAL JOURNAL.

Sir,—As I, the individual referred to in the last number of your Journal, under the feigned name of "Fritzback," am now practising homœopathic medicine in London, I feel myself called upon to trouble you with a few remarks in reply to the Review.

I am constrained to admit that the *old women* constituting the French Academy of Medicine, have from the basest of all, namely, pecuniary motives, denounced this true and only rational system of treatment. I will farther concede that the remedies prescribed for the *gastronomic valet* and the *concupiscent chambermaid* were in strict accordance with the wholesome doctrines expounded by our illustrious founder, Hahnemann, in his "Organon;" a work, which like its prototype, the *Novum Organon* of Lord Bacon, shall survive when the ponderous volumes by which it has been overlaid, have sunk by their own weight into the dead sea of oblivion.

But, sir, when alluding to the fundamental experiment of the Doctor, the authors seem unaware of the grand principle of inoculating the *materies morbi*. To this point I solicit your attention, and hope to have the honour of submitting to you several authentic cures I have thereby wrought; I shall only instance one at present. The son of an eminent butcher at Whitechapel, laboured for more than twenty years under epilepsy; the paroxysms observing lunar periods. He had consulted the most skilful members of the faculty in London, but without deriving more than temporary benefit.

Having been requested by his disconsolate parents to see the youth, I did so; and have to inform you that, after a few doses of the saliva of a sheep affected with *stagger*, he has been permanently cured.

I am, sir,
Your obedient servant,
HOMŌPATHICUS (verus).
Great Russell-st., London,
April 24, 1837.

MISCELLANEOUS
MEDICAL BOTANY.

COMMUNICATED WITH THE VIEW OF
CALLING THE ATTENTION OF NATU-
RALISTS TO THE MEDICINAL PROPER-
TIES OF PLANTS.

By Dr. CASTLE.

XVI.
FEBRIFUGE ESENBECKIA.

This tree, the *Esenbeckia febrifuga* of St. Hilaire (*Evodia febrifuga* St. Hil. fl. bras. 1. p. 79.) belongs to *Pentandria Monogynia* of Linneus, and to De Candolle's natural order *Rubaceæ*. In height it is about forty feet, common in the province of Minas Geraes in Brazil, where it is vernacularly called *Laranja do Mato* and *Tres Folhas vermelhas*. The leaves are alternate, trifoliate; the leaflets lanceolate elliptic, entire, rather acuminate, and full of pellucid dots. The flowers, which are full of glandular dots, are disposed in terminal, pubescent panicles; calyx five-parted, permanent; petals five, spreading, inserted into the disk; stamens five, inserted with the petals, shorter and alternating with them; filaments oval-shaped, smooth; anthers heart-shaped; ovary sessile, simple, warted, five-lobed, five-celled; styles five, connected together, rising from between the lobes of the ovary, and terminating in a somewhat headed stigma. The bark of the tree is tonic and febrifuge, and is used in Brazil as a substitute for Peruvian bark, to which, it is said to be by no means inferior. BIB. REF.—*St. Hil. pl. usuel. bras. t. 4.*

XVII.
GUIANA SIMABA.

The *Simaba Guianensis* of Aublet (*Zwingeria amara*, Willd.) is an ornamental shrub frequent in the woods of Guiana. It belongs to *Decandria Monogynia* of Linneus, and to the natural order *Simarubæ* of De Candolle. In the stove-house of this country it attains the

height of about eight feet. The leaves are alternate and impari-pinnate, with one or two pairs of oval-oblong leaflets, taper-pointed at both ends, and emarginate at the apex. The flowers are white, usually four-cleft, and disposed in axillary racemes; calyx small, four or five-parted, much shorter than the spreading petals; stamens ten; ovaries generally equal in number to the petals; styles distant at the base, but connected at the top. The fruit is drupaceous. In its sensible medical properties the *Simaba* bears considerable affinity to the *Quassia* and *Simaruba* trees. The bark, leaves, and fruit are bitter, and may be applied to the same purposes as the products of the trees alluded to. It was introduced in 1826; but is not much cultivated. BIB. REF.—*Aubl. Guian. 1. p. 400. t. 153.*

XVIII.
ETHIOPIAN OR NEGRO PEPPER.

This shrub, the *Unona Æthiopica* of Dunal, is a native of Ethiopia and Sierra Leone, belonging to *Polyandria, Polygynia* of Linneus, and to the natural order *Anonaceæ* of De Candolle. The stem varies in its height. The leaves are quite entire, ovate-lanceolate, acute, smooth, with the under surface glaucous. The flowers are situated on peduncles; the calyx consists of three or four sepals; petals six, disposed in a ternary order, with the three inner ones smallest; stamens indefinite; carpels numerous, baccate, terrete, and nearly sessile, many-seeded; and the seeds themselves disposed in a single row. The capsules or seeds are very aromatic and pungent, and were formerly in request under the commercial synonymes of *Negro pepper*, *Monkey pepper*, *Ethiopian pepper*, *Grains de Zelim*, *Guinea pepper*, and *Piper Æthiopicum*; latterly they have not been much used, except to impart their flavour to different liquors. The shrub was introduced into our stove-houses in 1822, but it does not appear to have matured either the fruit or the flowers. BIB. REF.—*Dun. mon. anon. p. 113.*

FRENCH PATENT FOR COPIVI.—M. Mothes, a French Pharmacist, is about to obtain a patent for the gelatinous capsules of Copivi. The invention consists in forming a muco-gelatinous envelope round a few drops of the balsam, whereby its nauseous taste is covered.—*Bull. de l'Institut, Mars 31.*

REVIEWS.

An Analysis of the British Ferns and their allies, with copper-plate engravings of every species and variety. By George W. Francis, Esq., Lecturer on Botany at the North London School of Medicine.

We need only quote the preface of this production to show the high claims of the author as a botanist; and we can assure our readers that the work is ably executed, and is a valuable accession to the botanist's library.

"This motto was my governing principle in writing the following work on the British Ferns and their allies, and in adopting it I hope that I shall neither be accused of arrogance, neglect of the opinion of others, nor yet of unnecessarily varying the details of science. Should the reader ask why I write at all; I answer, because the only book ever published upon this subject (Bolton's *Filices Britannicæ*) has long been out of print, and so much difference of opinion exists as to the identity of some species, and the arrangement of others, that I thought a plain and practical synopsis like the present would be useful to the tyro at least, if not to the practical Botanist.

"The materials from which it has been compiled are these: I inspected all the Herbaria to which I had access, gathered wild and cultivated fronds wherever I could procure them, and wrote to most of our first-rate Botanists for specimens, remarks, and habitats: all these being collected, arranged, and studied, they were described and engraved without reference to any series of plates or descriptions whatever. I then collated these with the works of Linnæus, Willdenow, Sprengel, Swartz, Pursh, Withering, Smith, Hooker, Lightfoot, Hudson, &c. &c., and wherever there was a difference between myself and others, I searched again for the truth; and if still in doubt, have been careful to record the disparity.

"The long introductory matter explains all that is known of the internal structure not only of the indigenous species, but of foreign also, and as it tends to induce in the mind a philosophical knowledge of the plants afterwards detailed, I flatter myself that the part devoted to this will not be the least valuable to the student of nature.

"The manner in which the object has been accomplished, it is necessary to explain more in detail; and first, as to the illustrative plates. They are small, for the sake of economy, and are intended

chiefly to indicate the habit of the plants, while the magnified parts show their detail. They might have been finer as works of art; but, had they been executed by an engraver, minute as they are, they would perhaps have been less botanically accurate, as the smallest variation in many of them would materially have altered their character; and therefore, although a first and an untutored attempt at etching, I have preferred executing them myself, especially as by so doing I should save a large expense, perhaps not to be refunded by the sale of the work. The plate of Genera is a new feature in illustration, and it is hoped a useful one.

"In the record and detail of species, the following order is observed:—First, the Latin and English name, and reference to figure; secondly, those essential characters which alone are necessary for discriminating the species, and which alone the true botanist will find it convenient to consult. The Synonymes and references to figures in other works which follow, give a history of the plant, and enable the student to refer elsewhere if in doubt. The description may be considered collateral evidence, while the remaining parts will show him the varieties to which his plant is subject, the cause of them, its particular and general distribution, and the peculiarities attached to it.

"In the part of the work which treats of the Genera, the reader will find, first, the derivation of the Genus, and a concise account of its general characteristics, and under it the arrangement of the species, according to their obvious distinctions.

"In the Essential Characters of the different species, as few words as possible have been used, and those few pure and scientific. In The Synonymes, which go back to the time of Linnæus (or in some few instances a little before), the names of authors only are given, unless they have called a plant by different names in different of their works, when the works themselves are also specified. In the descriptive part, and discriminating remarks which follow it, pure scientific detail has not been so much aimed at as obvious differences and popular observations. The habitats have been collected from every authentic source which was attainable by me; a vast number will be found which have not been recorded before, and those few which are contained in previous publications, have most of them been lately authenticated.

"Information of this varied and local kind cannot, of course, be expected from any one's unassisted labours; I have therefore had recourse in the latter part to the assistance of friends, and I cannot speak too highly of the kindness and warmth with which my advances have been received, and without which indeed very much interesting matter must of necessity have been omitted. I hope that I have acknowledged in every instance the remarks thus received. My obligations are particularly due to H. C. Watson, Esq., who very kindly left out of his new *Botanist's Guide* any account of the Ferns, on the purpose that I might benefit by his checked lists; also for the valuable remarks of Mr. W. Wilson, Mr. W. Leighton, Dr. Murray, Mr. W. Pamplin, Mr. Beevis, Dr. Castles, and Rev. W. Bree.

"And now, kind reader, I leave the work in your hands, concluding with the words of Linnæus to Haller:—'If you have remarked errors in me, your superior wisdom must pardon them. Who errs not while preambulating the domains of nature? Who can observe every thing with accuracy? Correct me as a friend, and I as a friend will requite the kindness.'"

Memoire sur l'Emploi des Preparations d'Argent dans le Traitement des Maladies Veneriennes, 1836, par M. SERRE, Professeur de Clinique Chirurgicale a la Faculte de Montpellier, &c. &c.

The author has tried, it seems, the simple chloride of silver, the ammonio-chloride, the oxide of silver, the silver in a state of minute division, the cyanide and iodide of silver. He finds the simple chloride and the ammoniaco-chloride, however, to be the two most certain and efficacious preparations. He administers them in pills according to the following formula:

R. Pulv. iridis Florent gr. ij.
Argenti Ammon. Chlor. gr. j.
Conserv. Tiliz. q. s.

M. et divide in pil. xii. vel. xiv.

He begins with the tenth or eighth of a grain of simple chloride, without the least inconvenience; but has never ordered at the commencement more than the twelfth of a grain of the ammonio-chloride. The doses are progressively augmented during the treatment. M. Serre thinks it better to apply the medicine by friction on the tongue than in pills.

He has related twenty-two cases of *chancres, vegetations, rhagades, pustules*, cured by this method of treatment. It never induces salivation, nor exercises any bad effect on the digestive tube or pulmonary organs, like mercury. It is besides less expensive than the preparations of gold sometimes prescribed in venereal complaints.

M. Serre deserves credit for his researches; the results of which we hasten to make known to the Medical Profession of this country.

LITERARY INTELLIGENCE.

Experiments on the Physiology of Comparative and Human Generation, with an account of Oology and Embryology from the lowest to the highest classes of Mammiferous Animals, illustrated by numerous Plates drawn from original dissections, by John Miller, Mechanic and self-taught Student of Comparative and Human Anatomy; with the Life of the Author, by himself. To be published in 8vo. in October 1837, by subscription, to be paid for on delivery of the work.

CHARING CROSS AND WESTMINSTER HOSPITALS.

"It's an ill wind that blows nobody any good."

The funds of the Westminster Hospital have been much benefited by the late disturbance at the Charing Cross Hospital, many of the subscribers having transferred their annual donations to the former *real* charity; and it is with pleasure we are enabled to state that an extra spacious ward has been lately opened, and that in the course of the ensuing week a second ward will be ready for the reception of patients. The number of patients now in the Hospital, amounts to upwards of 120.

THE UNIVERSITY COLLEGE.

GENERAL AND CLINICAL SURGERY.

Sir,—In the hope that your numerous readers will be gratified to learn, I beg to inform you that the whole arrangements for the completion of the Surgical Course at University College are at length arranged. The operations will be performed in a complete and somewhat novel method by Professor Richard Quain, whilst the principles of Surgical Science, and the propriety and necessity of performing

each operation will continue to be fully explained and established by Professor Cooper. The pupil will therefore, without any additional fee, have a double advantage. The operations will commence at the toe, and be carried on progressively upwards to the occipito atlantal articulation, according to a *scale of time*, as laid down by Mr. Liston, an outline of which I have only yet seen in the hands of a pupil: the following is a copy.

Great toe, 1 minute—Little ditto, 40 seconds—Intermediate ditto, 45 to 50 seconds—Metatarsus, $4\frac{1}{2}$ minutes (Chopart); 1 minute, 42 seconds (Liston)—Amputation below knee, (Flaps) $2\frac{1}{2}$ minutes; (Circular) 5 minutes—Hip Joint, undecided—Penis, 1 second—Lower Jaw, 23 minutes—Upper ditto, 26 minutes—Both Jaws, 30 minutes.

The operations of the upper extremity run in the same gradation, according to size, as in the inferior limbs.

Passing the catheter with both hands, 3 minutes—With one hand, 65 seconds—Lithotomy not to exceed one minute—Lithotripsy, time unlimited.

Your constant reader,

A PUPIL.

TO CORRESPONDENTS.

We have to apologize to several correspondents for not noticing their communications last week for want of room.

A North London Student.—The observations upon the itch insect are quite fabulous, and are too ridiculous to insert in this journal.

W. W.—The letter thus signed is left for the writer, agreeable to his wish, at our office. If he will consult our 25th number for last year, he will find all his opinions anticipated.

Z. will find one grain of aloes act on the bowels in the case alluded to as freely as a larger doze.

A Defrauded Student.—The nearest Police Magistrate will give proper advice under the circumstances. A letter to the Council of the Royal College of Surgeons, and another to the Court of Examiners of the Society of Apothecaries, stating the circumstances, would have a wonderful effect.

Mica Panis.—The Whiting loaves ought to be analysed.

A Disappointed King's College Student.—The attack, though justifiable, is much too personal. A letter to the College of Surgeons, and another to the Hall, would act as powerful stimulants.

A Charing Cross Pupil.—The communication, though we believe it perfectly true, cannot be inserted. It contains at least six libels—"for the greater truth, the greater the libel." Shade of Bentham!

A King's College Medical Student.—This letter is too personal. "The contemptible puppy" alluded too will meet with his deserts at Charing Cross.

Medicus.—It is not prudent in criminal cases for the medical witness to publish his opinions before the trial in a court of law.

Justus.—The suggestions will be duly attended to.

A Plucked Author.—Our correspondent was grossly imposed on by his publisher. His only recourse is an appeal to a court of law.

T.—The parties concerned withdrew their connexion immediately after the exposition.

Elector.—The communication relating to *Wesminster* politics is not adapted for our pages; we wish to confine this Journal to the exposure of medical abuses, unconnected with electioneering intrigues.

Calculator.—The Lectures which have been delivered both by Sir Benjamin Brodie and Mr. Guthrie, these individuals were compelled not to charge any fee for, in order to prevent their being charged with *favoritism* when employed as examiners at Lincoln's Inn Fields. Under other circumstances, there is no reason to suppose that these highly exemplary individuals would not have received an honorarium.

North Staffordshire Infirmary.—Mr. Lawrence, consistent with his well known liberal principles, and in accordance with the opinions he has so emphatically and so long declared publicly, has just brought forward a motion before the Council of Lincoln's Inn Fields, seconded by Mr. Howship, that in imitation of Richter, of Gottingen, and Scarpa, of Pavia, all hospitals for clinical instruction, containing at least FIFTEEN beds should be considered fully adequate for instruction of students, and duly recognised accordingly.

Cantab.—There is no difference in the comparative value of an Oxford and a German degree. Dr. — and the — can give every information.

A Sufferer.—The veratria will not afford the slightest relief. A combination of hyoscyamus and opium is sometimes useful in such cases.

guages—Astonishing Rapidity of Thought in Sleep, and Insanity—Difference between Insanity and Delirium—General Observations—Plan of the Courses—Extent of the Subject—Physiology, Etiology, Semiology, and Therapeutics—Theory of Medicine—Its Relations with the other Medical Sciences—Necessity of a specific Course of Lectures on Physiology.

A high instep is a mark of a well-formed foot. The muscles which rotate the thigh outward, being stronger than those which rotate it inward, the toe is naturally turned a little outward; and this seems necessary in order to bring the ball of the great toe to the ground in such a position as to make it a fulcrum for poising the body. Women walk either less firmly than men, or with a rolling motion. In walking, especially up a hill, the extensors of the thigh and foot are most fatigued; for they have to pull up the body, first on the knee, and then on the foot. In coming down a hill, the muscles of the back are most fatigued; for they have to keep up the body, in opposition to its tendency to fall on the nose. We use the flexors most in running, and the extensors in walking; and if fatigued by running, therefore, we straighten the limbs; but if tired by walking, we bend them. A sharp walk is less fatiguing than a slow one; because it gives the body a greater projectile force, and the *vis inertiae* becomes a substitute for muscular exertion. Hence a drunken man runs, when he cannot walk; for in walking, each step requires a fresh volition; while in running, the foot is instinctively thrown forward, to prevent the body from falling.

Leaping is performed by a sudden extension of the lower limbs, after flexion; thus imparting to the body the force of a projectile; and swimming is a leap in the water. A man thrown overboard in deep water, does not sink to the bottom; for,

K

at a certain depth, it is as impossible for him to sink as it would be in mercury. I have seen a fat man (who could not swim by art) fall into the Thames several times, but it was impossible for him to sink. The great quantity of fat in the head of whales tends to keep it above water. Fish in water, under an exhausted receiver, remain at the surface in spite of themselves. Magendie says, that swimming is performed by renewing the column of water under the body, before the first column has time to be displaced. He considers that flying is performed in the same way, by renewing the column of air. Some squirrels can fly by means of membranes attached to the lower extremities as well as the upper. Some fish also have the power of flying, by means of membranous expansions.

The way in which lizards crawl up a perpendicular surface is by forming a vacuum with the foot, in the same way as flies. The walrus crawls up rocks in the same way, producing a vacuum by drawing the toes together, and then expanding the foot.

If a man dances, sings, and plays a musical instrument at the same time, it is said that he calls into exercise three hundred muscles at once. In striking a blow, we first pull back and bend the arm, and then project and straighten it. There are no really voluntary muscles in the body; for we cannot will to move any particular muscles. We can only will certain motions; and therefore motion is voluntary. Volition is not the immediate stimulus to motion; but calls into play an irritation of the anterior spinal column, where grey matter is found. Other stimuli acting on these columns may likewise produce motion. Motion may sometimes result, perhaps, from increased relaxation. Thus a tremor is from diminished action, and approximates to palsy; while a convulsion is from increased action, and approximates to spasm. When the jaw chatters, it is from tremor, produced by the relaxation of the masseter, temporal, and other muscles.

The muscles are always contracted in some degree, as is proved by the mouth being drawn to the healthy side in hemiplegia; and by the limbs being bent during sleep, from the flexors being stronger than the extensors. When the muscles contract, they gain in thickness what they lose in length; so that probably their density remains the same. Various experiments have been made to determine this point. Sir Gilbert Blane

put a living eel into a flask, into the neck of which he then fixed a capillary tube, and filled the whole with water up to a certain height of the latter. During the contortions of the eel, when the muscles must have been violently contracted, the height of the water in the capillary tube was not affected. In this case, however, when one set of muscles contracted, another set was relaxed: so that the effects of each were mutually counterbalanced. Abernethy put his arm into water, and then contracted the muscles; but this would diminish the supply of blood to the limb, and thus interfere with the accuracy of the experiment. Magendie says that the point is not settled; but that the difference between the size of muscles when contracted and when relaxed is so trifling as not to be worth regarding.

There is a loss of power in the contraction of the muscles, from the following circumstances:—1. From their acting on the principle of the worst form of a lever of the third kind. 2. From the oblique direction in which the fibres of the muscle are inserted into the tendon. 3. From the obliquity of the whole muscle to the bone. 4. From friction. 5. From the resistance of antagonist muscles. 6. From the muscles acting with the same power on fixed and on moveable points, which occasion a loss of half the power. If the muscles of the body were so placed as to have their full power, a man might move Arthur's Seat. The advantages which counterbalance this loss of power in the muscles, are,—1. Symmetry. 2. Celerity. 3. Accuracy. The muscles of speech afford the best example of symmetry; and those of the voice of celerity. Weights hung to muscles removed from the body do not indicate their strength, but their cohesion. The former depends on nervous energy, and therefore cannot be estimated in this way. It must be in proportion to their length, breadth, and extent of motion.

Gordon and Edwards say that muscles do not assume a zigzag form in contracting. Prevost and Dumas are of opinion that the fibres of the nerves enter the muscles transversely to the fibres of the latter; and that the fibres of the nerves are approximated by the nervous power, which they think is galvanism, and that in this manner the muscles are shortened. Brodie found that cutting the nerve of a part did not destroy its power of muscular contraction, upon the application of the galvanic stimulus, but

that cutting the artery did destroy its power of contracting. He concludes, therefore, that the contraction of a muscle depends on the influx of blood into it. But it is only while a part is furnished with blood, that its irritability continues, and if, while in that state, a stimulus be applied, contraction ensues.

Snoring is occasioned by a tremour of the *velum pendulum palati*. It occurs after fatigue, and is an approximation to paralysis. Gaping is a convulsive sigh. The lower jaw is depressed from sympathy between the *portio dura* and the phrenic nerve. Hence it occurs in diseases of the diaphragm. The foregoing take place during the inspiration; the following during expiration. Hiccough is a spasmodic sigh. Hooping depends on the diaphragm also, but in connection with a contracted glottis. Coughing and blowing the nose are of the same nature. There is first a resistance to the exit of the air, and then a forcible expiration. A person cannot cough after tracheotomy, because the latter prevents this, previous resistance being made. The diaphragm is passive in expiration. A groan is an inverted hoop, and frequently does not indicate pain, but a convulsive action of the muscles of the larynx. A scream is an acute groan, the arytenoid muscles closing the rima glottidis more than in a groan. Hydrocephalus causes screaming from the convulsions spreading to the muscles of the larynx, and not from pain. The person who utters the scream may even be completely unconscious, as in hysteria, where the scream is not caused by the passions as usual, but by other causes affecting the nervous system. The constriction of the vocal cords by the thyro-arytenoid muscles, instead of their approximation, makes the difference between whispering and speaking.

The larynx has been compared by different authors to various musical instruments. 1. By Galen to a flute. 2. By Ferris to a violin. 3. By Richerand to a mixture of both. 4. By Magendie to a clarinet. 5. By Dodat to a horn. 6. By Blumenbach to an Eolian harp. 7. By Krantsenstein to a drum. It seems to combine the advantages of all, being both a wind and a stringed instrument, and therefore cannot be imitated. Sobbing, laughing, and crying are convulsive actions of the abdominal muscles, and those of the larynx.

Ventriloquism is said by Dr. Alison and others to be speaking during inspiration. But if you watch closely, you will

see that the lips do not move, and that the chest gets smaller, which proves that expiration is taking place. The explanation appears to me to be this: ventriloquists do with their tongue what others do with their lips; and in them the *portio dura* probably extends farther back than in others. Ventriloquism was once absurdly thought to be caused by the concussion of the omentum and the abdominal muscles: hence its name.

In mastication, the jaw is raised by the masseter and temporal muscles, and is depressed by the muscles which extend between it and the *os hyoides*, for the muscles which raise the *os hyoides* depress the jaw. When the larynx is raised, the vocal tube is shortened, and the voice rendered more acute. The jaw is protruded by the external pterigoid muscle, and rotated by the internal pterigoid.

V. Motions subservient to generation.—The penis is erected by retention of blood, not by increased determination. De Graff said the blood was retained by the penis being pressed against the pubes; but erection rather depresses the penis, and the erector penis would rather impede the flow of arterial blood into the organ, by embracing the *crura penis*. Erection, like blushing, seems to be produced by relaxation and not by compression. The vessels are first constricted by a stimulus and then relaxed from fatigue.

Parturition requires the assistance of the voluntary muscles; for a prolapsed uterus will not bring forth. However, the assistance of the voluntary muscles is not always necessary, for parturition has sometimes occurred after the death of the parent, by means of the muscles of organic life. Labour has five stages. 1. The opening of the *os uteri*. 2. The passage of the head through the vagina. 3. The birth of the head. 4. The birth of the body. 5. The birth of the placenta. The child has its face first to the sacro-iliac synchondrosis, then to the hollow of the sacrum, and when born, it turns to one of the thighs. The placenta is separated by the muscular fibres which surround the mouths of the fallopian tubes. In order to separate the retained placenta, Magendie recommends that cold water, mixed with vinegar, should be injected through the vein of the umbilical cord. The shriveling of this cord which takes place after birth, is a vital process, analogous to the fall of the leaf, or to dry gangrene. A dead child does not cast its cord, which becomes putrid.

SLEEP.

Sleep is not a function, but a diminution of the three functions of which we have last treated,—sensation, thought, and voluntary motion. In incubus, in which sensation is alive, but voluntary motion perverted, the anterior columns of the spinal cord are probably asleep, and the posterior columns awake. In somnambulism, in which voluntary motion is alive, but sensation is perverted, the anterior columns probably are awake, and the posterior asleep. Both incubus and somnambulism are kinds of half sleep.

Cullen said that sleep was occasioned by diminished mobility of the nervous power; others are of opinion that it is caused by pressure on the brain; but we know not how this can come on periodically. Blumenbach says it is from a deficiency of blood in the brain. The grey matter is subservient to sensation, thought and voluntary motion; and if there be too little blood in the brain, too little grey matter will be deposited, and there will be a less display of these animal functions. It is true that in apoplexy, which resembles sleep, there is too much blood; but probably, in that case, it is in the white matter, while there is too little in the grey, for as the brain is incompressible, if there be a redundancy of blood in one part, there will be a deficiency in another. Pressure on the brain, from fracture of the skull, with depression, acts in the same way, by squeezing out the blood. On the same principles, syncope and tying the carotid artery produce sleep. In phrenitis, where there is too much blood in the grey matter, sensation, thought, and voluntary motion are much increased. It is said the thoughts are more energetic when the body is in the recumbent posture, and more vivid on awakening in the morning. Erasmus said that was the best time for learning a language, and I have found it the best time for mastering difficulties.

In sleep thoughts succeed each other much more rapidly than when we are awake. To so great an extent is this the case, that Darwin says the events of two hundred years may be comprised in the dream of half a minute. The same takes place in insanity. In both of these cases there is no judgment to arrest the thoughts. In insanity the patient understands a question put to him, but the thought which it awakens serves as the first link of a chain, and he travels over half the globe before he can reply. Insanity differs from delirium, for in the

latter the patient does not understand the question. If you awaken a person, that very act may give rise to a very long dream in an interval of time quite inappreciable.

Dr. Fletcher's Course of Lectures on the Institutions of Medicine (as may be seen by referring to the Syllabus, published in our Sixth Volume, No. 146, page 487; and No. 147, page 519), consisted of four divisions: 1. Physiology. 2. Etiology. 3. Semiology. 4. Therapeutics. We have now gone through the first of these divisions; and before entering on the others we intend to wind up the physiological part of the course with some general observations by Dr. Fletcher, delivered as an introduction to a previous course.

GENERAL OBSERVATIONS.

It is my design to deliver, in this Course of Lectures, the best description in my power; first, of the several processes going on in the living human body during health; secondly, of the influence upon it of those agents by which diseases are occasioned; thirdly, of the changes observable, as well in the aspect of the body, as in the processes going on within it during disease; and, lastly, of the influence upon it of those agents by which health is restored. A very great part of such explanations being necessarily theoretical, they constitute (collectively taken) the theory or institutions of medicine, or full physiology; the consideration of the first part forming the proper business of elementary physiology, or physiology properly so called; that of the second, of etiology; that of the third, of semiology; and that of the fourth, of therapeutics.

It is obvious that the theory of medicine is connected, more or less intimately, with almost every other branch of medical science; and is taught, more or less fully, by the several professors of each of those branches. The lecturer on anatomy, for example, is almost compelled to intersperse with his descriptions of the various parts of the body, some disquisitions respecting their functions and diseases; the lecturers on the practice of physic and surgery, can hardly enumerate the causes of diseases, their symptoms and treatment, without entering occasionally into some explanations of the nature and operation of the first (the causes of disease), the immediate cause of the second (the symptoms), and the mode of action of the last (the treat-

ment); and the lecturer on the *materia medica* is still more frequently induced to interweave with descriptions of the properties of medicines, some rationale of their beneficial effects. Still, to each of the lecturers just mentioned, the discussion of any one of the topics alluded to, is more or less a work of supererogation. They are indeed so far connected with their immediate business, as to be with difficulty altogether avoided; but at the same time so far estranged from it, as to be omitted without any imputation of neglect. Hence they are commonly touched upon by each, only by fits and starts, without any attempt at a regular system; and the student is thus led, by different professors, perhaps a dozen times through some paths of the extensive district before him; while into others equally interesting, and abounding with equally useful productions, he never enters at all, and is in all likelihood unconscious of their existence. But instructed in this imperfect and desultory way—even admitting (what is very improbable) that the teachers of so many different sciences, all inculcated the same views of matters out of the immediate province of any one of them—it is evidently impossible that the student can attain a comprehensive knowledge of the subjects in question; and it is, at the same time, very improbable that he will attain a true knowledge of them, even as far as they go. For the most part they are brought forward by these volunteer teachers (as they may be termed), with that air of indifference, and, perhaps, of half real, half affected contempt, which men generally display when alluding to subjects not exactly in their own line, and are indeed seldom introduced at all, except when a particularly happy idea has been accidentally stumbled upon; and as the lecturer feels himself under no obligation to prosecute this idea any further than he finds convenient, he is at once cut off from the chief and almost only criterion of its justice. Any person at all versed in the theory of medicine will agree with me when I assert, that it is easy for a man of ingenuity to make any one of twenty different explanations of the same fact, appear equally satisfactory to the uninitiated; and it is only when collated with others, that the hollowness of perhaps the most feasible of them becomes obvious. "The application of particulars to a whole," says Cullen, "will often discover their fallacy;" but the off-and-on teachers of the theory of medicine never

apply their speculations to the whole, but to parts only; and the consequence is, that their theories are not only imperfect as a system, but frequently false in detail.

It was to remedy these imperfections in the system of medical education, that courses of lectures professedly on the theory or institutions of medicine were first established; and attendance on such a course was subsequently made an essential qualification for a medical or surgical diploma. In such a course it is understood that the lecturer, while he is obliged to presume that his hearers are acquainted with at least all the broader facts of anatomy, of the practice of physic and surgery, and of the *materia medica*, and subservient sciences (although he may find himself obliged occasionally to invade some of these departments in illustration of his own), will carry them systematically and in detail, through every important principle of physiology, pathology, and therapeutics; and in such a manner as that one and the same spirit may pervade all his explanations, and that each may be tried, as it is successively offered, by the ordeal of all that have preceded. It is in this way alone, that a comprehensive and consistent system of the theory of medicine, or full physiology, can be conveyed; and it is such a system alone that can be generally useful, or is at all entitled to rank among the medical sciences.

It is not, however, quite superfluous to inquire whether theory, in whatever way it may be prosecuted or inculcated, is of any real utility in medicine; and whether it be not a flickering and unsteady glimmer, adapted merely to amuse the practical man (if not to mislead him), and to retard him on his way to reputation and fortune (if not to divest him from them altogether), instead of being a real and substantial luminary, calculated to light him on the road to success. It is rather too late in our times to revive the old and tiresome contest, whether the practice of the healing art should be strictly dogmatical, or entirely empirical; a contest which, in the minds of all intelligent persons, was long ago settled by the decision that should be neither the one nor the other; but that theory and experience should be regarded in the light, not of adversaries, but of allies; and should be made to co-operate, instead of being adduced in opposition to each other.

LECTURES ON SURGERY,

BY

JOHN HUNTER, F.R.S.

Animal and Vegetable Matter—Origin and Return to Inanimate Matter—Peculiar Properties—Propagation of Species—Physical and Chemical Properties—Morbid Alterations—Information to be Derived from them.

Animal and vegetable matter has certainly been formed out of the matter of the globe, for we find it returning to it again. Both are subject to the laws already mentioned, which regulate common matter, but they are so different, from their peculiar modification, as to appear at first like originally distinct species of matter; though they will be found, on investigation, to be only a new modification of matter.

This change in the original principles of matter seems to be equally distinct both in animal and vegetable matter, and the first principle of action of those two substances seems to be in great measure the same; but there are marks by which they can be distinguished. The connexion of these two modifications of matter with common matter has never yet been traced, nor has the gradual transition from one to the other been imagined; and if those substances had not reverted into common matter by their decomposition, it never could have been suspected that they were originally composed of the same materials. For these reasons they have been ranked by themselves.

Animal and vegetable substances differ from common matter in possessing an additional power, totally different from any other known property of matter, from which various new properties arise.

Animals and vegetables have a power of action within themselves, are capable of increasing their own magnitude, and possess the power, as it were, of working themselves into form and a higher state of existence. This power of action and capability of increase require a supply of materials, as well for the increase as for the waste arising from action. This supply appears not to be wholly the same in both, though perhaps it may be. The idea of a supply always supposes a resource distinct from the thing supplied, and no waste parts can ever perfectly revert into the thing itself without first going through all the changes which first brought it into its natural state.

This supply is furnished by the materials of the globe. Vegetables alone appear to have a power of immediately converting common matter into their own kind. Animals probably have not that power, therefore are removed further from common matter; so that a vegetable seems an intermediate step between common matter and animal matter. But observation will show that vegetables can readily convert both animal and vegetable matter into their own substance, as in the case of dung, which increases the natural growth of plants.

Both have a power of propagating their kinds by a production out of themselves, by which means the stock is replenished.

Both are capable of being in two states; one of these is the living state, which we have been considering, the other is the dead state.

Hence both animals and vegetables are capable of being considered in three ways. 1st, In their power of continuance and production, when possessed of their natural powers of action or life. 2nd, In their chemical nature as matter, which can only be considered when they are dead. 3rd, In their decay, or spontaneous reduction to common matter, when life is gone. In all these operations they are totally different from common matter. The first distinction, or life, in which consists the power of self-preservation, is the antidote to the two last, since before either of these can take place the whole part must be deprived of the living principle. When in the first state, their actions are either natural, the whole being in harmony, and every part acting in concert with the rest, which is called health; or they are unnatural, which constitutes disease, the tendency of which is to destroy the whole.

When chemically considered, both animal and vegetable matter are found to be acted on by different substances, or are capable of solution in other bodies, as concentrated acids, alkalies, &c., in which respect they are pretty similar to one another. Both are capable of being acted on by fire; but in this process we find each yielding some substances peculiar to itself; animal matter when distilled yields water, volatile alkali, empyreumatic oil, and calcareous earth;—besides these there is a small proportion of iron, which does not appear, however, to be a constituent part of the whole animal body, being chiefly procurable from the blood; a small proportion of other

substances may also be found in the blood.

During their decay, both animals and vegetables go through a series of regular spontaneous changes, the succeeding one arising entirely out of the first, and the next out of this, until the whole return to common matter from whence they arose, for they must return to the earth from whence they were produced. In this natural process we find animals and vegetables yield many substances not to be found in them before these changes, also not be found in common matter. This process I call fermentation, and it is peculiar, I believe, to vegetable and animal matter.

The processes carried on by chemistry and fermentation, which can only take place when the parts are dead, have been introduced by physiologists into the living economy; and, not satisfied with this, they have brought in mechanics to account for many of the operations of vegetables and animals. But, for the purpose of distinguishing more accurately between mechanical, chemical, and vital operations, and the circumstances under which the two first are applied to the living body, let us consider them a little further.

The actions and productions of actions both in vegetable and animal bodies, have been hitherto considered so much under the prepossessions of chemical and mechanical philosophy, that physiologists have entirely lost sight of life; and perhaps they have been led to this mode of reasoning because these properties are much more familiar, more adapted to our understandings, and more demonstrable than the living properties of organized beings. But unless we consider life as the immediate cause of all actions occurring either in animals or vegetables, we can have no just conception of either vegetable or animal matter. No wonder, then, that the theories of the older physiologists are ill built and ill supported, their principles being false. Many of the effects, both in animals and vegetables, might at first sight appear to be chemical, or the consequence of fermentation. The production of many juices of plants, such as gums, acids, sugar, &c., would seem to be of this kind; but all arise from natural actions of the vegetable, and do not belong to chemistry. No chemist in the world can make out of the earth a piece of sugar, but a vegetable can do it. Digestion, the formation of the blood, and all the secretions of an animal, might at

first appear to be of this sort; but that they really are not chemical products I am clearly convinced. If an ingenious man undertook to account for every change in matter by fermentation, there is no change in nature that might not be brought within his definition. The living principle itself would be shown to arise from fermentation; brain, muscles, bones would grow from fermentation, since they are all formed from the blood, and yet the blood is not found in them.—Of all things on the face of the earth definitions are the most cursed; for if you make a definition you may bring together under it a thousand things that have not the least connection with it.

What I call fermentation, only takes place in animal and vegetable matter when dead. It is that change which takes place in the substances themselves out of their own spontaneity, without any external assistance. Chemistry is a kind of force on things to decompose them. In the process of fermentation, vegetable matter goes through intermediate stages, in which it is neither vegetable nor common matter; the same with animal matter during putrefaction. But in all the productions of a living animal or vegetable, the substances produced are animal or vegetable matter. The only substance produced in an animal which cannot be called animal matter is the earthy matter of bones, and of some diseased parts: it appears also that, in some of the secretions of animals, the products produced have none of the original properties of animal matter, as the sugar of milk, the bitter principle in the bile, these not having been found in any of the natural solids or fluids by any process whatever. But this does not come up to my notion of fermentation, for no process of fermentation of animal or vegetable matter ever produced either one or the other; and even in vegetables, where sugar seems to constitute part of the plant, it is formed by the action of the vegetable. If ever any matter is formed in one of the juices secreted in some part of a vegetable or animal body similar to what arises from fermentation, we may depend on it it arose from that process, but we may also depend on it that there is a defect of the living principle in those cases.

The conversion of water into vegetables, which is vegetation, or of vegetable and animal matter into animals, which is animalization, is not a change taking place according to the nature of the substance, but is effected by the actions of the

vegetable or animal. The different juices formed from the blood, called secretions, differ not from the nature of the blood as animal matter, all giving nearly the same substances when analysed, or subjected to fermentation. Nor can the substances formed in a vegetable be formed, by any process that we know of, from water. We might suppose that fermentation would produce an animal from a vegetable, because in this change "a decomposition of matter and a new combination" are effected; but fermentation never could bring back dead animal or vegetable matter to living, so that it does not correspond to the above definition which has been given of it. This single circumstance throws more light on the power of the stomach than we are yet aware of, for dead matter subjected to it is not obliged to undergo any change as matter, but goes through that process which produces life.

In treating of an animal body I shall always consider its operations, or the causes of all its effects, as arising from the principle of life, and lay it down as a rule that no chemical or mechanical property can become the first cause of any of the effects in the machine. But as all animals have form and motion, which motion is directed by that form, these motions become mechanical, so that every motion may be truly called mechanical. Mechanics are therefore introduced into the machine for many purposes. The living principle, however, in itself is not in the least mechanical, neither does it arise from, nor is it in the least connected with, any mechanical principle.

Having thus given a general idea of these singular combinations of matter, I shall now confine myself to animal matter. But before I treat of the diseases of the animal body, which is the intention of these lectures, it will be necessary to give such general ideas of the subject, and to lay down such axioms and propositions, as will enable you to follow me through all the necessary descriptions of preternatural actions of the machine. This matter we must consider in two points of view: 1st, in its production; 2ndly, in its continuance. This leads me into a new field, and exhibits properties very different from all the other properties of matter. It will be necessary, I say, to have clear and distinct ideas of the difference between animate and inanimate matter, in order to know when and where the animal principle acts, and when other principles are employed in an

animal body in accomplishing all the different purposes of life. The human body is what I mean chiefly to treat of; but I shall often find it necessary to illustrate some of the propositions which I shall lay down from animals of an inferior order, in which the principles may be more distinct and less blended with others, or where the parts are differently constructed, in order to show from many varieties of structure, and from many different considerations, what are the uses of the same parts in man; or at least to show that they are not for the uses which have been commonly assigned to them; and as man is the most complicated part of the whole animal creation, it will be proper in the first place to point out general principles common to all this species of matter, that I may be better understood when I come to the more complicated machine, namely, the human. Besides having recourse to many of the inferior orders of animals for the elucidation of some of the phenomena of the more complicated orders, we are also obliged to disease for many of our hints on the animal oeconomy, or for explaining the actions of parts, for the wrong action of a part often points out what the natural action was, and gives an idea of life. Disease often corrects our imagination and opinions, and shows us that such and such parts cannot have the uses commonly attributed to them, and therefore brings us a step towards the knowledge of the true use. Monstrosities contribute to rectify our opinions in the same, if not in a more intelligible manner. A monster is either from a deficiency of parts which can be produced from art (and often is from necessity, as in operations,) or else from a modification caused by a wrong arrangement or construction of parts, which will produce an unnatural action, by which means the natural action may be known.

DISEASES OF THE HEART.

(Continued from p. 108, No. 4.)

CHANGES IN THE DIMENSIONS OF THE CAVITIES AND ORIFICES OF THE HEART.

Dilatations of the heart were termed aneurisms by authors until a recent period; the one species was called active, which was dilatation with hypertrophy,

the other species was termed passive; which consisted of dilatation, with thinness of the parietes.

Dilatation of the cavities and orifices of the heart may be general or partial, and accompanied by thickening or thinning of the parietes. Dilatation with thickening constitutes aneurismal or excentric hypertrophy, which was formerly termed active aneurism or hypertrophy. Dilatation with thinning of the parietes was termed passive aneurism. Cases are recorded in which the right cavities of the heart were prodigiously dilated and thinned, and the auricle appeared similar to a transparent membrane. (Fleury, Bouillaud.)

Dilatation may affect one, many, or the whole of the cavities of the heart, and may or may not be accompanied by hypertrophy, or thinning of the extended parietes. In some cases, when complicated with hypertrophy, the heart becomes double or treble its ordinary size, and may become more or less irregular in form and situation.

Partial dilatation of the heart is sometimes preceded by rupture of the internal layers of the parietes of the organ, which is followed by the formation of an aneurismal cyst. The most frequent dilatation is observed in the pulmonary portion of the right ventricle.

Dilatation of the orifices of the heart. M. Bouillaud describes cases in which the auriculo-ventricular orifice was four, and in one case five inches in circumference. It is evident that in such cases the valves cannot perform their functions properly, and there must be more or less derangement of the action of the heart during the passage of the blood through it.

The cavities of the heart, like all hollow organs, dilate when there is any impediment to the course of the blood or other substance, which is to pass through them. Thus in bad stricture of the urethra, the bladder enlarges, in contraction of the pylorus, the stomach enlarges; and in stricture of the intestine, the tube increases in size above the obstruction. In the same manner the valves of the heart are diseased and offer obstruction to the passage of the blood, the cavity above them becomes enlarged as the accumulation of blood distends its parietes. It is also important to state that the auricles more readily dilate than the ventricles, and that the right ventricle more readily than the left. The auricle is distended when the auriculo-ventricular opening is contracted, and the ventricle

when the arterial valves are affected. But it often happens, on account of the difference of resistance in the different cavities of the heart, that the cavity nearest to the obstacle is not always the first which is dilated. Thus when the aortic valves are diseased, the left auricle is often dilated before the left ventricle. It is also to be remembered that the different cavities of the heart which are closely connected with each other, are often dilated by any great obstacle to the course of the blood through them. Besides the mechanical force, the blood possesses an excitant and irritant power, in consequence of which the nutrition of the heart becomes frequently increased, so that the same cause of obstruction to the circulation will not only cause dilatation, but hypertrophy. But if hypertrophy does not ensue, the contractility of the heart will be more easily overcome by the dilating power, and the circulation will be greatly diminished and impeded. Hypertrophy is not a constant complication with dilatation of the heart, and in many cases the dilated parietes are thinned, and to this disease the term passive aneurism was applied by Corvisart.

Causes.—The causes of dilatations, or aneurisms of the heart are all violent exercises and all trades which require powerful muscular exertion. Thus porters, wheel-wrights, paviours, &c., are often affected with this disease. All such causes tend to accumulate the blood in the heart. Powerful mental emotions, such as anger, hatred, jealousy, grief, &c., and the occupations which require the expression of the passions, as those of the tragic actor, the vehement orator, &c. are causes of dilatations of the heart.

Among the causes are deviations of the spine and all vices of confirmation, tight lacing, &c., which diminish the capacity of the chest, and the latter compressing the abdomen and impeding respiration and circulation, induces passive congestions of blood, or determination of blood to the brain, lungs, heart, followed by serous effusion, and often accompanied by a sense of suffocation.

Diagnosis and treatment.—The diagnosis has been given in the accounts of hypertrophy and atrophy of the heart and endocarditis. It is now only necessary to observe that when the valves do not completely close the orifices to which they are attached, there will be a reflux of blood which will cause the bruits, termed *de soufflet*, *de cataire*, and when

the obstruction is in the left auriculo-ventricular opening, it gives rise to pulsation of the veins, and to fluctuation in the jugular veins. (See endocarditis.) While writing this article, I have a most remarkable case of this kind under my care at the Metropolitan Free Hospital, which is now greatly relieved by the use of the hydriodate of potass, in combination with digitalis, colchicum, the sedative solution of opium and hydrocyanic acid.

The treatment is the same as for hypertrophy and atrophy of the heart, as already described.

CONTRACTION OF THE CAVITIES AND ORIFICES OF THE HEART.

These diseases are caused by thickening of the endocardium, (see endocarditis) and especially of the fleshy columns and deep-seated muscular layers, by compression of tumours, effusions, &c. on the heart, and the presence of sanguine concretions, whether recent, chronic, or organized. Contractions of the cavities of the heart impede the circulation and give rise to venous congestions, serous effusions, or dropsies in the different parts of the body. If the contraction occupies the left ventricle, the pulse will be small, as if the aortic orifice was affected. The contractions of the valves and orifices arise from the same cause, which is endocarditis, the treatment of which has been already described. In addition to the usual depletory measures, great advantage will be derived after the acute form of the disease has passed by, from the use of the hydriodate of potass in gradually repeated doses, leaving an interval of ten or twelve days between the period of augmenting the quantity.

I am in the habit of employing the following combination with great benefit in hypertrophy of the heart, induration of its valves, in chronic rheumatism, with enlargement of the joints, in nodes and secondary syphilis.

Rk Potassæ Hydriodatis ʒj. jss. ij.
ijss. iij. ijss. iiij;
Aquæ Menthæ Pip. ʒvij;
Vini Colchici ʒj. jss;
Liquoris Opii Sedativ. ʒj;
Tinct. Digitalis ʒj;
Dosis ʒss. 3 in die.

The digitalis is omitted, except in certain cardiac diseases, and the hydriodate should be gradually increased to the maximum dose, which few can bear,

though M. Magendie has strongly advised it.*

PHYSICAL AND MECHANICAL LESIONS OF THE HEART.

The solutions of continuity of the heart may be spontaneous or traumatic, or caused by cutting instruments.

Ruptures of the heart are caused by ulcerations, or the bursting of aneurismal tumours of this organ, and they appear to affect the left cavities more frequently than the right, in the proportion of six of the left and four of the right, into ten cases. (Bouillaud.) In the last four cases it was the auricle that gave way. In four of the first six cases the rupture occurred in the wall of the left ventricle; in one case it affected the mitral valve, and in another the columns of the ventricle. In none of the ten cases were the interventricular and interauricular walls affected. In some cases there is one, in others there are two, three, or five ruptures. (Ollivier, Rostan, Morgagni, Portal, Bland, &c.)

Causes.—The causes of rupture of the heart are predisposing and exciting. The predisposing are ramollissement, or softening, thinning, abscess, or ulceration. The exciting causes are violent concussions of the body in general, or of the heart; violent and sudden efforts, and in some cases the exertion of walking, riding, laughing, coughing, sneezing, &c.

The mechanism of rupture of the heart is the same as that of the stomach, uterus, liver, certain muscles, &c. Mr. Allan Burns was the first who explained that rupture of the heart might be caused by violent action of the organ, in the same way as that of the womb during very violent expulsive contractions, during difficult parturitions.

Symptoms and diagnosis.—When the ruptures of the heart are extensive, there will be a sudden effusion of blood into the pericardium, and in some cases the patient dies as suddenly as if struck with a thunderbolt. M. Rostan describes a case of rupture, in which a coagulum stopped the opening, prevented copious hæmorrhage and sudden death. When the rupture is situated in the partition of the ventricles and the auricles, there will be a mixture of black and red blood, and

* See my Medico Chirurgical Formulary, 1837; and also my Practical Formulary of European and American Hospitals, second edition, 1836.

according to some authors, cyanosis, or the blue disease, will be produced.

In other cases there may be rupture of the fleshy columns, valvular tendons or valves, and then there will be more or less disorder of the circulation. MM. Bouillaud and Tarral state there may be a simple or a sibilant bruit de soufflet; but the former author has heard it when no such lesion existed.

Ruptures of the parietes of the heart with effusion of blood into the pericardium are necessarily fatal. But this is not the case with those of the interventricular or interauricular partition, of the fleshy columns and of their tendons; but the present state of science does not enable us to form an accurate conclusion as to the symptoms or results of the latter diseases. It is scarcely necessary to observe that there can be no *effectual treatment* for extensive ruptures of the heart, of its fleshy columns or tendons.

WOUNDS OF THE HEART.

Wounds of the heart may be penetrating or not penetrating. They may be complicated with the presence of the foreign substance, which inflicts them as a ball, or piece of cutting instrument. The best account of them is that of Ollivier. (Dict. de Medecine, T. viij, en 25 vols.) This author describes sixty-four cases, in twenty-nine of which the lesion was in the right ventricle, which forms the most uncovered part of the anterior surface of the heart; the left ventricle was injured in twelve cases; the two ventricles nine times; the right auricle three times; the left auricle once; the apex of the heart seven times; but in three cases the seat of the wound was not described. A fractured rib may also wound the heart.

Prognosis.—The majority of wounds of the heart are suddenly fatal, though in some cases death does not take place for a greater or less period of time. In extensive wounds of the heart, the patient dies as suddenly as if struck with lightning; quasi fulmine ictus concidit, says Diemerbroek, in describing the death of a duellist, who was stabbed with a sword through the left ventricle. But wounds of the left ventricle are not always suddenly mortal. Morgagni mentions the case of a man who received a stab of a knife through the anterior part of the left ventricle. There was but a very slight discharge of blood at the moment of the injury. After having walked about sixty steps, the wounded man sat

down, and he died in about half an hour, while vomiting his dinner. A soldier fell on his bayonet, which penetrated between the sixth and seventh rib on the left side. He survived for forty-nine hours, and expired on the night-chair. A young man was stabbed with a knife under the left breast, and was seized with frequent fits of syncope. He did not expire until the tenth day after the wound was inflicted. There was a penetrating wound of the left ventricle.

According to M. Ollivier, wounds of the left ventricle are most suddenly fatal. He proves that wounds of the auricles are not so suddenly fatal as is generally supposed. On comparing the different cases of wounds of the heart, he states that wounds of the right ventricle are of the most common occurrence, but less frequently mortal.

The cause of sudden death in wounds of the heart is the compression of the organ by effused blood into the pericardium. (Morgagni, Ollivier.) This conclusion is doubted by Bouillaud. Bartholin was of opinion that the straightness and obliquity of the wound tended to retard death. M. Ollivier considers that the direction of the wound is the cause of prevention of sudden death; thus a wound of the left ventricle may only separate the superficial layers of the muscles, and transversely divide those of the deeper layer, and *vice versa*. A transverse wound in relation to those layers will suddenly give rise to a fatal hæmorrhage. Here we should consider the influence of the particular form of the cutting instrument, which traverses the thickness of the ventricular parietes. According to M. Samson the want of parallelism of the fleshy planes of the heart is the condition which most particularly favors the formation of a coagulum capable of stopping the wound.

These facts are not only deeply instructive in a pathological, but in a medico-legal point of view. A case is mentioned by Mr. Guthrie, in which a flap of the substance of the heart hung down from the organ, and death did not take place for some time afterwards.

Treatment.—Many cases prove that wounds of the heart are not necessarily fatal. The following plan of treatment is proposed by M. Ollivier. (d'Angers, op. cit.) The first indication to be fulfilled is to enfeeble the circulation by copious and repeated bleedings, and to moderate at the same time the movements of the heart by digitalis, &c. It

is also necessary, according to the advice of M. Samson, to keep the patient in an atmosphere as cold as possible, and to apply ice to the chest. The most perfect repose should be observed, the patient should be kept quiet in bed, and free from all mental emotions. The external wound should be closed in the usual manner, so as to favour the formation of a coagulum, which would stop up the wound. The most rigid antiphlogistic plan should be enforced. The lowest diet, with nauseating doses of tartarized antimony are likewise beneficial in such cases.

CONCRETIONS, OR POLYPI IN THE HEART.

Coagulation of the blood in the heart and in some of the large blood-vessels may occur during life, and give rise to concretions, which were formerly termed polypi. These are now generally divided into two classes, the recent or amorphous, and those of long duration, which are more or less organized. M. Bouillaud has detailed the histories of several cases, and he divides them into three species. 1. The recent or amorphous concretions, developed during the agony of death, or in a very short time after death.* 2. Concretions which have undergone the first degree of organization. 3. Those that are perfectly organized.

M. C. J. Legroux gives a very full account of concretions developed during life in a work expressly on the subject,† which I shall quote freely in this article.

RECENT, OR AMORPHOUS CONCRETIONS, WITHOUT ANY EVIDENT TRACE OF ORGANIZATION.

M. Bouillaud describes two remarkable cases of this disease, which were preceded by a sensation of sudden suffocation, and followed by sudden death. The first was that of a man aged 57 years, who laboured under disease of the heart with paroxysms of orthopneic respiration, and who expired suddenly. During the fits of extreme difficulty of respiration, the pulsations of the heart were strong, irregular, and dull, whilst in the moments of calm, they were very sonorous. Copious blood-letting afforded immediate relief.

* These concretions do not differ from those formed after death, and which are met with in almost all dead bodies.

† *Recherches sur les Concretions Sanguines, dites Polypiformes développées pendant la Vie.* Paris, 1827.

Death, however, finally took place during a paroxysm, and amidst the agonies of suffocation. The cavities of the heart contained enormous clots of black fibrinous blood, and the largest was in the right auricle.

The second case was that of a child treated for acute bronchitis, which became attended with orthopnea, lividity of the lips and cheeks, jactitation, and inexpressible agony. The pulsations of the heart were precipitate, irregular, and slightly sonorous, and there was a dull shock behind the sternum with a feeble pulse. Death took place in a few hours. The left cavities of the heart contained clots of blood; the right cavities were filled with a fibrinous clot of a citrine colour, semi-transparent and interlaced with the fleshy columns of the heart, and valvular tendons, and which extended into the pulmonary artery, and into the superior and inferior cava.

SANGUINE CONCRETIONS WITH RUDDIMENTS OF ORGANIZATION, WITH OR WITHOUT THE PRESENCE OF PUS.

These resemble pseudo-membraneous matter, the result of inflammation. M. Bouillaud relates eleven cases of this description, the results of which were the following: The first case was that of a man aged 67 years, affected with double pneumonia, with extreme orthopnea. The concretions were similar to false fibrinous membranes, commencing organization on the fleshy columns and valvular tendons. The second case was that of a woman aged 86 years, whose right ventricle contained semi-fibrous concretions. Another patient laboured under acute pleuritis, one under acute rheumatism, one under disease of the heart with venereal disease, and others under cerebral disease, typhoid enteritis, and urinary abscess.

FIBRINOUS CONCRETIONS ENTIRELY ORGANIZED.

A girl aged 18 years, affected with a large tumour of the shoulder and in the axilla, was seized with hæmoptysis. The right auricle of the heart was filled to a great extent with a concretion, in the centre of which there were vesicles filled with a semi-concrete matter. This polypiform concretion was traversed by an infinity of vessels, injected with red and black blood. It extended into the superior vena cava, the right subclavian and jugular veins, with the parietes of which it was confounded as if by continuity of

tissue. It was also prolonged into the right ventricle.

Another well marked case, was that of a man aged 36 years, who was supposed to labour under aneurism of the heart. The right cavities of the organ contained clots of blood, and a fibro albuminous organized substance, adherent to the parietes of the cavity by filaments which required to be torn to separate them; and they were prolonged into the vena cava superior, and also into the pulmonary artery, whose orifice they almost completely obstructed.

GENERAL HISTORY OF SANGUINE CONCRETIONS OF THE HEART DEVELOPED DURING LIFE.

Situation and Anatomical Characters of Polypiform Concretions of the Heart.

—Sanguine concretions are most frequently found in the right cavities of the heart, and in the auricles more than in the ventricles. The reason of this fact is, that the course of the blood is more easily arrested in the right than in the left cavities of the heart, and that phlebitis more frequently extends to the right than to the left side of the heart, and perhaps that there is a more marked disposition to coagulation in venous than in arterial blood.

The anatomical characters of concretions vary very much. Thus the recent ones do not differ from a clot of blood in a common vessel after venesection; and the quantity in the cavities of the heart has amounted to twelve ounces, (Bouillaud) but some of which clots were formed after death. The organized concretions present different characters according to the state of their evolution. Thus in the first stage of their evolution they are whitish, analogous to gluten or prepared fibrin, elastic, and slightly adherent to the parietes of the cavities of the heart, to the fleshy columns and valvular tendons round which they are entwined. At this period of rudimentary organization, they may be compared to the buffy coat on the blood drawn during acute inflammation, or to false membranes in the commencement of their organization on serous membranes. In fine, there are intermediate degrees from the gelatiniform to the fibrous state, which appears to be the last term of density of concretions. (Legroux.)

When the concretions are in a more advanced state of organization, they adhere by real cellular tissue to the parts on

which they are formed (Bouillaud); and thus engrafted on living parts they penetrate the vessels, they become hardened, and they truly resemble certain fibrous polypi, fungous vegetations, and tumours. M. Legroux has found concretions so intimately connected with the valves, that it was difficult to determine whether they were formed by the blood in the cavities of the heart, or secreted by the inflamed tissue. In some cases there is a quantity of pus in the centre of the concretions, and these then resemble real unilocular or multilocular cysts. In other examples there are whitish, glutinous, membranous masses, which are the first lineaments of organization. Some ascribe the pus in concretions to inflammation of the concretions themselves;—(Legroux and others)—while Bouillaud is of opinion that it is secreted, and then surrounded by the clot; but this able author does not deny that sanguine concretions may inflame and suppurate. These concretions may undergo various transformations, and they diminish the cavities and orifices of the heart according to their size. It is important to recollect this fact, for it is to it that the principal symptoms of concretions in the heart are to be ascribed.

Causes and Different Modes of Formation of Polypiform Concretions in the Heart.—Sanguine concretions are developed in the heart, arteries, and veins, under the influence of purely physical and mechanical conditions, which oppose the circulation of the blood, and also by causes which act chemically on this fluid flesh. In the first case, concretions are formed by a mechanism similar to that of coagulation of the blood after it has escaped from the vessels; but this process is as yet unexplained. If we practice venesection at the approach of the agony of death, or in those diseases of the valves or orifices of the heart, which oppose a great obstacle to the circulation, the blood will be thick and semi-concrete on flowing from the vein. It is, therefore, to the concretion of the blood in the cavities of the heart, and to their formation, that many cases of sudden death is to be ascribed in certain diseases of this organ.

As to the chemical and vital causes of sanguine concretions, "a kind of crystallization of the blood," the principal are primitive or consecutive inflammation of the internal membrane of the heart (endocarditis), and the introduction of different foreign substances into the circu-

lation, as *pris* for example.* M. Bouillaud is disposed to believe that in febrile and inflammatory diseases in which there is a buffy coat on the blood, there is a strong predisposition to fibrinous concretions of the heart, which strongly resemble, in their incipient stage of development, the inflammatory coat of the blood; and he is convinced of this by the fact, that in almost all cases of concretions which he has met with, not caused by an obstruction to the course of the blood through the heart, they occurred with an idiopathic inflammation of the heart, or with an inflammation of some other organ, which powerfully reacted on the heart, or on the whole of the circulatory system.

Symptoms of Concretions of the Heart.

—The signs of polypiform concretions of the heart, will be modified according to the situation of these substances. They will necessarily produce more or less impediment to the circulation of the blood through the heart, difficulty of breathing, headache, symptoms of apoplexy, &c. When they occupy the right cavities of the heart, which is the most common occurrence, the blood does penetrate into the lungs, but in small quantity, it reflows into the vessels situated behind the obstacle, it engorges all parts, but especially those that are most vascular, as the brain, the liver, &c., hence apoplectic congestions, serous collections, or dropsies in the head, abdomen, and chest. But when the different parts of the body do not receive only a small quantity of blood which has been submitted to the air in the lungs, we observe, to a certain extent, the phenomena of asphyxia. These I have fully described in another work.†

The disorders are almost similar, when concretions obstruct the passage of the blood through the left cavities of the heart. But in this case there will be congestion of the pulmonary veins, which cannot discharge themselves freely into the left

auricle, and hence will arise a degree of dyspnoea, which does not happen in concretions of the right cavities.

Concretions in different parts of the cavities of the heart will impede the circulation of the blood in different degrees, and those connected with the valves will most obstruct it.

The symptoms of concretions are tumultuous beatings of the heart, with obscurity of the bruits which accompany them, a simple or sibilant bruit de soufflet, and sense of suffocation, orthopnoea, anxiety, followed by venous congestions, and, in some cases, coma, stertorous breathing, with or without convulsions, smallness of the pulse, coldness of the extremities. When these symptoms supervene during acute pericarditis, endocarditis, or carditis, it is extremely probable that concretions are being formed in the cavities of the heart.

In chronic diseases of the heart, with habitual dyspnoea or shortness of breath, there are violent fits of orthopnoea, threatening suffocation or instant death, it is almost certain that concretions are forming in the heart.

Prognosis—The prognosis of sanguine concretions of the heart, when these are large and considerably obstruct the course of the blood, is most unfavourable, for they sooner or later prove fatal.

Treatment.—Copious depletion and other antiphlogistic measures, as in pericarditis, the free use of tartarized antimony, and of the neutral salts of soda and potass, which are supposed by some to possess a solvent power on the blood. (Legroux, Stevens, Cameron, &c.) Bouillaud entertains the opinion that recent concretions may be dissolved and carried into the blood vessels; but that when they are organized, that they are incurable. But it remains to be determined whether the use of the hydriodate of potass might not cause their absorption, as it does of other adventitious growths.

DISPLACEMENTS OF THE HEART.

The heart may be displaced in different directions by the pressure of different tumours, by large aneurisms or effusions into the left side of the chest, or by enlargement of the spleen, morbid tumours near the diaphragm, or by abdominal effusions. The passage of the stomach or intestines into one side of the chest may also displace the heart. It has been found in contact with the diaphragm, with the spine, in different parts of the left cavity of the chest, and also in the

* It is ascertained that acids injected into the vascular system of animals coagulate the blood, as they do when it is removed from the body. There are also in the blood the elements of coagulation, when heat or electricity is applied. But what the relation is between artificial coagulation and that which happens under the influence of certain pathological states, is not as yet determined.

† Manual of Medical Jurisprudence, &c. Second Edition. 1836.

right cavity of the thorax. The diagnosis is simple in such cases, and is readily determined by auscultation, percussion, and inspection.

HERNIA OF THE HEART.

This disease has been observed by different pathologists. Vaubonaïs describes a case of a foetus at the eighth month of pregnancy, in which the heart had escaped through an opening in the superior part of the chest, and it hung externally like a medal. Martinez, Besançon, Chaussier, and Breschet, have described cases of hernia of the heart, the accounts of which will be found in the excellent treatise of M. Bouillaud, which I have so freely quoted. M. Breschet has termed the disease *ectopia*, and divides it into three species: 1. Thoracic ectopia of the heart. 2. Abdominal ectopia. And 3. Cephalic ectopia.

PRIMORDIAL VICIES OF SITUATION AND CONFORMATION OF THE HEART.

This class of anormal states are most frequently observed in the foetus during intra uterine life, and are rarely met with at the adult age. I have fully described them under the head of embryonology, in my lectures on the *Physical Education and Diseases of Infants*,* and they do not properly belong to the department of practical medicine, or to a manual of this kind. I shall now but briefly observe, that there may be acardia or absence of the heart, absence of one half of the heart, augmentation of the organ termed bicardia and tricardia; congenital transposition of the heart to the right side or dextrocardia; communications between the right and left cavities of the heart, either in consequence of non-obliteration of the foramen ovale, or of anormal perforations between the interauricular and interventricular partitions. It is to be lamented that all these diseases are incurable.

In the preceding history of diseases of the heart, I have given a much fuller account than can be found in any of our national works on the subject, and I have selected the most valuable information from the latest authors to the period at which I write, May, 1837. I deemed this indispensably necessary, because diseases of the heart are as common as any other in the body, and are generally mistaken for diseases of the lungs, as asthma,

chronic bronchitis, phthisis, &c., and because they are not as yet fully described in any of our works on practice of medicine, or even in our best monographic treatises on cardiac diseases. Thus the works of Dr. Hope, and Dr. Elliotson, which are exclusively devoted to the consideration of this class of complaints, do not comprise the whole of them, and omit many which are now placed before the reader. Influenced by these convictions, I offer a more comprehensive, though more concise account of the nature and treatment of diseases of the heart, than any in our language, with which I am acquainted. I have divided diseases of the heart into structural or organic, and functional, in the same manner as I have those of the brain, spinal marrow, lungs and respiratory organs, the digestive and secretory organs, as the stomach, intestinal canal, liver, kidney, skin, genito-urinary system, &c. The adoption of this arrangement has enabled me to place a most important class of diseases, hitherto neglected, in as clear a manner as those of any other organ in the body. These I might have illustrated by numerous cases from the works of Bouillaud and others, as well as those which have fallen under my own care, both in hospital and private practice, had not the limits by which I am circumscribed, compelled me to be as concise as possible, and to avoid details of cases which might be considered digressions in an elementary work of this description, which is chiefly intended for medical students and junior practitioners.

M. R.

ON THE ENDERMIC AND INNOCULATIVE METHOD,

OR TREATMENT OF DISEASES BY THE INTRODUCTION OF MEDICINE BY THE SKIN, DEPRIVED OF ITS EPIDERM.

Mascagni, in 1797, wrote thus to the illustrious Desgenettes, "The innumerable eminences on the surface of the human body are covered with the gaping mouths of the absorbent vessels, forming at first the tissues of the epiderm, then the net work, branches, and finally the trunks. The internal layers communicate with the external, and thus all parts correspond with the skin. The membranes of the absorbent vessels of the epiderm, and the hairs, are of a finer texture than that of the other parts; they

* See London Medical and Surgical Journal. 1835. Vol i. p. 617, &c.

are therefore better calculated to absorb the substances reduced to a state of vapour. *When medicines are introduced through this channel into the circulation, they certainly produce good effects. We may therefore now hope for the most satisfactory results, from the knowledge of the absorbent system, combined with the practice of medicine; whose progress should be the chief end of our labours, as well as the great object of our desire.*"

Without being acquainted with the anatomy of the absorbent vessels, guided by observation and experience, the ancients subjected medicaments to the absorbent powers of the skin. In the time of Hippocrates, the arteries were supposed to absorb atmospheric air. This first step naturally led to the employment of liquids, and solid agents reduced till they could be absorbed by the pores of the skin. Hippocrates frequently employed medicinal frictions in the treatment of the diseases of females. Diocles brought on vomiting by applying hellebore to the skin. Theophrastus observed that aromatic frictions on the integuments caused eructions, with an odour similar to the aromatic plant employed. Celsus recommended squills to be rubbed on the abdomen for dropsy. Aretæus prescribed aloes in friction. Galen made experiments with various decoctions and with cantharides. The Arabs thought the skin the best channel for the introduction of medicinal substances, and friction was common among the Greeks; but a therapeutical method founded on so imperfect a knowledge of the absorbent functions, and the uncertainty of their effects on account of the epiderm preventing the introduction of the medicaments, could only be had recourse to upon extraordinary occasions. This method fell into disuse for some time, till the erudite works of Cruikshank, Mascagni, Spallanzani, again brought it into notice. Attention was once more paid to the importance of cutaneous absorption, and the possibility of making it a substitute for the intestinal tube, which in a state of irritation would be unfit to receive medicinal agents. Previously to Alibert's experiments, Boyle had observed that aperient substances used as frictions produced the same effect as if taken internally.

Kennedy found that quinine rubbed on the skin proved anti-febrile. Chiarenti and Brera, in Italy, made numerous experiments with medicines employed as frictions. Alibert, Pinel, and Dumeril

confirmed their efficacy. Christien, of Montpellier, extended the limits of this therapeutical method; its progress is due to him; he called it *Iatroleptic*, which refers to the manner of applying medicaments by friction.

Among all the diseases in which the iatroleptic method has proved beneficial, none have shown its efficacy so well as the syphilitic diseases treated by Cirillo's method of friction with mercury; or by Chrestien's friction with a preparation of gold. There are numberless scientific facts to warrant confidence in the employment of medicaments by friction. Fumigations in herpetic and syphilitic diseases, frictions, unctions, baths, lotions, poultices, are in common use; but not collectively united, so as to form a separate scientific therapeutical branch, under the name of external medication. The ancients were well aware of the aptitude the skin possessed for absorbing external substances, but what progress could be made while they were only acquainted with the two vascular systems, the one arterial, the other venous? and the existence of the lymphatic system was hardly suspected. Since Azelli, Mascagni, Lippi, and the researches of Chrestien, Pinel, Alibert, Dumeril, this branch of science has made some progress. It must however have been limited as long as the epiderm was a bar to the introduction of medicaments. Why not sooner have surmounted this slight obstacle?

It is extraordinary that the advantages to be expected from subcutaneous absorption have not been sooner understood; but the human mind ever proceeds by slow and almost imperceptible degrees. Who is not aware that syphilis and vaccine are inoculated when the slightest sore exists, or when there is only a trifling scratch? The effects of the sting of a serpent, of a wound with a dissecting scalpel, are universally known. Among the ancients how frequently death resulted from the wound of a poisoned arrow!

How is it that in England—the cradle of vaccination, the land famed for useful applications—this method, so rational, so certain, has not been employed more frequently? How is it that medical encyclopedists have not consecrated a few pages to call the attention of practitioners to a subject of such deep interest?

It is by the lymphatic and venous capillaries, profusely spread in the thickness of the skin, that absorption is effected. Covered with its epiderm, the

skin has no longer the same absorbing power; and this power is much less than that of the mucous membrane. The method of cutaneous absorption differs but little from that of the absorption of chyle on the intestinal surface, and is not merely an act of simple imbibition analogous to that found in inert bodies.

Once deprived of the protecting epiderm which covers the venous and lymphatic extremities of the periphery of the body, the skin becomes more absorbent; nearly all agents reduced to fine powder or liquid, or to a gaseous state, are immediately absorbed when the epidermic is off the skin; some substances which laid on the skin, when intact produce no effect, are, on the contrary, always absorbed when the epiderm is taken off. Such is the principle of the endermic or innoculative method.

All attempts to render the epiderm permeable by frictions or preparatory applications, are but of little consequence compared to the skin deprived of its epiderm. The important point is to open the venous and lymphatic vessels on the surface of the body, so that they may receive all the substances placed in contact with them.

In 1823, Messrs. Lambert and Lesieur conceived the idea of the endermic method. Before then, Murray had given out that aloes applied to the surface of a blister or seton, produced alvine evacuations. Bally observed narcotism in a child who had moxas applied, composed of salve washed in distilled laurel water. Professor Dumeril innoculated the small pox by applying to the surface of a blister, a thread covered with variolic virus. The same practitioner cured a paralysis of the eyelid by introducing into an incision, extract of nux vomica; but all these facts appertaining to science remained sterile, till Lambert and Lesieur thought of deducing from them a new therapeutical method.

These advantages were fully appreciated at a period when it was supposed that active medicines always produced intestinal irritation; and although there is at present less dread of irritation, there are a great number of circumstances to recommend the endermic method. Are there not morbid states which sometimes prevent the injection of medicaments? May not the intestinal mucous membrane be irritated or inflamed? At other times are we not obliged to seek new channels for the introduction of medicine when the stomach and intestines, accustomed to

the stimulus cease to feel its effect? What is to be done in chronic gastralgia, and scirrhus and cancer of the stomach?

The introduction of active medicaments by the rectum, will be considered as supplementary means in the cases here named; but how many chances against this method; for it is not the rectum sometimes in a state of irritation similar to that of the stomach and intestines, or it is not habitually filled with feces, and consequently unfit to receive or retain the medicaments there conveyed?

When the possibility of conveying medicines to the internal pulmonary surface by inhalation, was given out, the most happy results were anticipated. Was it possible to convey to the lungs, air impregnated with medicinal principles, without destroying its purity? and good air is as necessary as good food. Chloride, aromatic substances, and the vapour of tar have not realized the expectations formed.

How many well founded motives exist for endeavouring to find a new channel for the introduction of medicine; how many good reasons for appreciating the method presented by Lambert, and for confiding to the subcutaneous absorbents, medicines that could not be introduced by ordinary means. When once the epiderm is destroyed, the venous and lymphatic absorbents receive the substances applied, and convey them unaltered, and almost without mixture through the whole extent of the circulatory system. This method is perhaps more simple than any other: if any positive result may be expected from a medicine, it is when the substance shall have been applied on absorbent vessels, and that the digestive powers have no action on it. The greater the progress of chemical knowledge, the greater will be the advantages of the endermic method; as the active part of medicines, freed from the useless mass which surrounds them, may act with greater safety on the tissues.

Why have medicines always something uncertain in their action? It is because they reach a surface ever varying in its condition, or the intestinal mucous membrane is irritated or covered with mucosities, or the stomach and bowels are full. In subcutaneous absorption, the absorbent vessels are always in a free state when recently deprived of their epiderm.

Previously to employing the endermic method, it is necessary to be acquainted with the action of the different agents on the tissues: the caustic agents are not absorbed, because they destroy both the

tissues and the absorbent vessels they touch: then again, absorption cannot take place, even after raising the epiderm, if time be left for the establishment of the pseudo membrane, which is secreted so speedily after the epiderm is taken off.

Before we lay down rules for the endermic method, let us judge of its application in the hands of men whose very name is an authority, after which we shall draw consequences, and establish rules to guide the practitioner.—*Continental and British Medical Review.*

The London Medical AND Surgical Journal.

Saturday, May 6th, 1837.

THE CERTIFICATE SYSTEM.

THE system of granting certificates to students by the various lecturers of the metropolitan schools—a system which has been so long tolerated, notwithstanding its enormities and fraudulent tendency, is at this season in its full and vigorous operation. It is impossible to conceive anything more nefarious than teachers granting certificates of punctual and diligent attendance on their lectures, to those who have scarcely ever been within their theatres. To obviate this manifest evil, and in order to prevent false certificates being granted to inattentive pupils, the Royal College of Surgeons of Edinburgh enacted some time ago, the following regulations:—

“ I. That every private lecturer at this school of medicine, whose lectures are recognized by the College, shall ascertain, at least 20 times in a 6 months' course, and 10 times in a 3 months' course, the actual attendance given by his pupils.

“ II. That he shall do this by calling the name of each pupil at least once a week, causing him to stand up when an-

swering to his name, and entering in a regular roll-book the presence or absence of each individual,—the students, of course, being kept in ignorance of the particular day on which this is to be done.

“ III. That the said roll-book shall be kept according to a form prescribed by the College, and be at all times accessible to the President and Treasurer of the College, who shall examine it at least once during every session.

“ IV. That, at the end of every session, each private lecturer at this school of medicine shall transmit to the President of this College a list of the pupils who, during that session, have attended his lectures, and specify the number of times each has been present when the roll was called.

“ V. That, in granting certificates of attendance, the private lecturers shall use the annexed form, filling up the blanks with words at length, and on no account employing figures: [The form certifies the attendance of the pupil, that the roll was called so many times, and that the pupil was present on so many of those occasions.]

“ VI. That, when a student's certificate of attendance bears that he has been more than four times absent when the roll was called, the president shall intimate this at the foot of that student's letter to the examiners, specifying the branch, or branches, on which the defective attendance has been given, in order that he may be particularly examined upon them. But if a student's certificate bears that he has been absent more than eight times when the roll was called, he shall not be admitted to examination at all, until he has attended another course of lectures on every such department of study. These numbers refer to six months' courses, and one half

of the same numbers to regulate the procedure as to three months' courses.

"VII. That when a student's absence has been occasioned *by sickness*, or any other unavoidable cause, such cause shall be stated in the certificate, by the lecturer; and also in the periodical return to the president, in order that the council may decide whether the student shall, or not, be required to attend *another course* of such lectures before examination."

In framing these regulations, the Royal College of Surgeons of Edinburgh have only done so in imitation of a renowned professor in Gower Street, who, after the experience of several seasons, found that his prosy eloquence in place of having a positive electro-attractive effect, had a negative repulsive tendency, which prompted the learned professor to institute a *roll-call* every morning, which had certainly the effect of collecting all the names, but not the attendance of the body corporate, for one student being authorized, by his comrades during their absence, to answer for them; and, if report can be relied on, friendship went so far, that one student was wont to answer for not less than thirteen of his bed-ridden companions. The only parallel case which has come within our knowledge, and which is so often told for Sir James M'Gregor, is of an officer whose whole supply of linen consisted of three shirts, one of which was marked No. 23, the other No. 33, and the last No. 43.

Certificates, however, continued to be given without the slightest hesitation, although the operation of the roll-call system must have been well understood. A similar attempt was made to elude the vigilance and eagle-eye of James Macartney; but the student on this memorable occasion, who had been in the habit of sending his *surtout* to occupy his seat in the theatre,

on applying for his certificate to the celebrated professor, received a document to the following effect:—

"I hereby certify, that Mr. Terence O'Brien, M'Fuddle's *SURTOUT*, has *punctually* and *soberly* attended my lectures on anatomy and physiology.

(Signed) JAMES MACARTNEY.
Trinity College, Dublin."

THE QUEEN'S HEALTH.

Though the symptoms of her Majesty's disorder have been somewhat abated, no alteration has taken place in the general character of her condition.

There is an absurd report in circulation amongst a certain circle, that her internal ailments have been caused by the imprudent measures which were adopted to suppress an eruptive disease. We do not know what truth there may be in the report of a change of her Majesty's Medical Staff; and it is by no means unlikely that her advisers will have the good sense and discrimination to recommend the most justly celebrated Court Physician, who has so long graced and adorned the halls of the College.

THE ANATOMIST.

LOWER EXTREMITY.

The bones proper to the lower extremity are the femur, the tibia, the fibula, the patella, seven tarsal bones, five metatarsal bones, and fourteen phalanges.

THE FEMUR.

Head, forms nearly two-thirds of a sphere, and is received into the acetabulum, being directed forwards, upwards, and inwards; below its centre is a rough pit for the ligamentum teres, and its junction with the neck is marked by a rough line. With the exception of these parts it is covered by cartilage in the recent state.

Neck, extends obliquely downwards

and outwards from the head to the shaft, which it joins at an obtuse angle; it is flattened anteriorly and posteriorly, and its lower edge is much longer than its upper.

Great trochanter, is continued upwards from the shaft, but does not extend as high as the head, is situated externally, and gives attachment to the *glutæus medius*, *glutæus minimus*, and *quadratus femoris* muscles.

Digital fossa, is situated at the root of the great trochanter, and affords insertion to the external rotator muscles.

Lesser trochanter, is situated posterior and internal to the shaft, and has inserted into it the *psaos* and *iliac* muscles.

Intertrochanteric lines, are two in number, one anterior, the other posterior; as their name implies, they pass (obliquely) from one trochanter to the other.

Shaft, is broad at either extremity, particularly towards the knee, and is narrow and triangular in the centre; it is arched and smooth anteriorly; at its posterior part it is concave, and presents a rough line called *linea aspera*, about the centre of which, and directed downwards, is the foramen for the nutritious vessels.

Linea aspera, is best marked for the central third of the shaft; towards the upper third it bifurcates, one ridge running to each trochanter; inferiorly it also divides into two ridges, which pass to either condyle, the inner one being interrupted where the popliteal vessels pass over it. By these inferior ridges a flat triangular surface of the femur is bounded laterally, which receives the name of popliteal surface.

External condyle, is larger and projects more upon the anterior surface of the femur than the internal, it is also broader and ascends higher upon the shaft.

Internal condyle, narrower than the external; it also descends lower, in order that both condyles should rest upon the tibia in the natural oblique direction of the femur.

External tuberosity, above the external condyle for the attachment of the external lateral ligament of the knee-joint.

Internal tuberosity, above the internal condyle, and more prominent than the external, for the internal lateral ligament and the insertion of the great adductor tendon.

Popliteal groove, between the external tuberosity, and the external condyle; it

lodges the popliteal tendon in the flexed position of the joint.

Trochlea, between the condyles on their anterior aspect, supports the patella when the leg is extended.

Intercondyloid fossa, is situated posteriorly between the condyles.

PATELLA.

Shape, triangular, the base superiorly having the extensor muscles inserted into it, the apex below to which is attached the ligamentum patellæ.

External surface, presents a fibrous appearance, and is convex.

Internal surface, presents two articular surfaces, divided by a prominent edge; the internal surface is the deepest whilst the external is broad and shallow.

TIBIA.

Shaft, is triangular, presenting three surfaces, separated by corresponding edges. The inner surface is subcutaneous, except at its upper part, where the tendons of the *sartorius*, *gracilis* and *semitendinosus* muscles pass over it, it terminates in the inner malleolus; the external surface is covered by the belly of the *tibialis anticus* muscle for its upper extent, and is here concave; inferiorly it is convex, and anterior to support the tendons of the extensor muscles of the toes; the posterior surface presents an oblique line directed upwards and outwards for the attachment of the *solæus*, *poplitæus*, and deep flexor muscles, the nutritious foramen, which is the largest in the body, is a little below this line, and directed upwards. Of the edges, the anterior is most prominent and subcutaneous; the inner is less defined, and the outer is well marked, affording attachment to the interosseous ligament.

Upper or femoral extremity, expanded to articulate with the femur, is convex upon its sides and anterior aspect, being grooved posteriorly.

Tuberosities, are three in number, two laterally, and one anteriorly; the anterior is most prominent for the insertion of the ligament of the patella; the inner is less so, and affords attachment to the internal lateral ligament of the knee-joint, and the *semimembranosus* muscle, and the outer is the least developed.

Superior articular surfaces, are three in number, two for the femur, and one for the head of the fibula; those for the femur are separated by the spine, the internal being oval and deep; the external, circular, shallow, and directed down-

wards and outwards; that for the fibula is behind the external tuberosity, and looks downwards.

Spine, placed between the articular surfaces for the femur, projects upwards, and is bifid at its apex.

Lower or tarsal extremity, is much smaller than the upper and quadrilateral, the anterior edge being convex for the passage of the extensor tendons; the posterior, marked by a groove, for the passage of the tendon of the flexor pollicis proprius muscle; the external presenting a rough triangular surface for the fibula, and the internal terminating in the internal malleolus.

Internal malleolus, is convex and subcutaneously internally, its external or articular aspect being smooth, to articulate with the astragalus, besides giving attachment to the internal lateral ligament of the ankle-joint, by its inferior edge it affords a groove posteriorly for the tendons of the flexor communis and tibialis posticus muscles.

Inferior articular surface, rests upon the crown of the astragalus, it is quadrilateral and concave from before backwards, and joins the small articular surface of the internal malleolus at a right angle.

FIBULA.

Situation, on the outer side of the femur.

Shaft, triangular and twisted, gives attachment to the peronæi muscles by its external surface, to the solæus and flexor pollicis muscles by its posterior surface, and to the extensor muscles by its anterior surface. Its inner edge is well developed to afford attachment to the interosseous ligament, and the nutritious foramen, directed upwards, is placed upon the posterior aspect of the bone.

Head, articulates with the femur by a small circular surface directed upwards and inwards, and affords attachment to the external lateral ligament of the knee-joint, and the biceps flexor muscle by a rough projection situated posteriorly.

Neck, is the small constricted part by which the head is united to the shaft.

Tarsal extremity, presents a large oval process called the external malleolus, about two inches and a half above which the shaft is constricted.

External malleolus, is larger than the internal on a line posterior to which it is situated; by its edge it affords attachments to the external lateral ligaments of the ankle-joint. Its outer surface is con-

vex and subcutaneous, the inner or articular being smooth to articulate with the outer side of the astragalus; above this surface is a triangular rough aspect for the inferior connection of the bone with the femur.

TARSUS.

Forms the posterior part of the foot, the bones which compose it are seven in number, which articulate with each other. It is connected above to the tibia and fibula, below it is hollow, and anteriorly it unites by articular surfaces with the five metatarsal bones. The seven tarsal bones are the calcaneum, astragalus, navicular, cuboid, and three cuneiform.

CALCANEUM, OR OS CALCIS.

Situation at the posterior and under part of the tarsus.

Posterior aspect, elongated to form the heel, presents a smoothness above for a bursa mucosa, and a rough surface below for the insertion of the tendo achillis.

Anterior aspect articulates by a smooth surface with the cuboid bone.

Superior aspect presents two articular surfaces, which support the astragalus; these are separated by a groove, into which ligaments are inserted.

Inferior aspect is irregular, presenting two small tubercles, and two lines for the attachment of muscles and ligaments.

External aspect presents a small tubercle for the insertion of the middle external lateral ligament of the ankle joint it is also slightly grooved for the passage of the peronæi tendons.

Internal aspect presents a narrow edge for the attachment of the internal lateral ligament.

ASTRAGALUS.

Situation, at the upper and middle part of the tarsus, between the malleoli at either side: the tibia above, and the calcaneum below.

Crown, broader anteriorly than posteriorly; presents three articular surfaces; one large, superiorly to articulate with the tibia; the others, one on either side, to articulate with the malleoli.

Head, convex and smooth, is directed forwards and inwards, and is larger than the concavity of the navicular bone with which it articulates.

Neck, the contracted portion between the crown and the head is rough, for the attachment of ligaments.

Inferior aspect presents two articular surfaces for connexion with the calcaneum;

these are also separated by a groove, from which ligaments pass to the groove in the calcaneum.

Posterior aspect is narrow, and presents a groove for the tendon of the flexor pollicis longus muscle, and a pointed eminence for the posterior external lateral ligament of the ankle.

NAVICULARE.

Situation, middle of the tarsus.

Posterior aspect is smooth and concave, to articulate with the head of the astragalus.

Anterior aspect presents two vertical lines, which divides it into three smooth surfaces for articulation with the three cuneiform bones, and, in general, a small articular surface, where it touches the cuboid bone.

Tubercle, situated inferiorly for the insertion of the tendon of the tibialis posticus muscle.

CUBOIDES.

Situation, outer and anterior part of the tarsus.

Upper surface, flat and rough for ligaments.

Lower surface, tubercular behind, for the calcaneo-cuboid ligament, and presenting a groove anteriorly for the tendon of the peronæus longus muscle.

Posterior surface, smooth and concave transversely, to articulate with the os calcis.

Anterior surface presents two articular surfaces; the external triangular to articulate with the metatarsal bone of the little toe, the inner square for the fourth metatarsal bone.

External surface narrow and free.

Internal surface presents a posteriorly small articular surface for the naviculare, and anteriorly a second, which is larger, to articulate with the outer side of the external cuneiform bone.

INTERNAL CUNEIFORM BONE.

The largest of the three articulates behind with the scaphoid; before, with the first metatarsal bone; externally, with the middle cuneiform and side of the second metatarsal bone.

Tubercle is situated inferiorly for the insertion of the tendon of the tibialis anticus muscle, and part of the tendon of the tibialis posticus.

MIDDLE CUNEIFORM BONE.

The smallest articulates behind with the scaphoid bone; before, with the se-

cond metatarsal bone; externally, with the external cuneiform; and internally, with the internal cuneiform.

EXTERNAL CUNEIFORM BONE.

Articulates behind with the scaphoid bone; before, with the third metatarsal bone; internally, with the middle cuneiform and side of the second metatarsal bone; and externally, with the cuboid and fourth metatarsal bone.

METATARSUS

is the middle part of the foot, and is composed of five long bones placed between the tarsus and the toes.

FIRST METATARSAL BONE,

the shortest and thickest, is convex above and concave below.

Posterior extremity is smooth and oval, to articulate with the internal cuneiform bone.

Anterior extremity, round, to articulate with the great toe. The under surface of this extremity articulates with two sesamoid bones, and receives the insertion of the tendon of the peronæus longus.

SECOND METATARSAL BONE,

the longest.

Posterior extremity articulates with the three cuneiform bones, and also with the third metatarsal bone.

Anterior extremity presents a round head, for articulation with the second toe, which is separated from the shaft of the bone by a groove.

THIRD METATARSAL BONE.

Posterior extremity articulates with the third cuneiform bone.

Anterior extremity resembles the second, and articulates with the third toe.

FOURTH METATARSAL BONE.

Posterior extremity articulates with the cuboid bone, and by its inner side with the third cuneiform.

Anterior extremity resembles the second, and articulates with the fourth toe.

FIFTH METATARSAL BONE.

Posterior extremity articulates with the cuboid bone by a surface directed obliquely upwards and outwards.

Anterior extremity resembles the second, and articulates with the fifth toe.

PHALANGES, OR TOES,

are composed of fourteen bones, three to each toe, except the first, which has only two.

FIRST PHALANGES.

Shape, convex above, concave below, and the longest.

Anterior extremities, convex from above downwards, and concave laterally; form ginglymoid articulations with the second phalanges.

Posterior extremities are large, and present rounded concavities for the heads of the metatarsal bones.

SECOND PHALANGES.

Anterior extremities resemble those of the first phalanges.

Posterior extremities, concave from above downwards, and convex transversely; articulate with the first phalanges.

THIRD PHALANGES.

Anterior extremities, pyramidal in form, support the nails on their upper surface, and are tubercular and porous on their under surface.

Posterior extremities resemble the posterior extremities of the middle phalanges.

SESAMOID BONES

are uncertain in development; two are generally found at the base of the first phalanx of the great toe, and one at that of the fifth toe. They are also frequently developed in the tendons which cross the sole of the foot in those situations where they are subjected to much pressure.

ANIMAL MAGNETISM.

[We shall now conclude our notice of the researches of the Commissioners appointed by the Faculty of Medicine at Paris.]

One of the commissioners had a nervous attack, characterised in particular by excessive coldness of the feet. M. Deslon magnetized him, and put his own foot near one of the commissioner's, but without raising the temperature of the latter. The patient was then placed near the fire, and quickly recovered; but did not experience any effect of the magnetism.

Another of the commissioners, M. Franklin, being prevented from attending with the rest, was magnetized by M. Deslon at his own house, in the presence of a numerous company. Several patients who accompanied M. Deslon, were affected in the same manner in which they had been usually acted on when magnetized on former occasions; but neither M. Franklin himself, his father and mother, his secretary, an American officer, and a lady, who were present, experienced any effects from being magnetized. Children, who were not sensible of what was going on, were not found to be affected.

The commissioners were directed to another magnetizer, M. Jumelin, who differed in his views from Messrs. Deslon and Mesmer, and regarded the magnetic fluid as identical with calvric. He performed experiments in their presence on eleven patients. Of these, "eight men and two women felt nothing. One only, a female, on being magnetized at a little distance, without being touched, declared she felt a sensation of warmth. When M. Jumelin moved his hand before her face, presenting the extremities of his fingers toward her, she felt as if a

flame passed over her. Magnetized in the regions of the stomach and the back, she felt the same heat in those situations. At last, she declared that she felt a general warmth over the body, and a pain in the head. The commissioners suspecting that these effects were due to imagination, blindfolded her, and then magnetized her; in which circumstances the phenomena no longer corresponded to the parts to which the magnetic applications were directed. Magnetized over the stomach and the back, the patient felt heat in the head, and pain in the right eye and the left ear. The bandage was then removed from her eyes, and M. Jumelin applied his hands to the hypochondria, upon which she said she felt heat there, and, in a few minutes time, that she was going to be ill, and ill she was accordingly. When she had completely recovered, her eyes were again blindfolded. M. Jumelin was taken out of the room, and the woman was made to believe that she was being magnetized. The effects were the same as before; the same heat, the same pain in the eyes and ears, although no action whatever was exerted on her. She declared, in addition, that she felt heat in the back and loins. At the end of a quarter of an hour, M. Jumelin magnetized her over the stomach, but she felt nothing, and then over the back, with the same result. Her sensations diminished instead of increasing; for although the pains in the head remained, the heat in the back and the loins ceased." M. Jumelin did not recognize any distinction of magnetic poles; and as he produced the same effects as those who did, it is quite evident the distinction is groundless.

"A servant of M. Jumelin had then his eyes bandaged, and they persuaded him he was being magnetized. Immediately he felt a general warmth, and movements in the abdomen. The head began to feel heavy, he gradually became very quiet, and seemed to be on the point of falling asleep. His eyes being then uncovered, and the iron rod pointed to his forehead, he said he felt a pricking sensation there. When his eyes were again covered, although the rod was still presented, he said he felt nothing. Finally, the rod was taken away altogether, and he was then asked if he felt any thing in his forehead. He replied that he felt as if something was going backwards and forwards over it.

"M. B., a gentleman well educated, particularly in medicine, on being blind-

folded, presented the same results, experiencing effects when not acted upon, and often experiencing nothing when he was acted on. For ten minutes before he was magnetized at all, although he thought they were acting on him, he felt a heat in the loins, which he compared to that produced by a stove. His resorting to this comparison, proved that the sensation was a powerful one, and it is equally plain that it was indebted for its origin to imagination alone."

The commissioners instituted a great number of experiments, varied in every possible form; and the only difference observable was such as was due to a more or less excitable imagination. M. Sigault himself relates that on one occasion when it was determined to magnetize him, in order to overcome his incredulity, he felt at the moment they were going to touch him, a constriction of the chest, and palpitations of the heart; but having summoned his self-possession, they employed all the gestures and proceedings of magnetism, without producing any impression.

The magnetizers affirmed that when a tree was magnetized, all who approached it would feel the effects of the secret agent more or less severely; in some instances, even to the loss of consciousness, or to convulsions. M. Deslon informed the commissioners that the experiment would succeed, if performed with a person of a temperament liable to be affected by the magnetic fluid. They requested him, therefore, to choose a person whom he had previously known to be susceptible of magnetic impressions. He accordingly took down to Passy a boy about twelve years of age. They conducted M. Deslon to an apricot-tree, which stood in the garden by itself, in order that he might magnetize it; the boy being left in the house, in the care of a person who never quitted him. They wished that M. Deslon should not be present at the subsequent experiment; but he declared that it might fail if he did not look at the tree, and point his cane towards it, in order to increase its action. However, they kept him at as great a distance as they could, and placed themselves between him and the boy, to prevent signals passing between him and the operator. The boy was then brought out, with his eyes bandaged, and conducted successively to four trees which were not magnetized; each of which he was made to embrace for about two minutes. M. Deslon was directing his cane

all this while, towards the tree which really was magnetized.

"At the first tree, which was twenty-seven feet distant from the magnetized one, the boy declared that he perspired profusely. He coughed, expectorated, and complained of a slight pain in his head. At the second tree, thirty-six feet from the magnetized one, he felt stupefied, with the same pain in his head. This pain and stupefaction were much increased at the third tree; and he said he thought he was approaching the magnetized tree. He was, however, thirty-eight feet from it. Finally, at the fourth tree, which was eighty feet from the really magnetized one, the boy fell into a crisis. He lost his senses, and his limbs became stiff. They laid him on the turf at a little distance, and M. Deslon brought him to.

"The result of this experiment was quite unfavourable to magnetism. M. Deslon endeavoured to explain it by saying that all the trees naturally possessed magnetic properties, which were besides strengthened by his presence. But if that were the case, a person susceptible of the magnetic influence could never walk in a garden without the risk of falling into convulsions; and if M. Deslon's presence were so powerful, it is a wonder that it had no effect on the boy while in the coach in which they went down to Passy together."

On another occasion, "a woman, with her eyes bandaged, was taken into a room by three commissioners, and was persuaded that M. Deslon was going to magnetize her. One of the commissioners then called on that gentleman to begin; although, of course, he was not present. In about three minutes time the patient had a nervous rigor, pain at the back of the head, and then in the arm, with a feeling of uneasiness in the hands. Her limbs became rigid, she struck with her hands, rose from her seat, and stamped with her feet. The crises, in short, was well marked. Two other commissioners were in a separate room with a young lady subject to nervous affections. Her eyes were left uncovered, but she was placed opposite to a closed door, on the other side of which they pretended M. Deslon was magnetizing her. A minute had scarcely elapsed before she had a rigor, followed by chattering of the teeth, and a sense of general heat. In three minutes the crisis was complete. The respiration was hurried. Her arms were stretched out behind, twisted strongly,

and the body was bent forwards. She bit her hand with sufficient force to leave the marks of her teeth imprinted on it."

The first of these two women was made the subject of another experiment, with what is called the magnetised cup. "This is performed by magnetizing one among a number of cups, and presenting them all successively to a patient susceptible of magnetism. When he arrives at the particular cup, he ought to fall into a crisis, or at any rate to exhibit very marked effects. The woman was taken to the Arsenal, where M. Deslon was. She had got no further than the antichamber when she fell into a crisis, although she had not yet seen either the commissaries or M. Deslon, but she knew she was going to see him, and that was enough to excite her imagination. When the crisis was over, she was taken into another room, where several porcelain cups, which had not been magnetized, were presented to her. At the second cup she began to be affected, and at the fourth fell into another crisis. In a little while afterwards, having asked for drink, it was given her in the magnetized cup. She drank quietly, and said she felt much better. Magnetism and the cup, therefore, failed of effect, for the crisis was calmed instead of being exasperated."

The experiment was varied in another way. "While M. Majault was examining this woman's eyes (which were affected with cataract,) the magnetized cup was held behind her head for twelve minutes, without her being aware of it, or experiencing any effect from it. On the other hand, the commissioners having retired, and different persons, unacquainted with magnetism, coming about her, convulsions recommenced. She was told that no one was magnetizing her; but she replied, 'If you were not doing any thing, I should not be in the state in which I am.' She knew that she had come for the purpose of being submitted to experiments, and so excited was her imagination, that the approach of any person, or the slightest noise, attracted her attention, excited the idea of magnetism, and the convulsions were renewed.

"A young lady, twenty years of age, was deprived of the power of utterance by the magnetic process; so that for the space of a minute she could not articulate sounds, notwithstanding all her efforts." Sight was necessary in this instance, for they could not succeed when she was blindfolded; and its im-

portance, as an avenue through which the imagination is reached, was likewise seen in the following case: "A woman who had but recently come under M. Deslon's care, having, when recovering from a crisis, encountered the look of one of his pupils, was for a long time haunted by it. The eye appeared to be constantly before her, and looking at her, and for three days kept constant possession of her imagination, whether sleeping or awake."

Mademoiselle B., who has already been mentioned as having been magnetized at Passy, was again magnetized at Paris, by M. Deslon himself, through a paper-screen. The latter could present no obstacle; for the magnetic influence is said to pass through wooden doors, stone walls, &c. At Passy she fell into a crisis after three minutes; but in Paris she was magnetized for half an hour, without any crisis at all. The cause of this difference was that at Passy she knew she was being magnetized, while at Paris she knew nothing about it. The magnetizer then advanced from his concealment, and magnetized the young lady with direct, instead of opposite poles, which, according to the theory of magnetism, ought to have produced no effect. "Nevertheless, in about three minutes, she felt a general uneasiness, and a difficulty of breathing, followed by hiccough, chattering of the teeth, constriction of the throat, and severe pain in the head. She was restless on her chair, complained of pains in the loins, sometimes struck the floor quickly with her foot, and then stretched out her arm behind her back, twisting it forcibly; in a word, the crisis was complete, and perfectly characterized." All this occurred in about twelve minutes. Imagination not only put her into this crisis, but likewise took her out of it. "The magnetizer said it was time to finish, and presented to her his index fingers, in the form of a cross. There, be it observed, the poles were still direct. He had, therefore, made no change in the process, and therefore the same treatment should have produced the same results. On the contrary, however, the heat and pain of the head were removed; she became calm; all the symptoms disappeared one by one, and in three minutes Miss B. declared she was as well as ever.

Many causes contributed to augment the crises, in the public treatment of patients. Of these, very potent ones were touchings and pressure over various

parts of the body,—the epigastrium, the hypochondria, the colon, the nervous centre of organic life, and, above all in females, over the regions of the uterus and ovaries. In a numerous assembly, the effect of imitation is very great, and impressions and motions are communicated from one to another with great rapidity. We have already seen one notable example of this, in the case of the young people at the church of St. Roch. Another remarkable instance was that of the "trembleurs des Cevennes." Marshal de Villars, who was personally acquainted with all the circumstances, writes as follows: "I have seen on this occasion what I could not have believed if it had not passed before my eyes, a whole town, in which all the women and girls, without exception, appeared to be possessed by the devil. They trembled, and prophesied publicly in the street. One had the boldness to do so before me for a whole hour. But of all these follies, the most surprising was that which was told me by the bishop of Alais, and which I communicated to M. de Chamillard in the following terms. M. de Mandagors, the mayor of Alais, has just done an extraordinary thing. He is sixty years of age, of sedate manners, and much talent, having written and published several works. A prophetess, about twenty-seven years of age, was arrested and brought before him. He questioned her before several ecclesiastics. She replied with a modest air, exhorting him no longer to torment the true children of God; after which she spoke to him for the space of an hour in a strange language, of which he did not understand one word. M. d'Alais had the prophetess put into confinement. After several months, as she appeared to be cured of her hallucination, by means of his care and advice, for he visited her occasionally, she was restored to liberty; and of this liberty, and of those which M. Mandagors took with her, the result was that she became pregnant. M. Mandagors affirms that it was at the command of God he was intimate with this prophetess, and the child which should be born would be the true Saviour of the world. The bishop wished me to have him arrested; but I think that in the midst of fools, all that relates to a fool of such consequence should be done with as little noise as possible; especially as, except on this particular subject, he is a very sensible man; just as Don Quixote was very reasonable, except when chas-

valry, was in question. He was committed to the care of his children, in one of his houses, and the prophetic was again shut up.

Persons in a state of crisis, often seek each other by a kind of sympathy; mutually solacing each other by contact, and remaining together for a long time, in a state of calmness and quietude. The following is an instance of one patient magnetizing another. "A young man who was frequently in a state of crisis, was at those times dumb, quietly walking through the rooms, and frequently touching the patients. This sometimes produced a crisis, which he regularly conducted to its termination, without allowing any interference. When he recovered to his ordinary state, he talked, forgot all that had taken place, and no longer knew how to magnetize."

In general patients in a state of somnambulism, do not answer questions put in a strange language; but the following is an instance of the contrary: "A very talented and well educated physician, had a patient who, when in somnambulism, exhibited the most surprising phenomena. He understood him when he spoke in Latin, Greek, and English. One day he read to his patients some lines in English, 'What do you think I know of your gibberish?' replied he. 'Why,' said the magnetizer, 'I have frequently spoken to you in that language, and you have answered me.' 'If that was the case,' rejoined the patient, 'It was your thoughts I understood, and not your language.'"

Dr. Bertrand gives several remarkable instances of seeing without eyes. One of the most striking was that of "a patient in somnambulism who, though his eyes were evidently closed, did not indicate with less precision the place where a ring was concealed, which I had taken from his finger, and given to a lady who was present. What rendered this experiment more conclusive was, that the husband of this lady took the ring from her (unknown to me) and put it in his pocket. It was there that the patient declared he saw it, and persisted in the declaration, notwithstanding my assurances that it was not; for I thought the lady had it still." Petelin relates the case of a lady, who told the hour by a watch concealed in the hand of her husband; described an antique medal in closed hand of another person; and recognised a letter addressed to her which was shut up in a box. Another patient in somnambulism,

is said to have described the study of one of the doctor's present, situate in a distant city, telling him the relative position of the books, and a skull which it contained.

Animal magnetism certainly did not do all that was claimed for it. It was put forth as a means of "universal cure and preservation;" which amounts to nothing less than a magnetic elixir of immortality. It becomes us, however, to interrogate nature for ourselves, and not to be misled by her interpreters. Tried by this test, animal magnetism did not prove a universal remedy; but it certainly produced some very curious effects. These effects have come before us in the course of these papers. Some of them are well established (convulsions, for instance); others are doubtful, particularly the curious state called somnambulism, of which several instances have come before us, in which patients have been said to see without eyes; to talk without consciousness; to describe accurately places they had never seen or heard of; and to foretell future events. Those who wish to prosecute the subject further, will find ample means of so doing in the work from which we have translated so largely, "Dr. Bertrand, on Animal Magnetism in France," in which the whole subject is investigated in all its branches and all its bearings.

CASE OF NÆVUS CURED BY PUNCTURE.

By EDWARD DOUBLEDAY, Esq.

The child of Mrs. —, was brought to me at the beginning of November, 1834, with a diffuse swelling between the eyes, encroaching upon the left orbit, and of the size of a large nutmeg. On applying pressure, the tumour almost disappeared; but the moment the finger was removed, it returned to its former size. The mother stated, the first time she saw her child after it was born, she observed a *bruise* between its eyes. Five weeks after this, she noticed a small swelling, and at the expiration of three weeks more, making altogether two months from the birth of the child, it had acquired the size I have stated. The case presented a good example of an *increasing* *nævus* situated in the cellular substance. On the 6th of January, 1836, I introduced a couching needle into the centre of the *nævus*, and moved it from

side to side, so as thoroughly to break down the net-work of vessels. This operation was repeated on the 21st of February, 27th of March, 1st of June, 8th of August, and on the 1st of September, 1835. There was not any diminution of the tumour until after the third operation, after which it gradually decreased in size, although, I beg particularly to observe the *nævus* did not totally disappear until upwards of twelve months after the first puncture.

I have only further to observe, that I believe I performed the operation more frequently than was necessary. It is length of time that is required, and it will be important to observe the *dates* in this case.

I need hardly out point the advantages of this mode of removing *nævus* over excision and the ligature; it is only necessary to recal to mind the hæmorrhage induced by the first of these operations, the pain inflicted by the second, and the scar which results from both.—*Op. cit.*

REPORT ON THE ATMOSPHERE OF TUNNELS,

FOUNDED ON CHEMICAL ANALYSIS.

The Leeds and Selby Railway Tunnel, in which the experiment have been made, is 700 yards long, 17 feet high, and about 22 wide. It inclines 1 foot in 300, and is provided with three ventilating shafts, made originally in excavating the tunnel. They are respectively, 23, 22, and 19 yards deep, measuring from the top to the floor of the tunnel.

No fire or machinery is used to promote the ventilation of this tunnel. I have no hesitation, however, in expressing my conviction, that the air it contains is not injurious to the health of passengers, being renewed sufficiently often by the currents which always prevail in it, to preserve a wholesome atmosphere. The following are the reasons that have induced me to adopt this opinion:—

1. The examination of numerous specimens of air, procured from the tunnel under every variety of circumstances, by an assistant, who made observations there for a week according to the directions I had given him, has shown me that the amount of carbonic acid communicated to the air by the locomotive engine is considerably less than one per cent.,—an amount too trifling to be taken into consideration, as capable of affecting the

health of passengers in the railway coaches during their progress through the tunnel.

2. If the average amount of coke consumed in each trip within the tunnel be calculated; and the volume of carbonic acid it produces be compared with the bulk of the air in the tunnel, we arrive at the same conclusion as by the experiments referred to.

3. But the carbonic acid must not be considered as equally diffused throughout the whole of the air in the tunnel. From the circumstances under which it is produced, it is necessarily at an elevated temperature and mixed with a large quantity of moisture; and though its temperature may instantly be reduced on coming in contact with the air, still the specific gravity of the great mass of the air in which it is enveloped is less than that of the rest of the air in the tunnel, and it floats principally above the roofs of the coaches till it escapes. The heat and moisture more than counterbalance any increased density from the carbonic acid, and numerous researches have shown that very heavy gases do not readily separate from air when they have been intimately mingled with it.

4. The temperature of the air in the tunnel, during the week that my assistant conducted his examination, &c., did not differ much from that of the external air; the greatest difference observed did not exceed six degrees. Its temperature is more uniform than that of the external air. On one occasion, the temperature of the air at the top of the deepest shaft rose, in a few seconds, from thirty-seven to forty degrees, as the engine passed and the vapour ascended from it, and fell as quickly again to thirty-seven degrees as the vapour escaped.

5. No impurity was detected in any of the specimens of air I received, except the carbonic acid, which, as already stated, bears a considerably smaller proportion than 1 to 100.

I may add, that I have been disposed to take a favourable view of the ventilation of tunnels generally, notwithstanding they should be longer than that under consideration; though local peculiarities may at times require special arrangements.

D. B. REID, M.D.

Lecturer on Chemistry.
Edinburgh, 13th March, 1837.

FAMILY CORRESPONDENCE.

Kilballymacollogne, Blarney,
Nov. 1836.

My Dear Tom,—I can plainly perceive from your agreeable and sensible letter of the —, that you have had a good deal to contend with in the selection of a school, and particularly of a good hospital. I hope you were not in a hurry, and that you made every enquiry about the men you had to deal with, before paying away your money; upon this head I am very serious, and I conceive it a most unfortunate thing that the honourable member for Finsbury was so much engaged as to afford you but one interview. I think you should have written to him, and asked his opinion about the Charing Cross hospital, as you could not see him: but “there is no help for spilt milk” now that they have the money in their clutches. The Howship you mention I never heard of, nor any of the gentlemen who were present at his lecture, except Mr. Van Butchell, who I hear is a black, and wears large mustachios. Enquire if the Doctor Goodling is the same Goodling who was an apothecary in St. Martin’s Lane some years ago, when I was in London, and who delivered the women of either five or six children at one lying-in, and of whom it was said in Bell’s Life, rather chimerically, that they were “all alive and kicking?” If so I know a relation of his a very decent person, though in humble life, who I am sure will give me an introduction for you to *Ben* as she calls him; but after all, the best introduction to all such people is the *pecunia*, or as old Monro the son used to call it the “baw-bees,” and Sir Astley Paston Cooper, “the tin.”

From what you say of Greville Street School, it sounds well, and is certainly cheap in comparison with the unreasonable and exorbitant charges of the others. I observe in the prospectus that one of the *professors* is a *(antab*, and another an *Oxon*; is the school on this account in any way connected with Oxford or Cambridge? Make enquiry of the Dean of the Faculty, and let me know in you next.

The lectures on comparative anatomy being delivered gratis, must have been a great temptation to you to enter.

Although my dear Tom I have freely spoken my serious apprehensions to you about the course you have adopted in reference to the Charing Cross Hospital,

yet don’t let any thing I have said, make you relax in your studies.

The introductory lectures are just what I would have anticipated, indeed, in my days few pupils attended the schools until all such trashy catch-pupil orations had terminated; and old nosey Carpuce, as we then used to call him, as the first who made a nose after Taliacotius, never gave one, saying it was nothing but a “flash in the pan.”

What you say of Doctor Charpie’s accent you would have soon got over, I would advise you occasionally to hear him, as it is of importance your ear should be accustomed to the Scotch brogue; I am surprised that you say our countryman Quain has lost *his* brogue, for it is seldom we lose it so late in life, and when I saw his brother Jones last summer, he had a fair smattering of it, and was the same unaffected Patlander as ever. I am glad you had nothing to do with St. George’s, for I heard from a private source that a great deal of low intrigue was daily carrying on by the medical men of that hospital, and whenever this is the case, a bad example to youth is not only set forth, but their professional education must also materially suffer.

The conduct of sir Everard Home who was their lord and master is quite enough to stamp its character as a place of education, and the gratis lectures I see advertised to be given there, must be a trap to snaffle the unwary. I wonder you did not enquire about the Middlesex Hospital! The name of Mayow is known to all Europe as a great physiologist, for his experiments on respiration; and Mr. Tuson who ground me up for the college of surgeons, and who must now be an experienced old practitioner, also enjoys a great celebrity for his contributions to medical science, particularly for his dissected plates which I was most fortunate enough to pick up a few days ago for one sixth of their first cost, and will send them to you by the first opportunity. Tell him who your father is, and he will soon remember me. Pat was out on the 20th and 21st and bagged seven brace and a half; Ponto was as steady as usual, and Fox has much promise. Aunt Sarah desires me to say the shopkeepers in London must be a very impudent set, she is quite in a fidget on account of the death of her black Tabby, which departed this world last night from sheer obesity. I have been dreadfully tormented by old Mrs. Shannahan, who has an unfortunate pain in the upper jaw, which she swears

is the "Tic" although as you are aware she has not a sound tooth in her head. She has taken up this idea in consequence of having read Sir Henry Hallford's description of it in, as she calls them, his "*beautiful orations*." I begged her to have one of her molars out, but she says I know nothing about it, and desires me to request you will consult Sir Henry. I suppose he is always to be found at Windsor attending the queen, and you must enquire what fee he expects; as his advice cannot be worth more than five guineas.

See about this my dear Tom as quickly as possible: let me hear from you soon. I approve highly of your joining the scotch student.

I remain your affectionate father,
Peter—

PROPOSED REDUCTION OF FEES

AT THE MIDDLESEX HOSPITAL.

Sir—The interest which an old pupil takes in the fate of his school will I hope induce you, to insert this letter in your independent journal. *Independent* I venture to call it, because you have not yet like your contemporary come forward as the *hireling* of any particular school of medicine, nor do you countenance the frauds and hypocrisy of any parties of medical men. I could not help feeling vexed at the severe blow which the Middlesex Hospital got the last two sessions by the prodigious decrease of the number of pupils, in consequence of the North London Hospital admitting pupils at a *very reduced price*. This cannot be denied, for it would be absurd to suppose, that a few dramatic or rather tragic performances in an operating theatre, or an exhibition of unparelled doses of kresote or carbonate of iron by the pound, would induce a sober minded student to prefer the wards of that hospital to all the advantages of the Middlesex. I have therefore great pleasure in hearing, that the officers of the Middlesex contemplate to compete with the North London, and if they reduce the admission fee equally low as the Gower-street company, I hesitate not to assert that they will receive the same number of pupils as in former times—Indeed from the extravagant demand for hospital attendance in this metropolis, I am fully persuaded, that ere long, the fees

of all of them must be greatly reduced—
CHIRURGUS.

Foley Place, May 1st. 1837.

P.S.—Since writing the above, Mr. H. has called, and informed me, that the wisacre's of Westminster are seriously talking of lowering their price.

REVIEWS.

A Translation of the New Pharmacopœia of the Royal College of Physicians of London with Notes and Criticisms. By G. F. Collier, M. D., Member of the Royal College of Physicians of London, &c. Royal 8vo. pp. 272. Published by the translator, Spring Gardens.

A Translation of the Pharmacopœia of the Royal College of Physicians of London, with Notes and Illustrations. By Richard Phillips, F.R.S. L. & E. By Permission. 8vo. p. 392. London. 1837. S. Highley.

The translator of the first work is most favourably known for his great classical acquirements which are very apparent by his accurate edition of Celsus and other medical classics. He is therefore particularly well qualified for the task, he has undertaken, and this he has not only executed with great fidelity, but enriched the original by numerous practical illustrations. These he has inserted in side notes, under the head of cautions. Thus after the translation of the formula for preparing the hydrochlorate of morphia are the following remarks.

"Incompatible with astringents containing tannin and gallic acid, which give precipitates with all the salts of morphia. — *Vide* Acetas Morphiæ.

This salt is uniform in its constitution, but the acetate of morphia varies. Besides, it has another advantage over the acetate, in not being deliquescent; whereas the neutral acetate is decomposed by water.

Formula for Syrup. R Morphiæ Hydrochloratis, gr. ij. Syrupi, f3iv. M.

The dose,—a tea-spoon full occasionally, when the cough is troublesome, or two tea-spoons full and upwards for an anodyne dose.

The sulphate of morphia was considered by the French physicians who used it as nearly equal in strength to that of the acetate, but the muriate is thought to be stronger.

N.B. Most of the patent preparations of opium are made with an excess of

acid ; and therefore are less liable to decomposition than the neutral acetate. This observation does not apply to Batteley's solution (containing very little spirit) which has no more acid in it than the laudanum itself, as far as the editor is able to judge from experiments frequently repeated ; and he confidently adds, that if the dispenser be curious in selecting his opium, and giving it age before he use it, he will seldom want any chemical substitute for common preparations.—*Vide Tinct. Opii.*

Liquor Morphii Citratis (Dr. Porter). R Opii crudi optimi, 3iv. Acidi Citrici (crystal), ʒij. These are bruised in a mortar, and a point of boiling distilled water being poured on, they are intimately mixed, and macerated for twenty four hours, after which the solution is strained.

Braithwaite's Black Drop. Take Opium, lbss. Verjuice, Oij. Nutmegs, ʒiiss. Saffron, ʒss.

Boil to proper thickness ; then add, sugar, ʒiv. and of yeast, two table-spoons full. Macerate near the fire for six weeks, then expose to the air until it becomes a syrup ; lastly, decant, filter, and bottle it. About thrice as strong as laudanum."

Another specimen of Dr. Collier's will be sufficient to show the value of his notes and criticisms. After describing quina he thus proceeds :—

Quina Disulphas—Disulphate of Quina.—"These are the common crystals of commerce (formerly called sulphate of quina, and now called disulphate.) When this is triturated with diluted sulphuric acid, it forms a white magma, and, by the addition of more acid, it dissolves. On evaporating the solution, it yields crystals of the true neutral sulphate.

Incompatible with alkalies, alkaline carbonates, and with the usual precipitants of sulphuric acid, &c.

Crystals,—needle-like, pearly, flexible, silky, like asbestos, united in radiated flakes, and excessively bitter.

Be careful not to carry the desiccation too far, or the crystals will fall to powder."

Quina Draughts.—"R Quinæ Disulphat. gr. ss.

Acid. Sulph. dil m ij.

Aquæ destillat. f3vj.

Syrup. Aurantii, f3j. M.

In dyspepsia as a stomachic."

Tonic Pills.—"R Quinæ Disulphatis, Zinci Sulphatis, aa gr. j.

Extract. Anthemidis, q. s. ft. pil.

Every two or three hours in the intervals of agues."

Dr. Sadillot's Febrifuge Pills.—"R Quinæ Disulphatis, gr. xij.

Opii Pulv., gr. iij.

Confect. Op., gr. x. val q. s. for twelve pills: one every hour or two, in the intermission of ague.

Mr. Philip's translation contains a vast deal of chemical illustrations effected by diagrams which will be useful to all students preparing for examination at Apothecaries Hall, as well as to practitioners who wish to prepare some of their own official medicines. But the work is much less diffuse than the former on the medical uses of the different preparations. Thus both works have their peculiar merits.

Dr. Collier's translation is ably executed and a most valuable book to the medical practitioner and student. Mr. Phillip's translation is executed with accuracy and is a most useful work to medical students, and practitioners, as well as to practical chemists.

A Practical Compendium on the Diseases of the Skin, including a particular consideration of the more frequent and intractable forms of these affections, with Cases. By Jonathan Green, M.D. Second edition, 8vo. pp. 371 ; two plates London 1837. Whittaker and Co.

We are happy to observe a second edition of this useful work in so short a period as a year, as it proves the estimation in which it is held by the profession. It is decidedly the most concise yet comprehensive and latest account of diseases of the skin in our language. Dr. Green has laid the best and latest foreign productions under contribution ; and has introduced two coloured plates illustrative of the more common diseases of which he treats. Another and a strong recommendation in favour of this work is, that it is the cheapest on the subject. The author explains his additions to this edition in the following words :—

"The favourable way in which my practical compendium was received by the profession, and the sale of the first edition within a year from the time of its issuing from the press, induce me to give it a second time to the public, in a corrected and amended form. The chief addition made to this second impression consists of the back and front view of the figure, upon which, with the aid of a skilful draughtsman, I have endeavoured to exhibit some of the most characteristic appearances presented by a few of the more

frequent or remarkable diseases of the skin.

"For the term *Porriga*, which embraces alike impetiginous and eczematous eruptions of the scalp, I have substituted that of *Favus*, in conformity with the latest and best authorities on the continent.

"The additional experience I have had in the treatment of the skin diseases since the first edition appeared, has only confirmed me in the general correctness of the pathological views and therapeutical principles I then advocated. My confidence in the vapour and fumigating baths, as ulterior agents in subduing these diseases, remains unshaken. When everything else has been tried and found unavailing, these baths, with due preparation and proper management, may still be held as specific in the immense majority of instances.

"I have been taken to task by some of my reviewers for not entering more into detail relative to these remedial means; suffice it to say, that in 1822, at the hospital of St. Louis alone, at Paris, 127,752 of these baths were administered. In 1833, the number had increased to upwards 150,000 in the year. In 1834, and 1835, upwards of 180,000 were administered each year. In November, 1836, I was informed the number would be about the same, as the baths were always full; and of sixty-two patients whom I saw present themselves to the Baron Alibert, one morning, for consultation, only seven were prescribed for, exclusive of one or other of these baths as part of the treatment.

"The numbers may surprise the reader, and the surprise will be increased when he considers that these baths are erected at the other hospitals, prisons, and poor-houses throughout Paris, where they are continually taken, not only as curative of disease, but as preservative of health.

"In this country, it is true, no such opinion of the worth of vapour and fumigating baths at present exists among the members of the medical profession; yet I should imagine that the time was not far distant when their utility will be generally acknowledged; and in confirmation of this idea, I may say that I have lately superintended their erection at three of our metropolitan hospitals. These facts speak loudly for the efficacy of the remedy to which I have such frequent occasion to refer in the following pages."

TO CORRESPONDENTS.

Argus. Be that as it may, there has not been any statement given of the receipts of the fancy fair, nor is it probable that it ever will be given, unless by *legal* enquiry, instituted by the governors of the charity.

A life Governor. The particulars of the baker's account ought to be in the hands of the treasurer, we have no authority to give the names of the individuals, whom our correspondent supposes to have benefitted by the loaves and fishes.

There is no mystery about the distribution of *three five pound notes*. One was given for the "flag of truce," the other for electioneering purposes, and the third for rendering a certificate palatable to the examiners.

Otitis. The deaf and dumb shall be duly attended to. There is none so deaf as those that won't hear.

Artophago-Pharmacologist. Dr. Roderick Macleod's bread pills will be more genuine, provided they be compounded, either of the Whiting loaves, Uwin's breakfast bread, the Abernethian biscuit, or the rolls of the Golden Cross baker.

Anti-Homœopathist.—We believe that Dr. Chambers received his appointment through the mediation of his amiable and much lamented friend, Sir William Knighton. Sir Wathen Waller's opinion would be invaluable.

Bull. The veratria is rubbed on by the doctor himself every morning, and by the patient every evening. The usual fee is daily expected; but no additional charge is made for the *unction*.

X X. Aloes may be taken in this case from one to five grains in each dose, with or without capsicum.

A Westminster Elector. The cut-throat metaphor was too plebeian,—*Vox et preterea nihil*.

J. M. It is a long lane that has no turn.

Inquirer.—The largest dose of the carbonate of iron we have as yet heard of was given in the North London, in anæmial cases.

NORTH LONDON SCHOOL OF MEDICINE.—The Summer Courses of Lectures will Commence on Monday, next, the 8th of May at No. 4, Charlotte Street, Bloomsbury, in consequence of the intended Premises not being quite ready for the reception of Pupils.

For Particulars apply as above, or to the respective Lecturers.

London Medical and Surgical Journal.

cess in Practice—Inefficiency of Connections, Address, and Intrigue—Professors of Necromancy—Scientific Monsters—Professors of Laputa—The Age of Farce—Justice Shallow—Lynx-eyed Patients—Pompous Practitioners—Buff and Blustering Doctors—Medical Sir Oracles.

It is not uncommon, even in the present day, to meet with persons who despise, or affect to despise every thing like reasoning in medicine, and who hold, or affect to hold, every thing connected with the profession exceedingly cheap, except the bed-side and the operating theatre. But, let us inquire for a moment who they are who, for the most part, indulge in these sarcasms against theorising in medicine. They are generally either very young men, actuated by a strong but mistaken spirit of ratiocination, who having in an evil hour discovered, for their's is the time of life for making great discoveries, that reasoning is quite inadequate to explain satisfactorily many of the functions of the healthy body, and has more frequently led to fatal errors in practice than to the discovery of any useful remedies for diseases, have concluded, for their's is the time of life also for drawing sweeping conclusions, that theory is quite out of place in medicine, and have, accordingly, with great self-complacency, settled themselves in ten minutes into more sound philosophers than persons who have given months and years to a careful and laborious study of the subject. Or they are, on the other hand, oldish men somewhat, perhaps of the dullest; at least, not violently addicted to reasoning at any time, who having succeeded in obtaining a tolerable reputation, and in scraping together, perhaps, a tolerable commodity of money, without reasoning, have voted theory to be altogether useless to a man of the world, and continue to chuckle

with lack-lustre eye and with all the petty malignity of half-conscious imbecility over the superior straight forward understanding which they wish to flatter themselves, and to persuade others, nature has given them, instead of the splendid reasoning talents with which some luckless wights are, to their great prejudice, endowed. It is melancholy to be obliged to listen, at this time of day, to such false philosophy on the one hand, or to such wretched drivelling as this; but as they must be often listened to, so they should now and then be answered.

It cannot indeed be denied that reasoning, on the subject of physiology, is often dreadfully at fault, and that many of the processes going on in the living body are so obscure and complicated as to appear almost unintelligible. But because we cannot comprehend every thing are we, on that account, to acquiesce in total ignorance of those things which may be understood? And how can we ascertain whether any thing is unintelligible or not, unless we frequently and earnestly attempt to understand it? Every other science has advanced gradually to maturity, and it is reasonable to expect that physiology, perhaps one of the most intricate of all, should all at once become perfect, or to discard it altogether because it is not so? The most violent declaimer against medical science cannot deny that it has advanced much since its origin, and that it is still rapidly advancing; but what would now have been its condition had men always argued as he argues? Amid his common-place and hacknied sneers at medical theories in general, such a man is often remarkably brilliant in sneering at the crude notions of the ancients in these matters; but he forgets, in the meantime, that these crude notions are all we should have possessed had the people of every age been all as senseless as he. The subsequent cultivation of the study of physiology has enabled him to see the defects of the ancients; and the continued cultivation of it will probably enable the people of future ages to detect those of modern theorists, till at length the science shall arrive at perfection. The goal is not yet attained, and a great part of the fruit of our labours is perhaps as absolutely out of our reach now, when we are probably only a few feet from it, as it was when we were many miles off; but these few feet will, in all likelihood, be speedily passed over, if we do not flag in the last stage of our journey.

The man who has all his house finished except the roof is not much more defended from "the pelting of the pitiless storm" than he who has but just laid his foundation; but he is in a fairer way of becoming so. In like manner, the whole fabric of physiology may perhaps want only a few links, a few rivets, to perfect it, and to amalgamate parts at present apparently baseless, chaotic, and grotesque, into a firm, a consistent, and a beautiful whole. Besides, there is always something infinitely more exciting to an aspiring mind in the idea of prosecuting a study in which something still remains to be done than one in which every avenue to discovery and to the distinction consequent on discovery is closed, and to such a mind, therefore, the very imperfection of the science of physiology, so far from being an argument for declining the study of it, will be one of the strongest arguments for persevering in it. Enough has been already done to show that the attainment of perfection is not impossible; enough still remains to be done to inspire, in any but the most sordid mind, an ardent desire of being in some degree instrumental to the attainment of that perfection.

But it is further alleged, that theorising in medicine has less frequently led to the discovery of useful remedies than to practices absolutely pernicious. This argument can be urged only by those who are either very ignorant or very unjust. It might indeed have been expected, *a priori*, that a science not yet arrived at maturity would not have given rise to any wonderfully useful results; and we might have been content to wait till the good time should come, when the accumulated contributions of all preceding physiologists should be collected into a stupendous whole by some master-mind, who, doing for the theory of medicine, what Newton did for natural philosophy, Linnaeus for botany, Lavoisier for chemistry, and Bichat for general anatomy, should separate the wheat from the chaff, and make every thing work together for an honour and a blessing to mankind. All this might have been patiently waited for, without any fair ground of reproach against the science in question; but such prospective fruits are not all that mankind has even already derived from the study of physiology. It would not indeed be difficult to prove, that so far from no useful remedies having been suggested by theory, there are, in fact, but very few useful remedies which may not be traced to this source. "Among

the least informed people," it has been lately observed, "and in the remotest villages, there are old saws and rules relating to health, sickness, and wounds, which might be thought to come from mere experience; but they are, for the most part, on the contrary, the remains of forgotten theories, and of opinions laid down by the learned of former days."

Dr. Gregory used to remark, that it was a great mistake to imagine that old women and ignorant people in general do not theorise, but that, on the contrary, they are for the most part incorrigible theorists. This, however, is not quite the case. Such persons, left to themselves, do not theorise, but are governed in general by the most brutal superstition. When they appear to theorise, they only repeat the theories of the learned, of ages long forgotten; and a person of research may still often recognise, in the really valuable precepts of the sick-room, the tenets of the Dogmatist and the Methodist, the chemical pathologist, and the jatro-mathematician. Thus, the employment of cold and heat, in the diseases in which they are respectively useful, of animal food in some cases, and of vegetable food in others, sometimes of pure air and sometimes of the reverse; all this has, in most cases, originated in theory; and it is to this that we owe the introduction into medicine of sialagogues, errhines, demulcents, emetics, purgatives, blisters, diaphoretics, diuretics, and almost every other class of useful medicines; to take diuretics as an example. Had it not been for the notion entertained by Hippocrates, that dropsies arose from a preternaturally attenuated state of the blood, and that the natural office of the kidneys was to thicken the blood by drawing off its thinner particles, it is impossible to say how long it might have been ere we stumbled on the use of diuretic medicines, on which we now place our chief reliance in dropsy, and a very similar remark might be made with respect to all the other classes of medicines just mentioned, as well as to innumerable others. We forget all these things, or, what is more probable, we have never known them, when we join in the senseless outcry against the utility of theorising in medicine. When applying hartshorn or other pungent substances to the nostrils, in hysteria, epilepsy, or syncope, or when introducing a pessary to support a prolapsed womb, few, perhaps, are aware that these practices owe their origin to a wild theory, propagated by Hippocrates

and Plato, that the womb was a kind of living animal, of a very unsettled disposition, and as often as it found itself deficient in heat and moisture, in its usual quarters it was capable of wandering about in search of more. In these wanderings it was said usually to ascend, for they made very light of its ligaments, touching sometimes at the liver, sometimes at the stomach, sometimes at the heart, sometimes even at the fauces, to the great discomforture of these quietly disposed organs, and the consequent production of a fit of hysteria. On other occasions, however, it was described as descending, particularly when the deficiency of head and moisture seemed to arise from a too sparing gratification of its natural desires, and in these circumstances it sometimes peeped forth from its natural recesses in order to inquire personally into the state of affairs, and to ascertain the reason why it had been so long unsatisfied. "If you want your work done," says the proverb, "go, if not, send;" and in conformity with this precept, the womb was described as sometimes presenting itself without ceremony before the astonished multitude, and thus constituting a prolapse of that organ. Now the said womb, as an animal, was of course susceptible of pleasure from agreeable odours, and of annoyance from the reverse; and, accordingly, when it ascended they attempted to frighten it from above by the application to the nostrils of assafoetida, or any other offensive substance, and at the same time, to entice it from below by introducing aromatics into the genital organs. In like manner when it descended it was to be disgusted from below as well as attracted from above, by the application of fetid substances to the vagina, and aromatic substances to the nostrils. The application of offensive substances to the nostrils soon led to that of any other substances equally pungent, and the advantages derived in hysteria from remedies of this kind soon led to their adoption in epilepsy, syncope, and other disorders, while the pessaries of antiquity, as employed in prolapse of the womb, and which originally consisted of fetid substances, soon gave way to machines of wood and ivory; but still it is to theory, and that too of the most unpromising character, that we owe the introduction into practice of both these classes of remedies. I might likewise add galvanism, acupuncture, and numerous others, as further examples of excellent remedies,

for the introduction of which we are indebted to theory; but sufficient, it is presumed, has been said already to refute the random assertion that practical medicine owes no useful remedies to the prosecution of theory, and to prove that the common-place cant of the empirics, "non post rationem medicinam, esse quasitam," is as false as it is hacknied and tiresome.

With respect to theory having given rise to practices absolutely pernicious, it cannot indeed be denied that such has sometimes been the case; but if a little theory has sometimes done harm, a little more has commonly corrected it. The cruel practice, for instance, of denying cool air to patients parched with fever, took its rise from the pernicious doctrines of the chemical pathologists, who held that the process by which a fever is expelled is analogous to fermentation, and is therefore to be promoted by heat. But, on the other hand, the practice of freely admitting air was the consequence of the doctrine, that the essence of fever was excess of heat; for which cold was the best as well as the most direct remedy. Again, the barbarous practice of inculcating abstinence from drink in fever and in dropsy took its rise from the doctrine, that in the former it added fuel to the flame, as water sprinkled on the fire only serves to make it burn more furiously, and that in the latter it still further diluted the blood, which was too much diluted already. But then, the opposite practice of allowing the free use of liquids in both originated in the notion that they favoured the action of diaphoretic medicines in fever, and of diuretic medicines in dropsy, from the free operation of which the cure of those diseases was principally to be hoped for. But it is superfluous to multiply instances to prove that if theorising sometimes does a little temporary mischief it always sooner or later abundantly repairs it, and I shall presently have occasion to show that if erroneous practices have sometimes resulted from theory, practices much more erroneous have resulted from the neglect of it, and from the idle superstition with which this neglect is always accompanied. From errors arising from the latter source we can have no reasonable hope of deliverance; but if theory occasionally brings a bane, it brings likewise more or less speedily its own antidote: and while in these instances the benefits derived from it are at least equal to the injury, its advantages in others are without alloy,

and so numerous and considerable as to furnish us with a ready and decisive answer to the few and meagre arguments which can be brought forward on the opposite side of the question.

But we have still to defend ourselves from the leaden attacks, not of the mistaken philosopher, but of the Goodman Dull, the downright matter-of-fact man, the stupid, indolent, and worldly-minded creature, who, provided he has "succeeded" in the world, in his grovelling acceptance of the term, cares no more than Mrs. Shandy did whether that world goes round or stands still. Such men as these have succeeded in the world as they call it, but it was at a time when the world and the medical profession were not what they now are, and still less what they every day more and more promise to become. The time has been when the doctor was looked upon by his bigotted patients as a being who had become, either by study or inspiration, something almost supernatural. But these were times in which doctors were scarce, and every avenue to medical information being closed against the "prophanum vulgus," the elect few had a monopoly, like the monks of the dark ages, if not of learning, at least of the credit of it, and certainly of the loaves and the fishes which were intended for its reward. Doctors are not now what they once were, "*rari nantes in gurgite vasto*;" but rather like the stars of heaven for multitude; and the persons by whom they live are considerably more behind the scenes. The late rapid march of improvement, a march which becomes more and more rapid every day, has already wonderfully contracted, and promises shortly to obliterate entirely that great gulf which was formerly fixed between the philosopher *ex professor* and the *οἱ πολλοί*. In the first place, the greater diffusion of education which renders every body capable of reading, and then the shoals of publications on every branch of science and literature, and on medicine perhaps more than any other, which emanate from the press every quarter, every month, every week, and almost every day; and many of which come in such a "questionable shape," that they are read by almost every body who can read; and again, the number of scientific and literary societies in almost every town, in which subjects, till lately clouded in pomp and mystery, are familiarly discussed by all classes of people; nay, the improved tenour of the most

every day kind of conversation, in which it is no longer considered indecorous for the *scavan* to laugh with the plebeian, nor presumptuous for the plebeian to dispute with the *scavan*; all this has already done much towards establishing every man, and in particular every medical man, on his proper level of reputation with respect to his attainments, and will, ere long, it may confidently be expected, entirely sink every claim to notice of all who do not thoroughly deserve it. But not only must the medical men of the present day labour to gain knowledge, in proportion as their patients become better judges of their standing in this respect, but they must labour hard in proportion as the knowledge now to be gained is more deep, more extensive, and more mutable than before. In former times, medical authors were comparatively few; facts and opinions were slowly collected, and doctrines once established required the lapse of ages to undermine and subvert them. At present almost every medical man thinks and writes, as well as reads; the discoveries and notions of every body are diffused, with the rapidity of lightning, and by innumerable channels, through every quarter of the civilised globe, and revolutions in medicine are now so frequent that, when an old student returns to his college ten years after having left it, if he have not in the meantime continually kept up his stock in trade, he hears nothing in reply to his sagest remarks, but Moliere's sweeping answer, "*Nous avons changé tout cela*," till at length he can hardly believe that he really belongs to a profession, of which he had previously flattered himself he was no inconsiderable member.

Let not a young man trust for success, then, to the same quiescent modicum of scientific information, which peradventure helped forward his grandfather or his father to riches and honour. Let him not trust to connexions, to intrigue, to address, to any thing but a thoroughly manly knowledge of his profession, and that not of a description in which perhaps any old nurse will excel him after all. Let it not be practical only, but theoretical also. The big wig and the gold-headed cane have long been out. It is long since it was thought necessary (as remarked by Dr. Black), in order to appear a man of deep learning, to resemble a professor of necromancy, or a lethargic philosopher of Laputa, or a sceptic monster; and the days are fast approaching, when neither a severe and

pompous carriage, on the one hand, nor a bluff and blustering demeanour, on the other, will deceive mankind into the belief, either that a medical man possesses science, or that he despises it. In every thing, scientific as well as political, the age of farce is gone,—the mist of delusion is fading away. In every town and village, where there is any thing worth competing for, a medical man will meet with worthy competitors, and with patients who can judge of his pretensions. The latter will be among the first to see "the bottom of Justice Shallow." If they read nothing else, each will read all he can find about his own case. He will question his doctor upon all the various opinions respecting it; and upon all the arguments for and against those opinions; and, in short, upon every subject connected with it, directly or indirectly. The doctor, if he be a blockhead, will soon betray it; for the eye of the lynx is dull compared with that of an anxious patient, when scrutinizing his medical attendant; and the latter, if incompetent, will be unable to parry, either by artifice or bravado, the home-thrusts he will receive. His quivering lip will refuse any longer to furnish the ready smile. He will be convicted of ignorance and presumption; and will share the just reward of the ignorant and presumptuous—contempt and disgrace!

But it is not his patients alone who will be his judges. The subjects embraced by physiology come home to every man's "business and bosom;" and in every company the medical man is the "Sir Oracle," to whom all appeals on such subjects are made. What, if he cannot meet these appeals? What, if in the first company he enters in the town in which he has set up his brass-plate, he should meet with a dozen persons better informed than himself? An ignorant medical man of the present day (in addition to all his practical high crimes and misdemeanours) must necessarily be a despicable shuffler. No man can know every thing; but he who knows much can afford openly to confess when he is at a loss. An ignorant professional man, on the contrary, cannot afford to be honest. He must equivocate, and hedge, and lie at every turn; and be obliged to take, perhaps during a long life, ten times the trouble in order to appear well informed, which it would have cost him during a few months when a student, really to become so. But all will not do. He will soon see that he is known and despised, and will soon feel himself neglected and abandoned!

LECTURES ON SURGERY,

BY

JOHN HUNTER, F.R.S.

ON THE VITAL PRINCIPLE.

Difficulty of comprehending this Principle—Complicated in its Effects, but simple in its Essence—Not the Result of any perceptible Arrangement of Matter, giving rise to a Principle of Preservation—This the simplest Idea of Life—Illustrations—Erroneous Comparison of Life to mechanical Powers—Action not an essential Property of Life—Life without Action—Vitality of an Egg—Experiments—But Action promotes the Continuance of Life—Apparent Exceptions to the conservative Power of Life—Peculiar Form of Putrefaction in certain Bodies—Death of a Part of the Body previously to general Death—Physiology of the Blood.

Animal matter is endowed with a principle called life in common language. This principle is, perhaps, comprehended with more difficulty than any other in nature, which arises from its being more complicated in its effects than any other; and it is therefore no wonder that it is the least understood. But although life may appear very compounded in its effects in a complicated animal like man, it is as simple in him as in the most simple animal, and is reducible to one single property in every animal.

I have observed that animal matter exists in two states; in one it is endowed with the living principle, in the other it is deprived of it. From this it appears that the principle called life cannot arise from the peculiar modification of matter, because the same modification exists when this principle is no more. The matter separated from life appears at all times to be the same, as far as our senses and experiments carry us. If life arose out of this peculiar modification, it would not be destroyed until the modification was destroyed, either by spontaneous changes, as fermentation, or by some chemical processes; and were it destroyed by the last, it might sometimes be restored again by another process. Life, then, appears to be something superadded to this peculiar modification of matter; or this modification of matter is so arranged

that the principle of life arises out of the arrangement, and this peculiar disposition of parts may be destroyed, and still the modification, from which it is called animal matter, remain the same. If the latter be the true explanation, this arrangement of parts, on which life should depend, would not be that position of parts necessary to the formation of a whole part or organ, for that is probably a mechanical, or at least organical, arrangement, but just a peculiar arrangement of the most simple particles, giving rise to a principle of preservation; so that matter so arranged could not undergo any destructive change till this arrangement would be destroyed, which is death. This simple principle of life can with difficulty be comprehended; but to show that matter may take on new properties without being altered in itself as to its kind, it may be not improper to illustrate this idea by such changes in other matter. Perhaps magnetism affords us the best illustration of this point. Iron appears at all times the same, whether endowed with magnetism or not; and magnetism does not seem to depend on the formation of any of its parts. A bar of iron without magnetism may be considered like animal matter without life; but set it upright and it acquires a new property, of attraction and repulsion, at its different ends. Now the question arises, Is this any substance added; or is it a certain change which takes place in the arrangement of the particles of iron giving it this property? If we take a piece of glass, it is transparent; we break it into a thousand pieces and it becomes white. Whiteness is not a new matter added to it, but a property arising from its being composed of a number of small pieces.

It was not sufficient that animal matter should be endowed with vitality, the principle of preservation, it was necessary that it should have action or motion within itself. This does not necessarily arise out of the arrangement of parts for preservation; on the other hand, the arrangement for preservation, which is life, becomes the principle of action, not the power of action, for the power of action is a different one. The power of action must arise from a particular position of living parts, for before action can take place the matter must be arranged with this view. This is generally effected by the union of two or more living parts, so united as to allow of motion on each other, which the principle of action is capable of effecting when so disposed. A

number of these simple acting parts, united, form a muscular fibre; when a number of these fibres are put together they form a muscle, which, joined with other kinds of animal matter, as tendon, ligament, composes what may be called an organ. Thus, too, by the arrangement of the living particles, the other organs of the body are formed, their various dispositions and actions depending on the nature of the arrangement, for action is not confined to muscle, the nerves also have action arising from the arrangement of their living particles.

The principle of life has been compared to the spring of a watch, or the moving powers of other machinery; but its mode of existence is entirely different. In a machine the power is only the cause of the first action or movement, and thereby becomes the remote cause of the second, third, &c.; but this is not the case with an animal; animal matter has a principle of action in every part, independent of the others, and whenever the action of one part (which is always the effect of the living principle) becomes the cause of action in another, it is by stimulating the living principle of that other part, the action in the second part being as much the effect of the living principle of that part as the action of the first was of the living principle in it. The living principle, then, is the immediate cause of action in every part; it is therefore essential to every part, and is as much the property of it as gravity is of every particle of matter composing the whole. Every individual particle of the animal matter, then, is possessed of life, and the least imaginable part which we can separate is as much alive as the whole.

The first, and most simple idea of life, I have observed, is its being the principle of self-preservation, preventing matter from falling into dissolution,—for dissolution immediately takes place when matter is deprived of it; and the second is its being the principle of action. These are two very different properties, though arising from the same principle, the first being capable of existing independently of the second; for it may be observed, that it is not necessary for the preservation of animal matter that there should be action in all parts, for many parts of an animal appear to have little action, yet they are as much endued with life as the more active parts; such, for instance, as tendons, elastic ligaments, &c.

A fresh egg is a body which, it must

be allowed, has no vital action; yet an egg is as much alive as an animal, which I shall endeavour to illustrate by observation and experiment. I was led to this opinion in the year 1757, when I was making drawings of the growth of the chick in the process of incubation. I then observed, that whenever an egg was hatched, the yolk, which is not diminished in the term of incubation, remains sweet to the last, and that part of the albumen which was not employed in the growth of the chick was perfectly sweet some days before the hatching, though both had been kept at a temperature of 103 degrees in a hen's nest for three weeks. But if the egg did not hatch, I observed that it became putrid nearly in the same time that other dead animal matter does.

To determine how far eggs would stand other tests of the presence of the living principle, I made the following experiments:—I put an egg into a freezing mixture about zero, and froze it, and then allowed it to thaw. From this process I conceived that the preserving power of the egg must be lost, which proved the case. I then put the egg into a freezing mixture at 15 degrees, and with it a new-laid one, to make the comparison on that which I should call alive, and the difference in the time of freezing was seven minutes and a half, the second one taking so much longer to freeze. 2nd. I put a new-laid egg into a cold between 17 and 15 degrees; it took about half an hour to freeze: when thawed I put it into an atmosphere only at 25 degrees; it froze in half the time, which it should not have done, nor even in half an hour, if it had not been killed by the first experiment, for the atmosphere now was not so cold as in the first experiment by nine degrees. These experiments show that the egg, when living, has a power of resisting, cold, which, when killed by freezing, it loses.

To determine the comparative heat of a living and dead egg, and to determine whether the former be subject to the same laws with the more imperfect animals, I made the following experiment.

I took a fresh egg, and one which had been frozen, and put them into a cold mixture at 15 degrees. The thawed one soon came down to 32 degrees, began to swell and congeal: the fresh one sunk to 29½ degrees, as happens to living animals, and froze in twenty-five minutes after the dead one. Another reason for supposing it dead was, that before free-

ing took place it rose to 32 degrees, as other fluids do which are brought below their freezing point.

From these observations and experiments, it must appear that a fresh egg has a power of resisting heat, cold, and putrefaction; and similar results are come to by similar experiments on some of the more imperfect animals, which we shall have occasion to notice hereafter.

It would appear, then, that life is not *action*, but it is continued or supported by *action* when it takes place. Action creates a necessity of support, and furnishes it. It is not necessary that *action* should continue in all parts; in some it is only necessary that the principle and power of action should be continued, but in others it is necessary that *action* should take place even for the preservation of the principle of Action. Action is necessary for the various purposes for which the animal is intended, and if one species of action takes place, it brings the whole into action, as all the parts and actions of an animal body are dependent upon one another. If the heart acts, the lungs must fulfil their part; the stomach must digest, the other parts subservient to this organ must be put in motion, and the secretory organs, nerves, and voluntary muscles. The whole is thus put in motion to produce some ultimate effect, which appears to be the propagation of the species, for preservation (of the individual) cannot be called the ultimate effect.

I have asserted that life simply is the principle of preservation in the animal preserving it from putrefaction; but there is a curious circumstance attending life which would appear to be contradictory to itself. Life is the preserver of the body from putrefaction, and when life is gone putrefaction speedily begins. But this is not uniform; it is sooner in some cases than in others; therefore there must be some other cause than the simple deprivation of life to account for this difference of time. In the most striking instances of rapid putrefaction after death, it does not appear to arise from the process of putrefaction having gone to some length before total or real death took place, for in those who die of putrid fever the smell becomes less offensive before death, and when life is gone they do not go into putrefaction as soon as might have been expected, and not nearly so fast as many who had not the least tendency this way before death. The tendency to putrefaction in those whilst living would appear to be part of the disease, but does not be-

come putrefaction, and on dying they appear to lose that tendency, and to become like other bodies. However, it is disputed whether, in putrid fever, there is really any putrid matter formed.

But there is a process or an action in life which predisposes the body to many diseases, and which becomes the remote cause of them; and there is an action in life which disposes the body to a species of putrefaction (or decomposition) when dead, and very probably death is the effect of this action in these cases. In these cases the body immediately after death becomes emphysematous; this emphysema, though it does not occur during life, would yet appear to be an effect of life, for it depends on disease as the body is dying. It is not genuine putrefaction; for, when the process is ended, the body keeps nearly as long as if no such process had taken place. It occurs immediately after death, or perhaps in the act of dying. The process itself seems to continue when the body is warm; after a time it stops, and the body remains stationary, until it sets out, as it were, for a second time to become putrid. What diseases this is to be classed with I do not know. To ascertain the causes of it with precision, it would be necessary to know the persons when alive, the disease of which they died, and the time when the putrefaction occurred after death. I have myself seen several very remarkable instances of its occurrence. The first was that of a young lady about four months gone with child, who, in March or April, about two or three in the afternoon, was suddenly taken ill with a fit, of which she shortly died. She was opened the next morning at seven o'clock, when the body was found swelled with air extravasated in the cellular membrane; the mesentery, intestines, liver, and heart were loaded with air, the blood worked out of the larger vessels mixed with air, and the body had become very offensive.

Another case of the kind occurred at St. George's Hospital, in a man who had an encrusted tumour in the upper belly of the right rectus muscle, which contained a fluid: it was opened on Friday, and on the Monday following, in the evening, he became ill, and died at one o'clock. He was opened seventeen hours after death, and was found emphysematous, just as in the former case.

This appears to be similar to what is commonly termed sphacelus, being a species of mortification occurring before death, or in the act of dying.

That the mode of dying assists the process of putrefaction is evident in common mortification, which will be noticed when on that subject, and I may illustrate it further by relating what took place in a case of operation for aneurism.

A man at St. George's Hospital had the operation for popliteal aneurism performed. The artery was tied just where it passes through the tendon of the triceps muscle. The case went on well till the sixth day when ulceration took place in some part of the artery which was not united considerable bleeding took place, and recurred several times afterwards, by which so much blood was lost as to become in the end the cause of death. Immediately after the first bleeding, I observed the foot and leg of the deceased side to become cold as high as the middle of the calf, while it was warm about the knee, ham, and upper part of the leg. The lower part of this leg ever after remained cold, and did not in the least change in appearance, from which I conjectured that it was *dead not mortified* (for there is a material difference.) I suspected it was *dead* as in common death. He became weaker and weaker every day, and died about four days after. Before he died, the upper parts of the leg, which had retained life a little longer, were mortified, that is, they showed evident signs of such a change taking place; a vesication formed, discharging a bloody serum, and they became darker, as if blood was diffused in the cellular membrane, and œdematus, or rather emphysematus. A very short time after death these parts became putrid, while the lower part of the leg and foot remained unaltered as in common death. Here was a part which just died for want of circulation, therefore no action took place in that part; but above, where there was action, a very different change took place, producing a tendency to putrefaction after total death had taken place. The part which died naturally without any action did not become putrid, while the part in which that peculiar action took place became putrid directly, though it died later. I took off the two feet to see which of them would become putrid first; for some time it was difficult to perceive any difference, but about sixteen days after, the foot on the sound side began to turn green, and went on to putrify much faster than the other.

The whole of this part of the case is extremely curious. First, that part of the leg which retained life longest became

putrid immediately after death, because during life it took on actions which were productive of putrefaction. The foot of the diseased side, which died early, was not allowed time to take on any actions while living, excepting perhaps that resulting from the stimulus of death, and did not become putrid so soon as the foot on the sound side, which may be said to have died a natural death, and which died later. This I think may be accounted for by supposing that the latter, from surviving some time longer, took on some of those actions which gave the tendency to putrefaction. It may be necessary to explain what I mean by the stimulus of death. Death itself produces an action in all the muscular parts when there is nothing to prevent it. If a man's head be cut off he becomes stiff; he is not stiff while there is real life: for there is a difference between visible life and real life. A part may be living though not in action; but whenever death takes place it excites an action in every part that is muscular: they contract, and this is the action of death. To cease breathing is not the action of death, though certainly it is the first step towards it, and gives rise to the other. The action of real death is that which takes place in the stiffening of the body, and till then it is not dead (except when killed in a peculiar manner—killed universally before the stimulus of death can be given,—and then it remains lax).

I suppose, then, that this foot, which died first from the loss of blood, became stiff; that is, took on action resulting from the stimulus of death, all the muscular parts contracting;—that in the other foot the stimulus of death was in some measure lost from the longer continuance of the diseased state, and the consequent action was less strong. What would be the consequence of this? I take a man in perfect health, and cut off both his legs; to one I give a stroke of electricity sufficient to kill the part before it contracts, and no contraction takes place; the other I leave to itself and let the stimulus of death produce contraction; this latter will not become putrid so rapidly as the former.

Physiology of the blood.—What I have had hitherto principally in view has been the solid animal matter, its formation, and its arrangement by which it is endued with life, composing, as it were, the whole visible body. The fluid part of the compound now remains to be noticed.

Blood is the material by which the whole body is formed and by which it

is supported. It is fluid that it may be capable of moving to the very minutest part of the solid with ease, and may with less difficulty be divided for the increase and repairs of the different parts of the machine; easy of division and separation, to form various secretions, and also to bring back what was superabundant, and to carry off the parts which were useless.

This part of the body has been considered as a passive, inanimate, moving fluid, found every where in the body, deriving motion from the heart for the various purposes of the whole, then returning to the heart to be again circulated. Those who have formed this idea of the blood have no adequate notion of the manner in which it is capable of performing those great uses above mentioned. Some in considering this fluid; have been in a great measure satisfied with examining the spontaneous changes which it undergoes out of the body. This might have led them to draw some natural conclusions, since all natural phenomena are facts, and teach enough of a thing to enable us to draw sound conclusions. Others have attended to the chemical analysis, which teaches nothing with respect to its use in the living body; for blood gives no analysis excepting that of common animal matter. Some inquirers have laid great stress on its appearance when viewed with a microscope, as if forms of parts would explain first principles, which they cannot do unless in operations that are mechanical. This inquiry could be carried no further than to investigate such parts of the blood as have form and opacity, if there are such, and that which appears to have both is called red blood; in a great number of animals, therefore, the knowledge of the operations of the blood in the animal body rests nearly in the same state that it did some centuries ago. The two last points of investigation, namely, the chemical analysis of the blood and the form of the blood globules, though very proper to be made by physiologists, have hitherto explained nothing in the animal economy.

Before I explain my opinion of the blood, it may be not improper first to state some facts from which I draw my conclusions.

I have endeavoured to show that animal matter differs from common matter in many circumstances; that animal matter has a principle peculiar to itself, which I call *life*, and this life is the second step or process of animal matter. Animalization is the first; vivification the

second. To prove this, I observed that an animal is increased and supported by many substances which previously had not the properties of animal matter, and of course not the principle called animal life; I observed, too, that it was also supported by substances which were of animal origin, but which had not then the living principle: in other words, an animal can be supported on dead vegetable or animal matter. In the next place it was remarked that these substances, before they can increase or support the animal, must all be converted into animal matter; and lastly, that the substances must be so prepared, or animalized, as to become part of the body, and of course to be endued with the living principle.

It is now necessary to trace these changes in the food till it becomes part of our solids, and observe as we go along when it is most probable that life begins.

Blood is not simply fluid animal matter, it is animal matter particularly arranged, for it differs in every respect from fluid animal matter produced by art. The first change that takes place with vegetable matter before it is rendered blood is its conversion into animal matter. This change I call animalization. With animal matter it might be supposed that no change was necessary to produce animalization; but we find the change, whatever it may be, the same in both; and the process in both is probably similar, for the produce from the digestion of animal matter is as different from common animal matter as anything can be; were it not so, animal substances rendered fluid by chemical operations, as jellies, &c., would answer the same purpose as blood. But the necessity for a total and similar change in both is evident, for out of this change life is to arise, digestion being the first step towards vivification. It may be supposed that the first step in the digestion of vegetables is that of animalizing them, and that they go through the next of chylicification with animal matter; but this we cannot allow, for it would be supposing two different actions going on in the stomach at the same time, which I should very much doubt.

The second process of vivification, must take place somewhere before the blood becomes an active part of the machine. We shall first premise that animalization may take place without vivification—(how far this is the case is not easily determined,)—however, we may say with certainty that vivification cannot be prior to animalization. Let us first trace animalization.

ANEURISM OF THE ARTERIA
INNOMINATA,
AND
ORIGIN OF THE SUBCLAVIAN
ARTERY,
TREATED BY LIGATURE OF THE COMMON
CAROTID ARTERY.

To the Editor of THE LANCET.

SIR,—I send you for publication in your excellent periodical, the particulars of a case of aneurism of the arteria innominata, and origin of the subclavian artery, treated by ligature of the common carotid artery, in accordance with the principle first advocated by Brasdor, and lately revived by that enlightened and able surgeon, Mr. Wardrop.

The interest felt by the profession in the cases of aneurism treated by ligature of the vessel on the distal side of the tumour, as first published in your journal, and subsequently in Mr. Wardrop's work on aneurism, coupled with the fact, that this is perhaps but the second or third case of aneurism of the innominata in which any attempt at cure by operation has been made, will be the best apology I can offer for the length of this communication, and for what may appear to some to be an unnecessary and tedious detail of the symptoms as they occurred daily after the operation. I have the honour to be, Sir, your obedient servant,

S. W. FEARN.

Derby, Oct. 1, 1836.

CASE.—Aug. 22nd. Mary Scattergood, æt. 28, states that her present illness has existed five months, and that it commenced with a *violent fit of coughing*, one night when she was going to bed. Soon after this she experienced a throbbing swelling above the sternum, which, for four or five weeks gave her a good deal of pain. She was bled several times by her medical attendants, Mr. Tomlinson and Mr. Lowe, with relief from the pain in the tumour, and, shortly afterwards, was admitted as an in-patient of the *Derby Infirmary*, under the care of Dr. Bent. I examined the case, whilst in hospital, with Dr. Bent and the other medical officers, and at that time made the following observations: There was a rounded, pulsating tumour, immediately above the sternum, bounded,

laterally, by the trachea and the tracheal margin of the sterno-cleido-mostoideus, which was evidently making considerable pressure upon the trachea, near its bifurcation, as evidenced by loud wheezing, frequent cough, as general difficulty of breathing. Loud *bruit de soufflet* was heard in the supra-clavicular space, and a less distinct bruit along the course of the right common carotid. The bruit in subclavian artery was rendered more loud by stopping the transit of blood through the carotid, and when the circulation through the subclavian was arrested, the bruit in the carotid ceased. The tumour itself emitted sounds similar to, and synchronous with, those of the heart. The heart's sounds were natural, and there was no râle in the lungs. The pulse in the right wrist was very indistinct; that in the left was natural as to strength and frequency.

The prevailing opinion at this examination appeared to be, that the disease was an *aneurism of the arteria innominata*, but the surgeon to whose care she was subsequently transferred and one of his colleagues, considered that it was an aneurism of the arch of the aorta, and, of course, that any operation for its cure was quite out of the question.

Having remained in the Infirmary several weeks, she was discharged at her own request.

22. Her difficulty of breathing and cough had of late increased very much, and the acetate of morphia had failed to procure her rest at night. The dyspnoea was aggravated by the slightest exertion, and the wheezing was rendered much more loud.

After her discharge I offered to perform what appeared to me to be the requisite operation, to which proposal she very readily assented, as she had a conviction that nothing short of an operation could save her life.

27. The patient came yesterday from Burton in a cart. She passed a better night than usual, and I have this morning made a careful examination of her condition. Her cough is troublesome, and the wheezing very loud; pulse almost imperceptible in the right wrist; in the left it is natural, and gives seventy-two beats in the minute. She is obliged to lie with her head a good deal raised. The tumour is very distinct, and throbbing above the sternum, in the situation first noted, and also in the space between the sternal and clavicular attachment of the sterno-mastoid muscle. *Bruit de soufflet*

loud in the supra-clavicular region, and still increased by stopping the circulation in the carotid; there is, however, no bruit audible along the course of the carotid. I made pressure for some time upon the carotid, so as to stop the circulation through it, and was pleased to find that her breathing became, in a marked degree, more free and less embarrassed. A similar experiment upon the subclavian did not affect the state of her breathing. The respiratory murmur is natural over the whole chest, as also are the sounds of the heart.

29. I have this morning visited the patient, with Dr. Bent and Mr. Wright, and again carefully examined the tumour and the vessels proceeding from it. We found her suffering very much from the difficulty of breathing, and unable to remain for any length of time in the recumbent position. The experiment of stopping the circulation through the carotid and subclavian was repeated, and the result, so far as the carotid was concerned, was quite in accordance with what happened at the last examination. Each time when the carotid was compressed, the breathing became more tranquil, and when the pressure was removed the dyspnoea instantly returned. A similar compression of the subclavian artery increased the difficulty of breathing, but when the subclavian and carotid arteries were compressed at the same time, the relief to the breathing was much the same as if the carotid only had been obstructed.

It was not difficult, from this and the previous examinations, to determine which vessel to select for the application of a ligature. The circumstance of the circulation in the subclavian artery being already considerably obstructed, and its entire obstruction adding to the distressing symptoms, taken with the further circumstance that pressure on the carotid was followed by a relief from the dyspnoea, seemed clearly to indicate, that in any operation for the cure of the disease, a preference must be given to ligature of the carotid. And here I cannot help remarking the analogy in one respect between this case and the case in which Mr. Wardrop placed a ligature upon the subclavian artery for an aneurism of the innominata. In his case a preference was given to operating upon the subclavian, from its appearing that the circulation in the carotid had almost ceased, and in my patient I selected the carotid, because (with other reasons) the

circulation in the subclavian is considerably arrested.*

Operation.—30th. I this day proceeded to the performance of the operation, in the presence of about twenty medical gentlemen, amongst whom were Dr. Bent, Mr. Evans (Belper,) Mr. Wright, Mr. Fox, &c. The patient was placed upon a table, and it was found necessary to keep her in nearly an upright position, owing to the difficulty of breathing, and the cough being so much increased if she attempted to lie down. An incision, about three inches in length, was made, commencing an inch below the angle of the jaw, and extending downwards along the inner border of the sterno-cleido mastoideus. A small artery, which gave no trouble, was divided in this first step of the operation. The cervical fascia was then cut through, and by a little dissection, the sheath of the vessels, with some twigs of the descendens noni, and the omo-hyoideus, were brought into view. After some trouble, owing to the depth of the vessels, from the head being inclined forwards, I opened the sheath above the omo-hyoideus, but was unable to pass a ligature beneath the vessel. I therefore at once divided the belly of the omo-hyoid, and thus exposed much more freely the vessels. An armed aneurismal needle was then passed beneath the carotid, from within outwards, (contrary to the usual directions in such cases,) care being taken not to injure the vein, or to include the par vagum, and, after waiting a short time, the ligature was firmly tied.

Scarcely an ounce of blood was lost, but the different steps of the operation were much impeded by the frequent cough and the sense of suffocation, which considerably distended the veins, and by the necessity of keeping the patient almost constantly in an upright position. The artery was large, and its coats ap-

* "When in a case where either the carotid or subclavian is already obliterated by a spontaneous process of cure, then am I strongly impressed with the propriety of tying the vessel which remains open, all other circumstances being favourable. Of course no such operation would be advisable when there was any reasonable prospect of the spontaneous inactive process advancing; but if, notwithstanding the general treatment adopted, the tumours were decidedly increased, I would not hesitate to tie the open vessel."—Wardrop on Aneurism, &c. p. 83.

peared to be a good deal thickened. The sheath also appeared to be more than usually adherent to the vessels. But one ligature was employed, and the wound being dressed, she was put to bed. She complained a good deal of pain in the right ear immediately after the operation.

Progress.—At three o'clock, an hour after the operation, she was breathing tranquilly, and sat up in bed, and smoked some tobacco. Her pulse was 86; by five o'clock it had risen to 96; and at eight o'clock it was 106. Her breathing from the time of the operation had at intervals been much oppressed, and she had had many violent fits of coughing. The dyspnoea was now (eight P.M.) very distressing, and I accordingly bled her to ten ounces, and administered forty drops of laudanum. Her breathing seemed a little relieved after the bleeding, and in a short time she was able to lie down. The pulse rose to 120.

31. One A.M. The patient is now breathing quietly, and has scarcely coughed at all for the last two hours; pulse 100. The pain in the right ear, of which she complained directly after the operation, has continued, but is now rather better.

Eight A.M. Has passed a comfortable night, having slept at intervals a little. She scarcely coughed at all from eleven o'clock last night until seven this morning. There seems now, however, to be a considerable accumulation of mucus in the trachea, and she has been coughing violently for the last hour. Bowels costive. Let her take an ounce and a half of the compound decoction of aloes immediately.

Noon. The cough continued until eleven o'clock. The left side of the face is now flushed and hot, and looks plump and slightly livid; the right side has a shrank appearance, is pale and cold; the pain in the ear has entirely subsided. To repeat the decoction of aloes, and to have two dozen of leeches applied to the upper part of the chest.

Six P.M. The leeches have bled freely, with evident relief to the breathing. Bowels not open. To have a common purging draught.

Sept. 1st., half-past one A.M. Bowels open twice, freely; she has, however, great difficulty of breathing, and makes a loud wheezing noise. *Hæbat hæust. c. ether. sulph. ʒss., et tr. opii. gtt. xxx.*

Eight A.M. Soon after the last visit her breathing became better, and she has passed a very good night; she has slept

for two or three hours, and expresses herself this morning as a good deal relieved. Bowels open; pulse 120; the pulse in the right wrist about the same as before the operation,—if any thing, rather more feeble. She says that she cannot now feel the "beating of the lump," which she could distinctly before the operation, but she feels a stoppage at the lower part of the windpipe. Skin cool, face not flushed. She passed the remainder of the day comfortably, sleeping for two or three hours at a time, and she has been less troubled with the cough and dyspnoea.

2. Eight A.M. Has slept but little; her cough has teased her most in the night, though she says her breathing is more free. Has expectorated a large quantity of frothy mucus, and has been repeatedly so sick as to vomit; pulse 120.

Five P.M. The expectoration has, during the whole day, been very profuse, and attended with violent fits of coughing. There is the most marked mucus rattle in the trachea and the larger bronchial tubes. The bruit de soufflet is heard above and below the clavicle, as before the operation, and the pulse in the right wrist has become much more distinct. The sickness has abated; pulse 135. *Appl. Hirudines xij. sterno, et sumat postea hæust. c. ether. sulph. ʒss., et tr. opii. gtt. xxxv.*

Dressed the wound, which appears to have healed by the first intention.

Half-past eleven P.M. Has taken two doses of the ether and laudanum, and appears now more composed. There is less rattle, and the violence of the cough has a good deal abated.

3. Nine A.M. Has slept, at intervals, for several hours, and says that her breathing this morning is more free. There is still, however, a good deal of mucus rattle, and the pulse is 140, and weak. Her strength seems good. To take beef-tea, and to continue the ether and laudanum at intervals of four hours.

Eleven P.M. Has been much more comfortable during the day, though the frothy accumulation continues. Bowels freely open. Continue the ether and the tincture of opium.

4. Has had a good night, and says her breathing is much better than it was before the operation. Thinks the tumour is less; it feels perhaps a little more solid, but the pulsation in it remains about the same.

5. Has been up during an hour, whilst her bed was made; feels much better;

slept six hours during the night; wound appears to be quite healed, excepting at the ligature; pulse 106.

7. A good night, and this morning she is as well as usual; pulse 100; no fever. Pergat.

9. Continues to improve; has had an excellent night, and says she has never, since the commencement of her illness, felt the beating of the tumour so little as she does now; pulse 96. If the circulation through the subclavian be stopped, the breathing becomes shorter and more difficult, and if the pressure be continued for some time, the embarrassment to the breathing is very distressing. Even slight exertion adds to the dyspnoea, but the cough and expectation are now very trifling. The tumour is considerably lessened, and its pulsations are not nearly so distinct.

11. In good spirits, and complains only of the dyspnoea. The pulsations of the tumour cannot now be felt at the space between the sternal and clavicular attachments of the sterno-mastoid, and they are much more feeble above the sternum. Appr. *Empl. lyttæ. parti superiori sterni, et cont. Haust. ether. et tr. opii. h. s.*

19. Has been going on well since the last report. The dyspnoea was entirely relieved by the blister, and has not since returned, and the cough is nearly gone. Her nights are good; she sits up during seven or eight hours daily, and her breathing is not affected by the exertion of walking about, or going up and down stairs. The tumour still pulsates, but seems to be gradually diminishing in size. Pressure on the subclavian makes her breathing "thick," as she calls it, but not produce any thing like the distress it would have occasioned a week ago.

27 It is now a month since the operation was performed. The patient walks out daily; her difficulty of breathing is entirely removed, and only returns, slightly, if she walks fast. The tumour still pulsates distinctly, but any pressure upon it does not give rise to dyspnoea, or inconvenience of any kind. She sleeps well at night, and has for the last ten days been entirely without medicine. She has expressed a wish to return to her friends at Burton, and as she appears to be so well, I have permitted her to do so.

The further progress of this case I shall of course be glad hereafter to communicate. I have written to my friend Mr. Tomlinson, of Burton, and requested him

to keep an eye upon it, and I shall also myself take an opportunity of seeing it occasionally.

So far even the case is one of no ordinary interest, as it tends strongly, with the cases already published, to determine, at all events, one important surgical question, *viz.*, the curableness of what has till lately been considered incurable,—aneurism of the arteria innominata; and it also bears upon the general question of the propriety, in every case, of attempting the cure of aneurism by ligature of the vessel on the distal side of the disease.

The operation on the present occasion was performed according to the principle originally proposed and adopted by Mr. Wardrop; but there seems to exist some misconception relative to the position which it occupies as a surgical proceeding.

Admiring the talent and sound judgment of Mr. Fearn in reverting to the operation in question, we may point out that his *principles* were not those which were originally explained as being applicable to similar cases. Mr. Fearn, and some other surgeons, have confounded Mr. Wardrop's operation with that which was proposed by Brasdor.

The three different operations for aneurism are those of Hunter, Brasdor, and Wardrop, each essentially differing from one another.

Hunter's operation consisted in placing the ligature on the artery, at a considerable distance from, and on the cardiac side of, the tumour.

Brasdor proposed, in such cases of aneurism of the extremities as were so situated that there was not room enough to apply a ligature on the cardiac side of the tumour, to place the ligature on the distal, or what is more technically called the "capillary," side of the aneurism. Though that mode of operation had already been proposed nearly sixty years, it had been performed only three times throughout Europe, on all which occasions it proved unsuccessful, until twelve years ago, when it was revived, and successfully employed, by Mr. Wardrop, in several cases of aneurism of the carotid, for which artery it is undoubtedly particularly applicable.

But the operation which Mr. Wardrop afterwards proposed was founded on a totally different principle, and perfectly distinct, from the operations both of Hunter and Brasdor. Mr. Wardrop was led to perform the new operation for the

cure of aneurism, by a chain of reasoning deduced from observations made on the results of Hunter's operation, and also from the phenomena observed in the spontaneous cure of aneurism. Many cases where recorded wherein Hunter's operation was successfully performed, but in which it was afterwards found that the artery on which the ligature had been placed was not sufficient altogether to prevent the circulation of the blood within the aneurismal tumour, the circumstance of a *diminution* in the velocity of the blood within the tumour being sufficient to permit its coagulation to take place for the cure of the disease. He further observed, that when aneurism was cured by a spontaneous process, nature sometimes effected her purpose, not by a *complete* interruption of the circulation within the tumour, but by diminishing it to such a degree as to cause its coagulation. Hence he justly concluded, that in cases of aneurism thus circumstanced, when a ligature could be placed neither on the *cardiac* side of the tumour, as proposed by Hunter, nor on the artery on the *capillary* side of the tumour, as proposed by Bransdor, a diminution in the force of the circulation, sufficient to permit the coagulation of the blood within the tumour, would be effected by placing a ligature on the capillary side of *only one branch* of the diseased artery. When, for instance, the *arteria innominata* is the seat of aneurism, and when it is impracticable to place a ligature on that vessel, either on the cardiac or on the capillary side of the tumour, Mr. Wardrop conceived that if the circulation, either through the carotid artery alone, or through the subclavian artery, could be arrested, then such diminution would take place in the force of the circulation within an aneurism of the innominata, that a gradual coagulation of the blood would be ensured, fortifying the parietes of the tumour, and so preventing the bursting of the sac. This operation Mr. Wardrop successfully performed in the memorable case of Mrs. Denmark. The soundness of the principles on which the operation is based,—the correctness of the reasoning which led to its original adoption,—and its utility as a surgical proceeding, have received remarkable and important confirmation.—*Lancet*.

THE ANATOMIST.

THE SKULL,

Consists of eight bones, four of which are symmetrical, viz. the frontal, the ethmoid, the sphenoid, and the occipital; and four arranged in pairs, viz. two parietal, and two temporal.

FRONTAL BONE.

Situation.—Upper and anterior part of the skull.

External, or frontal aspect, is convex and arched, and presents a median vertical depression, which marks the original division of the bone into two.

Nasal spine, at the inferior part of the median depression or line.

Frontal eminences, on either side of the median line marking the points of ossification of the bone.

Superciliary arches, two convexities which extend for about an inch on either side of the median line inferiorly.

Eminence of frontal sinuses, between, but a little above the superciliary arches.

Orbital arches, form the upper edges of the orbits, and present towards their inner thirds the supra-orbital holes or notches, for the passage of the frontal nerves and arteries.

External angular processes, at the outer terminations of the orbital arches.

Internal angular processes, at the inner termination of the orbital arches.

Temporal ridges, extend backward and upwards from the external angular processes.

Internal or cerebral aspect, is concave, and presents in the median line a groove, which corresponds to the longitudinal sinus.

Crest, at the commencement of the median groove: it gives attachment to the falx.

Foramen cecum, at the root of crest, gives passage to a vein from the nose, which opens into the longitudinal sinus.

Eminences and depressions, on either side of the median line, corresponding to the convolutions of the brain.

Orbito-ethmoidal aspect, is irregular, forming on either side part of the orbits, and in the median line part of the nose.

Ethmoidal notch, quadrilateral, articulates with the ethmoid bone by a serrated margin; its edges being cellular to unite with the ethmoidal cells.

Anterior and posterior ethmoidal holes, along the margins of the ethmoidal notch,

giving passage to the nasal twig of the ophthalmic nerve and the ethmoidal arteries.

Orbital processes, triangular, and on either side of the ethmoidal notch, form the roofs of the orbits by their smooth concave surface, and on their convex surface are marked by the convolutions of the brain. Their upper and outer surfaces are deep for lodging the lachrymal glands, and at the nasal margin of each is a depression for the reflected tendon of the superior oblique muscle.

Frontal sinuses, at the antero-inferior part of the bone, and between its two tables; they open at either side of the nasal process.

PARIETAL BONES.

Situation, upper and lateral parts of cranium, being quadrilateral.

External surface, convex, and marked by a semicircular ridge, which is continued from the temporal ridge of the frontal bone.

Four edges. The upper is the longest, and joins its fellow,—the anterior joins the frontal bone,—the posterior is very irregular, and joins the occipital,—and the inferior is thin and semicircular, and joins the temporal bone.

Four angles. The anterior inferior is long and curved, and joins the sphenoid bone; upon its cerebral aspect a canal or a groove exists for the trunk of the middle meningeal artery. The posterior inferior angle is grooved upon its cerebral aspect to lodge part of the lateral sinus. The superior angles are rather rounded.

Internal surface, concave, and marked by the convolutions of the brain and the ramifications of the middle meningeal artery, presents along its upper edge a shallow groove, which, with its fellow, accommodates the superior longitudinal sinus; external to this groove are depressions marking where the glandulæ Pachioni were situated.

OCCIPITAL BONE.

Situation, posterior and inferior part of cranium.

Tuberosity, near the centre of external surface.

Superior transverse ridge, leads from either side of the spine.

Inferior transverse ridge, midway between spine and foramen magnum.

Spine, leads from tuberosity down to foramen magnum.

Foramen magnum, larger internally than externally, is of an oval form, and

transmits the medulla spinalis, vertebral arteries, and sub-occipital nerves.

Basilar process, passes forwards and upwards to join the sphenoid bone, is rough inferiorly for the attachment of the pharynx; and upon its cerebral aspect is smooth and concave from side to side to support the pons varolii and basilar artery.

Condyles, smooth and oblong, look downwards, outwards, and backwards, and present roughness internally for the moderator ligaments.

Anterior condyloid foramina, situated before the condyles for the passage of the ninth pair of nerves.

Posterior condyloid foramina, behind the condyles for the passage of veins and twigs of arteries. These are sometimes absent.

Jugular eminences, external to either condyle.

Crucial spine, on the cerebral aspect, and formed by a transverse and vertical line, gives attachment to the falx major by the upper half of the vertical line, in which is a groove for the termination of the longitudinal sinus, and to the falx minor by its lower half; the transverse ridge giving attachment to the tentorium, and also presenting a groove on either side for the lateral sinuses.

Four fossæ, two superior for the posterior lobes of the cerebrum, and two inferior and deeper for the cerebellum.

Grooves for inferior petrosal sinuses, one on either side of the cerebral aspect of the basilar process.

Grooves for the termination of the lateral sinuses, on each side of the foramen magnum above the jugular eminences.

TEMPORAL BONE.

Situation, at the lateral, middle, and inferior part of the skull.

Squamous portion, semicircular, flat, and thin, forming part of the side of the skull and of the temporal fossa.

Zygomatic process, arises by two roots, one anterior bounding the front of the glenoid cavity, the other posterior, which is bifurcated. The process then passes forwards, and presents a serrated edge to unite with the malar bone.

Zygomatic tubercle, is situated at the union of the zygomatic roots.

Trachlea, between the root of the zygomatic process and the squamous plate, for the passage of the temporal muscle.

Glenoid cavity, transversely oval, and

deep anteriorly for the reception of the maxillary condyle, and shallow behind, where it lodges a portion of the parotid gland.

Glossarian fissure, crosses the glenoid cavity in a direction obliquely forwards and inwards.

Auditory process, commences by the external meatus, and leads inwards and forwards to the membrana tympani, and presents an external rugged edge for the attachment of the cartilage of the ear.

Internal surface of squamous plate, is marked by the convolutions of the brain and blood vessels.

Mastoid grooves, at the posterior and inferior aspect of the bone.

Mastoid process, internal to the mastoid process for the occipital artery and posterior belly of the digastric muscle.

Mastoid foramen, posterior to mastoid process for the transmission of a vein.

Mastoid fossa, in the cerebral aspect for the lateral sinus.

Mastoid cells, in the interior of mastoid process.

Petrous portion, extends forwards and inwards, and presents three aspects, being of a prismatic form.

Aqueduct of the cochlea, a minute foramen on the under surface posterior to the styloid process.

Styloid process, long and tapering, descends obliquely forwards and inwards.

Vaginal process, a plate of bone between the glenoid cavity and the carotid foramen.

Stylo-mastoid foramen, between the styloid and mastoid processes for the passage of the portio dura nerve.

Carotid canal, commences in front of the styloid process, and turns forwards, upwards and inwards, and terminates by the side of the body of the sphenoid bone.

Processus cochleaniformis, a thin plate of bone separating two canals, which are situated in the angle between the petrous and squamous portions; the superior of which transmits the tendon tympani muscle; the inferior is the bony part of the eustachian tube.

Superior petrosal ridge, separates the anterior from the posterior surface, and gives attachment to the tentorium.

Depression for Gasserian ganglion, on the anterior extremity of the superior surface.

Histius Fallopii, a foramen on the superior surface for the passage of the vidian nerve.

No. 6.

Meatus auditorius internus, on the posterior surface, for the transmission of the seventh pair of nerves.

Aqueduct of the vestibule, a small slit-like opening posterior to the meatus internus.

The superior semicircular canal, forms an eminence on the superior petrosal surface.

ÆTHMOID BONE.

Situation, in the æthmoidal notch.

Crista galli, a perpendicular process which divides the cerebral aspect into two equal portions, and to which is attached the commencement of the falx.

Cribiform plate, on either side of the crista galli, concave to lodge the olfactory bulbs, and perforated with holes for the passage of the filaments of the olfactory nerves, the nasal division of the ophthalmic nerve, and some small blood vessels.

Nasal plate, descends from the under surface of the crista galli; joins the sphenoid bone posteriorly, the vomer and nasal cartilage inferiorly, and the os frontis and nasal bones anteriorly.

Orbital plate, a smooth square plate of bone situated externally, and forming part of the orbit; in its upper edge are often found two notches, which, with those in the frontal bone, form the internal orbital foramina.

Æthmoidal cells, between the orbital plate and the nasal plate, are ten or twelve in number.

Superior spongy bone, descends in a curved manner outwards from the upper and posterior part of the bone, forming a short channel, called the superior meatus of the nose.

Middle spongy bone, larger and more curved, descends outwards, forming the middle meatus of the nose.

Infundibulum, a smooth groove leading from the anterior æthmoidal cells to the middle meatus.

SPHENOID BONE.

Body, corresponds to the median line, and presents six aspects.

Posterior aspect, is rough for connexion with the basilar process of occipital bone.

Anterior aspect, presents the openings of the sphenoidal sinus.

Inferior aspect, presents the *azygos process*, which articulates with the vomer.

Superior or cerebral aspect, presents a fossa, called *sella turcica*.

Lateral aspects, join the great ala.

Sella turcica, a deep fossa on the cere-

bral aspect of the body for lodging the pituitary gland.

Posterior clinoid processes, two rounded eminences posterior to the sella turcica.

Anterior clinoid processes, two rounded eminences situated external and anterior to the sella turcica.

Olivary process, an eminence between the anterior clinoid processes, and anterior to the sella turcica, on which the optic commissure rests.

Carotid grooves, one on either side of the sella turcica for the internal carotid arteries.

Transverse spines or lesser wings, two thin plates of bone extending forwards and outwards from the anterior clinoid processes, presenting anteriorly a spine in the median line, to unite with the ethmoid bone, and a serrated margin on either side to unite with the frontal bone. Their posterior free edges afford attachment to the sphenoidal fold of the dura mater. The external extremity of each terminates in an acute point, and their cerebral aspect is smooth to support the anterior lobes of the brain.

Great wings, extend laterally from the sides of the body; each presents three aspects, one anterior and smooth to assist in forming the outer part of the orbit, the second posterior, concave, and marked by cerebral convolutions, to assist in forming the middle cranial fossa, and the third external, being divided by a crest, the portion above the crest forming part of the temporal fossa, and the portion below part of the zygomatic fossa.

Spinous processes, extend backwards and outwards from the posterior termination of each great wing.

Pterygoid processes, two on either side, descend from the angle of junction of the great ala and the body. The external is broad and irregular; the internal is long and narrow, and terminates in a hook called the mamular process.

Pterygoid fossa, is the hollow between the pterygoid processes posteriorly.

Foramina lacera, on either side of the sella turcica, are placed between the greater and lesser wings; each gives transmission to the third, fourth, first branch of the fifth, and the sixth pairs of nerves, and to the ophthalmic vein.

Foramina optica, at the roots of the lesser wings, give passage to the optic nerves and ophthalmic arteries.

Foramina rotunda, posterior, and a little external to the bases of the foramina lacera, give passage to the second division of the fifth.

Foramina oval, near the posterior terminations of the great wings, give passage to the third division of the fifth.

Foramina spinosa, in the spinous processes, give passage to the middle meningeal artery of either side.

Foramina pterygoidea, at the roots of the pterygoid processes, for the passage of the vidian nerves.

BONES OF THE FACE.

MALAR BONE.

Situation, at the outer and under part of the orbit, forming the cheek.

External surface, convex, and of an irregular quadrilateral form.

External angular process, at the upper and outer edge, joins the frontal bone.

Maxillary process, serrated, and at inner edge rests on the superior maxillary bone.

Zygomatic process, passes backwards, and supports the zygomatic process of the temporal bone by a serrated edge.

Upper edge, forms the outer and inferior margin of the orbit.

Orbital process, a thin plate of bone, which passes from the upper edge backwards and inwards.

Lower edge thick and uneven for the attachment of the masseter muscle.

Temporal aspect, behind the zygomatic process, is smooth for the lodgment of the temporal muscle.

Two or three foramina, on its cutaneous aspect for vessels and branches of lachrymal nerves.

SUPERIOR MAXILLARY BONE.

Body, quadrilateral, presents anteriorly the canine fossa.

Malar Process, externally and superiorly, presents a rough surface which supports the malar bone.

Nasal process, internally and superiorly, is serrated above to join the frontal bone, and also presents a groove to support the nasal bone. Its cutaneous aspect is perforated by two or three small holes for blood vessels, its posterior aspect is deeply grooved to assist in forming the fossa for the lodgment of the lachrymal sac and duct and its internal or nasal aspect is divided by a ridge, which supports the inferior spongy bone.

Orbital plate, triangular, assists to form the floor of the orbit.

Infra-orbital canal, passes forwards between the plates of the orbital process and terminates in the *infra-orbital foramen*.

Temporal aspect, presents behind the malar process a smooth depression for the temporal muscle and more posteriorly and inferiorly a *tuberosity* which corresponds to the dens sapientie.

Posterior dental foramina are three or four small holes which give passage to the posterior dental nerves; and are found near the tuberosity.

Palatine process is thick internally and rough where it joins its fellow, its circumference corresponds to the alveolar processes, and its posterior edge is thin and serrated where it joins the palate bone; its upper surface is smooth and concave from side to side, forming the floor of the nose, and its under surface is rough, forming, with the gum, the greater part of the hard palate.

Nasal Crest, at the union of the palatine processes, projects upwards to receive the vomer.

Nasal spine projects forwards, above and between the central incisor teeth.

Foramen incisivum, is common to both bones and exists inferiorly at the anterior union of their palatine plates; superiorly it bifurcates and opens by two foramina one in each nostril.

Antrum maxillare a large cavity in the body of the bone, bounded above by the orbital plate, below by the alveoli of the molar teeth, anteriorly by the canine fossa and posteriorly by the temporal aspect: externally it corresponds to the molar process and internally it presents a large irregular opening.

PALATE BONE.

Horizontal or palate plate, quadrilateral, is concave and smooth above, and completes the floor of the nose, and rough below where it completes the hard palate. Its anterior edge is serrated to join the superior maxillary bone, its posterior edge is concave and gives attachment to the soft palate, its inner edge is serrated where it joins its fellow and sends a *crest* upwards to support the vomer and its outer edge joins the nasal plate.

Nasal spine projects backwards from the union of the palate plates.

Nasal process, broad and thin, its inner surface is divided into two by a ridge which supports the inferior spongy bone: above and below the bone is slightly concave to assist in forming the inferior and middle meatuses. External surface is rough and marked by the posterior palatine vessels and nerves. Anterior edge, thin, assists to close the antrum and the posterior edge joins the pterygoid process.

Pterygoid process, the thickest part of the bone, of a wedge shape, inclines backwards and outwards; it presents three grooves, a central one smooth which completes the pterygoid fossa and a rough one on either side to articulate with the extremities of pterygoid processes.

Palatine foramina, at the junction of pterygoid and palatine processes for the transmission of the palatine nerve and vessels.

Orbital process, surmounting the nasal process is divided into two by a notch, which forms with the sphenoid bone the *pheno-palatine hole*.

Anterior orbital process, is the largest, being hollow and of a triangular form; it forms the posterior part of the floor of the orbit by its upper smooth surface; it joins the orbital plate of the superior maxillary bone and the os planum of the ethmoid bone by its two serrated edges; its smooth edge looking towards the speno-maxillary fissure.

Posterior orbital process, articulates with the body and spongy plate of the sphenoid bone and is also hollow.

INFERIOR SPONGY BONE.

Rough and convex towards the septum of the nose and concave externally, presents a free margin inferiorly and is attached above to the os unguis, and to the ridge on the superior maxillary and palate bones. It perfects the nasal duct inferiorly.

OS UNGUIS.

Situation, inner and anterior part of orbit.

Edges serrated to join the os frontis above the maxillary bone below the nasal bone anteriorly and the ethmoid bone behind.

External surface, divided by a perpendicular ridge, presents a groove anteriorly for the lachrymal sac and a smooth surface behind to assist in forming the orbit.

Internal surface, covers in the anterior ethmoidal cells.

NASAL BONES.

Situation, beneath the nasal process of frontal bone and between the nasal processes of superior maxillary bones.

External surface, convex and presents small foramina for blood vessels.

Internal surface, concave is grooved by the nasal nerves.

Superior edge thick and serrated to join the frontal bone.

Inferior edge thin and expanded joins the lateral nasal cartilages.

External edge is the longest serrated to join the superior maxillary bone.

Internal edge is flat and joins its fellow.

VOMER.

Situation in the medium line of nose.

Superior edge grooved to receive the *azygos* process of the sphenoid bone.

Anterior edge slightly grooved to receive the ethmoidal plate and nasal cartilage.

Posterior edge free, looks towards the pharynx.

Inferior edge the longest, is received into the nasal crest of the superior maxillary and palate bones.

INFERIOR MAXILLARY BONE.

Body is the anterior portion projecting inferiorly into *mental process* or *chin* superiorly surmounted by alveoli of four incisor teeth,—anteriorly having on each side a depression for muscles—posteriorly, eminences and depressions for muscles.

Symphysis is a vertical ridge in the centre of body.

Horizontal rami. On outer surface of each is an oblique ridge for muscles; on the inner is mylo-hyoidean ridge above which is a depression for sublingual gland and below for sub-maxillary gland.—The lower edge is rounded and grooved for facial artery, upper edge has alveolar processes.

Angle is obtuse and rough for muscles.

Ascending rami are thick and round posteriorly—externally smooth—internally grooved.

Coronoid process passes upwards from anterior part of ascending ramus.

Condyle is a process transversely oblong to articulate with temporal bone.

Neck constricted part below condyle.

Process semilunar notch between condyle and coronoid.

Inferior dental foramen situated at interval surface of ascending ramus and surmounted by a *spine*.

Mental foramen situated at anterior surface of bone external to body.

Dental canal traverses bone between the two foramina, and communicates with each alveoli.

OS HYOIDES.

Situation in the anterior part of the neck between the chin and larynx.

Body square, is rough anteriorly for

muscles, and smooth behind where it corresponds to the epiglottidean gland.

Greater cornua, pass obliquely upwards and outwards from the sides of the body.

Lesser cornua are very small and pass obliquely backwards and upwards from the point of junction of the great cornua and body.

The bones of the ear are described in connection with the organ of hearing.

The London Medical

AND

Surgical Journal.

Saturday, May 13th, 1837.

WORKING OF THE IMPROVEMENTS OF THE ROYAL COLLEGE OF SURGEONS.

Since the museum of the Royal College of Surgeons was thrown open to the Public we refrained from offering any observations upon the new building, the classification of the preparations, or the attention of those who are commissioned by the Council to superintend the new arrangements, until we had satisfied ourselves, by repeated visits, of the manner in which the entire was conducted.

Of the building itself, it is sufficient to say that ample accommodation has been provided for the display, not only of the labours of the immortal Hunter, as well as for the other additions which have been made, from time to time, by the College, but from the excellent manner in which the temperature is maintained, security is given to the preservation of the numerous specimens contained within its walls, and the plan on which the whole building is lighted, shews the various preparations to the best possible advantage.

Too much praise cannot be given to the Council for their liberality by opening their doors to the Profession at large, and to the Public generally, by an introduction from a member. When it is considered the great length of time that the Hunterian Museum was confined to the inspection of a select few of the corruptionists, a proceeding of the greatest danger to the community, and a strong temptation to even the most honest individuals to avail themselves of the labours of another, a fraud which cannot now be at least so easily practised upon the Public.

With regard to the attendance of the officers, too much praise cannot be given them, for their assiduity and polite attention, and their anxiety to give the visitors every information on the various preparations, whilst the voluminous catalogues, drawn up with such simplicity and skill, render, even to the student, every facility of acquiring an acquaintance with the vast field of knowledge which this magnificent collection offers to his mind for investigation.

In our visits, we had not the pleasure of meeting the able and learned Professor of Comparative Anatomy, Mr. Owen, as often as we could have wished, but his absence at this time can be well explained, when we reap, in a short hour, the "concentrated essence" of labour, which must have cost him the most extensive investigation and the deepest research. Without a desire to make an invidious comparison, the lectures which Mr. Owen has already delivered form a striking contrast with those morbid and offensive compositions which immediately preceded them. We had almost neglected noticing the constant presence in the Museum of one whose affability and desire to impart information have never been surpassed. Mr. Clift, like a second

Simpson, gracefully moving under the azure canopy at Vauxhall, "in the 65th year of his age," seems to live only in the atmosphere of the building which contains the Hunterian collection, and which we hope he will continue to adorn by his presence for many years to come.

We were quite unprepared, notwithstanding the investigations of Mr. Warburton's Committee, for the gigantic strides in liberality which have induced the Council to establish a reading-room. The room is now open to the members three successive evenings in every week, from seven to ten o'clock; and though this limited period may have appeared to the learned members of the Council quite adequate to supply the public appetite for intellectual food, and afford them quite sufficient time to ponder over the luminous contributions which are so abundant in the pages of the *Lancet* and the *Medical and Surgical Journal*, and prosing fabrications of the *Gazette*, yet this was but a sparing allowance, and quite inadequate to glut the bulimic appetites of the commonalty. When the doors of the reading-room were first thrown open, many distinguished individuals thronged to partake of the intellectual feast, and we can only account for the gradual, though progressive diminution to the limited hours, which the Council have appropriated for the repast. It is indeed our painful duty to state, that of the multitude who thronged the portals of Lincoln's-Inn Fields, only one has had the courage to continue his attendance in the room at the prescribed hours, in justice to whom it is but fair to state, that he has been induced to continue his attendance, not being able to satiate his appetite, but because he can partake of fare which he could not procure elsewhere but at considerable expense.

The attention of Dr. Willis in the library needs no comment. His wonted courtesy and kindness have long given universal satisfaction.

The accommodations for the pupils and members who have business to transact at the College, are in keeping with those of the museum and library; whilst the urbanity of Mr. Belfour, and those in his department, is, if any thing, more remarkable than when he graced the office in the old building.

To refer once more to the reading-room. We trust the Council will see the necessity of rendering it more worthy of their boasted interest in the welfare of the members, to enlarge the period of attendance, and to make it much better known by more public notification than has hitherto been given.

GENERAL CONSIDERATIONS

ON THE DISEASES OF CHILDREN AND THEIR THERAPEUTIC.

Hospital for sick Children.

OF all the diseases observed in the hospitals of Paris, none seem to call for more special attention, or to afford greater interest to the practitioner than the study of diseases incident to childhood: there is an hospital in Paris expressly adapted for sick children. No idea can be formed of the number and variety of acute and chronic affections met with in this establishment, especially in the ward we intend to review, which may be considered one of the most curious in the hospital, on account of the number of children, and the nature of their complaints. Dr. Baudelocque's wards are divided in acute and chronic diseases. The first division contains about sixty beds, occupied by children from two to fifteen years of age. A ward of thirty beds is destined to older children; another ward contains children under five; and nervous diseases, epilepsy, chorea, convulsions are attended to in another ward.

The division of chronic diseases com-

posed of three small wards contains those patients who are scrofulous, or who have diseases of the skin. This part of the service is the most interesting, owing to the pains M. Baudelocque takes in the treatment of these children, and by the variety and multiplicity of medications he employs. All the patients in this ward are girls.

Among affections so numerous, and so various, we shall be puzzled which to choose; we shall put aside all facts which are not immediately practical, and merely make our readers acquainted with what is eminently useful.

M. Baudelocque does not seem to approve of active medications in acute diseases of children; he is of opinion (excepting in certain circumstances we shall take care to note) that when these juvenile patients are put in a suitable condition, the disease goes through its different stages, and nature powerfully assists the cure. For bronchitis, angina, and in general all eruptive diseases, the best remedy is to observe children, to put them on moderate diet, and keep them from all stimulating causes. If for example, a child has the whooping cough, he does not bleed, unless the young patient be very strong and full, or that there is some serious complication; a moderate diet is prescribed, emulsions, and a few doses of white oxyde of antimony. With this treatment the attacks become slight, and the whooping cough gradually disappears.

The same remarks are applicable to angina preceding scarlatina, bronchitis which is generally the forerunner of the measles. Blood-letting is very seldom prescribed in these cases. Dr. B. thinks it is better avoided, and he observes that in cases where leeches have been recommended, and that the recommendation has been neglected, the patients have nevertheless been cured.

We must however state that Dr. B. has more frequently recourse to bleeding in his private practise than in the hospitals: the children of the indigent are of a much weaker constitution, and seldom need the same antiphlogistic treatment as the opulent.

Dr. B. does not think an acute malady can be got rid of by profuse bleeding. Its intensity may be diminished, its complications decreased, but to arrest it suddenly by bleeding is not possible. In a typhus fever for instance, neither sanguine evacuations, nor purgatives can arrest the progress of the disease, it must

have its course, and if bleeding be not injurious, it is at all events useless.

But however cautious and timid Dr. B. may prove in acute diseases of children, he is equally active in the treatment of chronic diseases, employing alternately, the most active and varied medications, and neglecting none of the resources of medicine. The division of chronic disease is not assuredly the least interesting, and before we trace their particular history, we must cast a rapid glance on the different indications in general use.

Dr. B. frequently employs purgatives in the chronic diseases of children; there are certain affections for which he only prescribes opening medicines, and for most others, purgatives are nearly always combined with the different remedies he recommends.

Purgatives considered as a method of treatment, are usually given to children, and all other medicines are excluded, when they have for any given time been accustomed to take any medication. Aperient draughts are then to be administered twice a week; but if the child be under any other course of medicine, it must be suspended the day on which the purgative is taken.

These purgatives may be continued for several months without any fear of accident, the children do not appear to suffer, their appetite is not diminished, and we have seen several scrofulous patients who during two or three months were regularly purged twice a week, without the digestive tube having the least suffered from it. Certain diseases have been completely cured by this simple medication, others have seen their symptoms considerably amended, and the cure has been rapidly achieved by means of other remedies.

It is rather difficult to make children take medicine, owing to its disagreeable taste; Dr. B. has found the following prescription made up with coffee, answer the desired purpose, for it is by no means unpleasant to children, to whom it should be given early in the morning, and their breakfast sometime after.

Senna ʒiij.

Water four ounces.

To be mixed with coffee, to which a little milk should be added.

This purgative has a good effect, children take it with pleasure, and it generally procures eight or ten stools without colics. *Manna*, or sulfate of soda, is sometimes substituted for senna.

It is rather the fashion at present to prescribe syrup of acorns, which was lately termed a *precious tonic*.

This syrup is extracted from acorns, torrefied and reduced to a powder, of which a syrup is made.

A decoction of hops so frequently prescribed for children, and taken so reluctantly, has been replaced by *oxymel scillitic*.

Iodine, extract of hemlock, arseniate of soda, barytes, &c. &c., are medications frequently employed by Dr. B. Our readers will be enabled to appreciate the value of these substances by the numerous cases we shall bring forward. In the mean time we shall say a few words on the manner of administering them.

The extract of hemlock is generally given in doses of four to twelve grains; which dose is increased gradually, and as much as thirty or forty, or even sixty grains may be taken. No accident had ever occurred from the administration of this medicine, when not long since, all the patients who had taken it, were on the same day seized with head-aches, vertigo, and other symptoms of poison. These accidents were attributed to a change in the mode of preparation, the apothecary having that day made use of a new extract.

The arseniate of soda is at this present time prescribed for a girl of twelve, who has a lupus on her nose. After removing the scab with soothing poultices, cauterization with hydrochloric acid has been resorted to, the treatment with arseniate of soda, was then commenced, and we have not yet had sufficient time to judge of it correctly; at a future period we shall give an account of its results.

A little girl of eight years old, having a white swelling of the iliofemoral articulation, takes muriate of barytis, two ounces of solution of muriate of barytis in two doses, one in the morning the other in the evening, each ounce of solution contains one grain.

Although muriate of barytes has been lately given in enormous doses, M. Baudelocque has never been able to prescribe more than four grains without danger. Chronic ophthalmia are very numerous—several practitioners have lately prescribed tincture of *Rhus toxicodendron*.

Children affected with chorea and epilepsy are also very numerous. M. Baudelocque has obtained great success with sulphuric baths in St. Vitus' dance; he has also administered sulphate of quinin.

ine to a girl of twelve, who had long been subjected to vertigo, these attacks were very similar to those of chorea, her arms and legs were convulsed; she recovered in a few minutes, and appeared in a state of perfect health.

Generally those children treated in the wards of chronic diseases, are subjected to an alimentary diet, and eat according to their appetite; unless a complication arises, they have wine and meat. Those who are affected with acute diseases are very seldom put on low diet, experience having proved that the privation of good nourishment during any length of time, is very prejudicial to growing children. Thus milk, eggs, vegetables, meat, are given with due regard to the digestive faculties of the juvenile patients.

ON THE CURE OF HEADACH BY THE APPLICATION OF LEECHES TO THE SCHNEIDERIAN MEMBRANE.

BY JOHN WALKER, M.D.

THE frequent failure of general bleeding, by the application of leeches to the head, and likewise of counter-irritants in relieving the severe frontal headaches arising from congestion of the brain and its membranes, induced me to give extensive trial to the detraction of blood from the ethmoidal vessels, by means of leeches applied to the schneiderian membrane (as recommended by Mr. Wardrop in his Treatise on Blood-letting), and I have found the results very generally beneficial.

As the pericranium is almost entirely supplied with blood vessels from the neck, it is natural to conclude that blood detracted from it, will not in general alleviate the symptoms arising from internal congestion and other painful affections of the cerebrum, unless it is taken in such quantity as will greatly reduce the force of the circulation, which would require the application of a large number of leeches, attended with great loss of time and inconvenience; and I am inclined to think that the beneficial effects frequently attributed to the application of leeches to the head, are to be ascribed in many cases to the employment of general blood-letting, cold applications, and other collateral measures.

In abstracting blood from this part, we only follow the plan adopted by nature, in relieving by epistaxis, not only congestion of the brain, but apoplectic and other attacks. Even in the more remote

parts of Scotland, when a person is seized with apoplexy in the absence of medical aid, some one of the bystanders endeavours to produce epistaxis, by inflicting a smart stroke on the patient's nose, thereby relieving the gorged state of the cerebral vessels. Mr. Wardrop mentions the case of an empiric, who had apparently become famed for his successful treatment of headach, which consisted in scarifying the schneiderian membrane. I have found most benefit from this mode of treatment in the painful headaches peculiar to pregnant females; in those arising from irregularity or total suppression of the catamenia in plethoric habits, and in a few depending upon biliary derangement.

The following are only a few cases selected from my notes:—

Mary Wilson, æt. 19. Catamenia became suppressed after exposure to wet and cold, accompanied by considerable pyrexia and severe frontal headach, for which she was submitted to treatment, but with only partial relief. When I first saw her, six weeks afterwards, she still complained of the severe frontal pain, and the catamenial discharge did not flow; she was now repeatedly bled, had leeches frequently applied to the temples; the head was shaved and blisters applied to the back part, which along with the exhibition of medicine, and the use of other means for the purpose of restoring the catamenia, had no effect in abating the pain. A leech was then applied to the membrane of the nose, on each side of the septum, and the bleeding kept up by means of cloths wrung out of warm water, which had the effect of entirely removing the frontal pain; and although her occupation was that of a factory girl, it had not returned at the expiration of three months.

Mrs. Wallace, æt. 24.—In the fifth month of pregnancy, (of her first child,) complained of constant frontal headach. Bowels, &c., regular. A leech was ordered to be applied to each side of the septum of the nose, but being afraid (as she said) that they would creep up her nose, she only applied one, which was followed by complete relief from pain on the corresponding side, and the next day, when a leech was applied to the opposite or painful side, the cure was complete. I have repeated this experiment several times, and with generally the same result.

Mrs. Gillespie, æt. 56.—Has been troubled with asthma during the last twelve years, and has complained of dis-

pressing headach for a period of three years, with a turgid state of the conjunctival vessels, flushed countenance, and a sensation of violent pulsation in the head, so troublesome as at times to prevent sleep. She was requested to apply two leeches to each side of the septum, but could only put on three, the hæmorrhage from which continued the greater part of the night. Next day she expressed herself nearly free from pain; twenty-four hours afterwards other two were applied, which entirely removed the symptoms. In this case the head symptoms returned about every six weeks, when the bleeding was always repeated, and with its usual good effects.

Mrs. Cochrane, æt. 47.—Fifteen months since catamenia became irregular, and for the last three months had entirely ceased. The principal cause of complaint at present is acute frontal pain; two leeches were applied as in the former cases, when she expressed herself well.

Mrs. Bowie, æt. 53.—Has frequently been the subject of all the premonitory symptoms of apoplexy, from which she has as often been relieved by bleeding, &c., but has never been totally free from frontal headach. Eight days since had a return of her head symptoms, from which she was relieved as formerly, but still complained of the constant pain; two leeches were applied to the septum, which in this case bled so profusely that the blood trickled down in a stream; before this troublesome symptom subsided the leeches were applied several times.—*Continental and British Medical Review*.

OBSERVATIONS AND PRACTICAL CONSIDERATIONS ON THE GANGRENOUS STOMATITIS.

The gangrenous inflammation of the mouth in young children, is very common in large towns, especially among the poorer classes. It is, therefore, by no means surprising there should be so many cases of it in the hospital for sick children. During the last six weeks, four affections of this kind have been treated by Dr. Baudelocque, and notwithstanding the danger of this disease,

proved fatal only to one of the four children. We shall give a rapid sketch of the four cases, and show the plan of treatment adopted by Dr. B.

On the 13th of September, a little girl, six years and a half old, was admitted into the hospital, with a cankerous affection of the mouth. This child had been ill for a week, and still had remains of the measles rash; the face was much swelled, the left side edematized, the eyelids nearly closed: in the middle of the cheek there was a sore rather larger than a shilling: inside the mouth was an ulceration, and the whole depth of the cheek was invaded; lower down there was another sore; a dark excretion, of very fetid odour, flowed from the mouth; the gums were swelled and bleeding. Two large sinapisms had been applied to the legs during the measles, and there remained two large gangrenous sores invading the chief part of the teguments of the legs. Auscultation showed that the lungs were seriously affected. The pulse was slow, scarcely perceptible, and a continual diarrhæa contributed to weaken the patient.

Although there could be but little hope of recovery, Dr. Baudelocque had the internal sore cauterized with hydrochloric acid, and externally with a hot iron; the eschars were then to be sprinkled with the powder of chloride of lime. He also prescribed a mixture of a drachm of acetate of ammonia, and an ounce of syrup of quinine, two moderate injections of bark, and the sores of the legs to be powdered with the chloride of lime.

The cauterization was renewed several times. The following day the pulse was better, there was no swelling round the cauterized parts, and the face was less edematized.

On the 26th, the cauterization was again made on the internal sore; four ounces of Malaga wine to be taken by spoonful, were prescribed; the syrup of quinine, the acetate of ammonia, and other means indicated were continued, but the young patient sunk, became delirious, and died on the 28th.

A post mortem examination was made the ensuing day. The perioste of the whole side of the lower jaw to the articulation was detached. The lungs were hepatized in various degrees, and sprinkled with miliary tubercles; the digestive tube was empty.

There was not the slightest chance of saving this patient; the state of the lungs rendered all care useless.

The cauterization, however, seemed to have a good effect on the stomatitis, which made no further progress, the fetid odor no longer existed, a degree of reaction had taken place, but the double pneumonia and excessive suppuration arising from the gangrenous sores on the legs, necessarily led to a fatal termination. In the other three cases this cauterization has been followed by a happier result, though one child was very young, and her state most serious.

A little girl, of five years old, had several gangrenous spots on the cheeks and upper and lower gums. This disease had also made its appearance during the measles. There was cough, fever, diarrhea, and the running from the mouth was so fetid, that it was difficult to examine it.

All the gangrenous parts were touched with hydrochloric acid, and then powdered with chloride of lime. Syrup of quinine, tonic, and antiseptic injections were prescribed. The fetid odour soon disappeared, and the gangrenous spots did not increase. The upper and lower teeth fell out with the mucous, and a large splinter of the maxillary bone, so that after the child's recovery there was a double solution of continuity which seemed to result from two semi-elliptic sections made in the upper and lower jaw.

This cure is undoubtedly very remarkable, and quite unexpected for children of the same age taken into the hospital, and having any severe illness seldom recover.

The other two cases offer but little interest after those just related. A little girl admitted into the hospital, had been ill three months, there was a considerable swelling of the under maxillary ganglia on the left side. When the mouth was opened, several ulcerations of the cheek, the palate, and the tongue were visible; this affection appeared local. The ulcers were touched with hydrochloric acid, then covered with powder of chloride of lime. A gargle of honey and syrup of bark was prescribed.

The progress of this stomatitis was arrested after the second cauterization, and the young patient left the hospital, cured at the end of the week.

The fourth case is that of a little girl, who had two large ulcers in the cheek and on the tongue; the same treatment was followed as for the other child, and she seems to be in a fair way of recovery.

In the two latter patients, the stomatitis

existed independently of any other disease, which does not often occur. This affection is almost always concomitant with an eruption, and especially with the measles, and there are generally serious lesions in the lungs, so that the stomatitis may be considered a dangerous complication, which hurries on the fatal termination.

The digestive tube does not in general show forcible marks of inflammation, and the purging is apparently owing to deglutition of the matter secreted by the gangrenous mucous membrane of the cheek. The preparation of bark appears to be useful in moderating this diarrhea. *Op. cit.*

BIOGRAPHY OF VELPEAU.

Biography seems, perhaps, more essential in the Medical Profession than in any other, for it is not only useful, but indispensable, to be acquainted with the character of the individual who brings forward a case before it is admitted into science; progress depending, in a great measure, on the purity of its origin. We are well aware that it is often easy to judge from a good analysis of a case, whether the statement be correct or not. Yet it is always a painful and laborious task, requiring much time and attention. Without such confidence no progress can be made even in the most exact sciences. J. L. Petit's work would have been much less useful, if the high character and scientific probity of this celebrated surgeon had been less known. However incomplete the cases he relates, they are equivalent to assertions, and given by a man whose word no one ever doubted, they are of real scientific value; while the cases published by Garengot, for instance, never escape suspicion, particularly since the case of the nose that was bitten off, trodden under foot, picked up in a barber's shop, and then successfully grafted on the unlucky face to which it originally belonged. This indeed is a most wonderful specimen of the powers of adhesion!!!

If surgery can boast of having some few worthy imitators of L. Petit, it must also be admitted that there are far more of Garengot's descendants, whose number and whose skill increase daily, particularly in those countries where they are at liberty to practise and make as many dupes as they please.

The biography of men of merit is always interesting, particularly if drawn

by an able pen, and we think our readers will find that M. Vidal de Cassis has fulfilled his task in a most able manner, and we shall therefore lay before our readers his life of Velpeau.

Contemporary biography has an advantage which those who are interested in it, do not sufficiently appreciate. Most men, however upright and honourable they may be, have their enemies, who may give way to their evil passions, and losing sight of all justice, endeavour to cast a stain on those who least deserve it. If the accused has gone through life honourably, he may bring his detractors before the public, and appeal to its judgment. This system of defence is by far the most moral, and the only one to be adopted by an estimable man unjustly accused. If such be M. Velpeau's situation, he may rejoice at it; no one is better able to show what a noble mind can effect. As a surgeon he has risen to the greatest eminence, without ever injuring his brother practitioners, or owing any thing to patronage.

We wish it to be distinctly understood, that in giving the biographical sketches of the eminent professional men still living, we shall rather consider their scientific, than their personal character; and under no circumstances give place to vituperative feelings: our sketches will be selected from men who owe their success in life to their own merit; thus we shall endeavour to encourage the young, or less fortunate practitioners, by laying before them lives of men who, by their actions, evince their elevation of soul, great mental power, and nobly acquire riches and fame.

When Velpeau first arrived in Paris, his poverty was very great, necessity compelled him to make the nicest calculations, in order to provide for his daily wants. Dupuytren's poverty, when he began life, was affluence when compared to Velpeau's. Dupuytren was patronized; Velpeau was indebted to Providence, and his own exertions, for his advancement.

No man was ever more laborious than Velpeau. In 1820, he was admitted to the hospital St. Louis, in Paris, having previously spent four years at Tours. He immediately became a candidate for the *Ecole Pratique*, was elected, and became a professor almost before he was known as a pupil. The ensuing winter he gave lectures on anatomy: he was not led by vanity to make these exertions, but by the necessity of gaining a livelihood, and an anxious desire to obtain information;

both these feelings were equally powerful; his industry knew no bounds. In 1821 he was rewarded for his exertions, and received the prize of anatomy and physiology, and was also named demonstrator of anatomy. He then gave lectures on descriptive and surgical anatomy, but was far from having that command of language he has since acquired.

His desires being very moderate, his manner of living frugal, he soon found himself in good circumstances,—thus being relieved from the uneasiness necessarily attendant on poverty, he gave himself up entirely to his professional pursuits. He then taught operative medicine, and improved himself greatly while teaching others. In 1822, he commenced his researches on embryology, and began with the preparations commanded by the faculty. Velpeau quickly perceived that man, in his intra-uterine life had not been sufficiently studied: this was a fine field for cultivation, and the labour it required did not prevent his undertaking it, and his remarkable ingenuity has brought him the richest collection of embryos, and has given to anatomists a science of which some of the elements were scattered abroad, and others very difficult to find. Velpeau is fully aware that embryology has not reached its apogee; but what science can be said to have attained perfection?

Velpeau's ambition and hopes were realized in 1823. He was then elected, *Agrégé à la Faculté, et Chef de clinique chirurgicale* at the hospital of St. Come, now called *clinique de la Faculté*, and formerly (out of irony) *Hospice de perfectionnement*. Velpeau remained there four years, and attended operations performed by the first surgeons. He used the knife also.

In 1825, Velpeau began to publish his *Anatomie des Regions*, a work abounding in the most exact details, but wanting in method; and if this work showed the author's want of experience, it also displayed a spirit of investigation and application seldom met with in works of anatomists, who too often consider the organs in an abstract manner. Velpeau wished to make a practical anatomy; this intention is evident throughout the work—this praiseworthy tendency to unite anatomy and surgery, has led him occasionally to mistake the one for the other. Nevertheless, an attentive perusal of this work always brings forth fruits that might be vainly sought in publications of the same kind, edited with more

art. This work was brought out in 1826.

In 1828, Velpeau gave up the lectures on descriptive anatomy, and immediately commenced two others: one on surgical anatomy, the other on external pathology. His work on "*Accouchements*," came out the following year, and it is undoubtedly his best production. Velpeau was not yet satisfied, he wished to have his opinions inserted in the medical journals, and he gained his point: he never attacked any one, but was glad to have an opportunity of self defence. His friends wished him to confine himself to science, with which he was perfectly acquainted, but a slight knowledge of the human mind suffices to show the improbability of his so doing. Man is naturally led to undertake what he is the least able to perform. The finest painter of the age insists on playing on the violin, of which he knows little or nothing, but would be quite offended if he were told so.

Whether Velpeau became a journalist through taste, necessity, or error, is not the question: he was a great favourite with the press, his merit was appreciated, his works extolled, his lectures praised. Velpeau then became a candidate for the professorship of physiology, and afterwards for the places obtained *justly* by J. Cloquet, Gerdy, and P. Dubois. Velpeau was always generous to his antagonists; he felt his own strength, he knew his own talents, was supported by the press, and a favourite with the public; he gained his object, and obtained the professorship. It is useless to inquire why a man so idolized one day, should be insulted the next, and what can give rise to the opposition with which Velpeau sometimes meets. Has he forgotten his own origin?—Is he ungrateful to his benefactors? Has he been unjust to his brother practitioners? We think not, his works prove the contrary: and one of their greatest defects, are the numerous citations contained; a sense of justice and benevolence, has thus multiplied them. Velpeau has given to each his due, and always seized an opportunity of bringing forward the name of a *young professor scarcely known*. Thus Velpeau having through his own laudable exertions reached the summit of his profession, like most medical men in France, generously lends his aid to those who commence their career, and gives proofs of his noble mind and feeling heart.—*Op. cit.*

ON URINE.

Some attention was paid to the number of times that a person enjoying good health, and in the middle period of life, is in the habit of discharging urine in twenty-four hours. In the same person we have observed it to vary, without any sensible drangement of the system, from six times to fourteen. I know one gentleman who enjoys very good health, and only discharged his urine twice in twenty-four hours. Nine times is a very common number. The quantity discharged at a time is also very various. The greatest quantity which I have observed a person in perfect health, and under no particular restraint, to discharge at once, is $25\frac{1}{2}$ cubic inches, or somewhat less than a pint: the most common quantity is from seven to nine cubic inches.—*Annals of Medicine*.

I made a comparison between the liquid taken into the stomach and the urine, for five consecutive days. Some days the urine exceeded the liquid food, but, upon the whole, the drink was to the urine as 11 to 10. On one day the drink was to the urine as 100 to 68·2; on another, $73\frac{1}{4}$ to 102·02: nothing, therefore, would be more inaccurate than the inferences drawn from a comparison of the drink and urine for a single day. If my induction be drawn from a sufficient number of days, it is evident that the drink, upon the whole, exceeds the urine by one-tenth part; consequently, if the average quantity of urine be 3·307 lbs., the average quantity of drink will be 3·6377 lbs., or will exceed the urine by nearly one-third of a pound.

I have found diabetic urine to redden litmus, precisely as healthy urine does, though not so powerfully, because the acid is in a much more dilute state.

I may here notice a very remarkable case of diabetes in the Glasgow Infirmary in 1833. The patient was a middle-aged woman, who voided 50 pints of urine in 24 hours. The urine was almost colourless, and had a specific gravity of 1·0285 at 50 degrees; 2597 grains were evaporated to dryness in the vacuum of an air-pump over sulphuric acid; the dry residue weighed 158 grains; or 1000 grains contained 60·8 grains of dry residue. This residue was snow-white, and very adhesive. It had assumed the form of a hollow vesicle, about six inches in diameter, which collapsed when the air was admitted. It was very slightly sweet, exceedingly viscid, and adhered strongly to every

thing with which it came in contact; when digested in alcohol, urea was dissolved, and the sugar remained of a white colour; it blackened when very slightly heated, and, when strongly heated, emitted the smell of burning feathers. This sugar would not crystallize, but it fermented very readily without the assistance of yeast. Professor Thomson of Glasgow on the Urine.—*Annals of Medicine.*

FOREIGN MEDICINE.

SALIVATION TREATED WITH IODINE.

By M. KLOSE.

Salivation had been produced in the cases of two children during their convalescence, by mercury which had been administered on account of inflammation of the brain. To remedy the salivation, iodine was employed; and, after its first two doses, the peculiar smell of the mouth disappeared, the flow of saliva diminished, the pains became alleviated, and the aspect of the ulcers in the mouth was improved. The children were five and seven years of age. The iodine was discontinued before any of its peculiar symptoms were produced. M. Klose thinks iodine of value in such cases; and, as the medicines with which we are at present acquainted appear to possess but little influence over mercurial salivation, when it is once established, a new remedy which promises fairly is worthy of all acceptance.—*British and Foreign Review.*

INTERMITTENT EPISTAXIS CURED WITH QUININE.

A strong man, aged 27, suffered on alternate days from very violent bleeding at the nose, which continued from four to six hours, and could neither be put a stop to, nor alleviated by the common styptics, nor by any of the other means which are usually employed in similar cases. Regarding the periodicity of the occurrence of the bleeding, the treatment was changed, and a large dose of quinine with diluted sulphuric acid, was administered. During the twenty-one days following, the bleeding recurred but twice, and was then readily stopped. The patient subsequently continued quite well.—*Med. Zeitung.*

FRENCH MEDICINE.

Dr. Mühry, an intelligent physician of Hanover, has recently published a comparative view of the state of medicine and surgery in France, England, and Germany, deduced from actual survey.

The subjoined extract from his work in the 6th number of the *British and Foreign Medical Review*,* might be cited to prove the opening soliloquy of Monsieur Argan in Molière's inimitable play, — the "*Malade Imaginaire*", to contain a tolerably fair epitome of French therapeutics at the present day.

"Therapeutics, the end and aim all medical investigation, does not obtain that attention it justly demands in France. How very few internal remedies are permitted according to the dogmas of Broussais, is well known. It is long since the English physicians told their French *confrères* that they allowed their patients to die, while the latter imputed to the former, that they killed theirs. When one hears the prescriptions ordered in the sick-wards of a Parisian hospital he is struck with astonishment at the meagre diet and scanty medicine allotted so each individual.—*Un quart d'une portion, un pain; un bouillon, décoction de riz, sirop de gomme*, constitute at once the nourishment of the patient and the *excipient* for his medicine."—"The supply of victuals is so inconsiderable, that many invalids, especially those suffering from chronic ailments, are heard piteously imploring the physician, while settling their diet-table for the day, to grant them a greater portion of small additional loaf of bread. Indeed they may well complain of pain at the stomach; hunger is the cause of it. The numberless potions forced upon them induce by and bye squeamishness; food is loathed and rejected; and when a cure is accomplished, it is rather through starvation, or withholding aliment, than the employment of medicaments. *Lavemens* of various sorts are on the other hand, in great repute; such as *lavemens purgatis, laxatifs, astringents, calmants, camphrés de belladonne, oxymellés*, &c. Every French practitioner is at any rate so far imbued with *Broussaisism* as to imagine the alimentary canal always more or less affected in disease, and hence bound to abstain from the more efficacious internal remedies. Should neutral salts, calomel, opium, or antimonials be exhibited, it is

* Page 449.

merely for the sake of temporary trial; they soon give place to other things." The practitioner strives rather to procure a victory over the disease than the recovery of the patient; disregarding the general habit of the body for a *localization*, with avidity will he abstract some *palettes* of blood from a subject extenuated by fasting and disease; stifling instead of cherishing the few remaining embers of life. It is thus manifest that if French medicine be pre-eminent in diagnosis based on anatomic-pathological research, it is very far behind in therapeutics."

COPAIBA IN CATARRH OF THE BLADDER.

Dr. Devergie has recorded in the *Gazette Medicale* eight cases of chronic catarrh of the bladder, some of long standing, which were cured by injecting balsam of copaiba, into the bladder. When stricture of the urethra exists, it requires to be remedied before the injections are employed. A drachm of balsam of copaiba, to an ounce of barley-water is strong enough to begin with: when the balsam is combined with narcotics it is less exciting.

Many persons object to the use of copaiba on account of its nauseating property, but this may be corrected in combination.

Frank's Solution of Copaiba possesses the advantage of being free from the nauseating taste of the medicine, and is, therefore, now very much employed in preference to the other preparations of this remedy.

REPORTS OF THE MEETINGS OF MEDICAL SOCIETIES.

SIR,—As one of your early contributors, I cannot help availing myself of this opportunity to express the satisfaction which I, along with many others of your readers in this place, have lately derived from your having given up the practice of filling many of the pages of your journal with the long-winded prosing speechifications of a set of your London ORATORS, who seem to squeeze themselves into every open door to hear the sweet echo of their own voices, and to refresh their visual organs once a week with the sight of their own names in the periodicals. Did any men of eminence, and men who had really useful information to communicate to their professional brethren, attend such meetings, *Reports* would then be of infinite value,

more particularly to your provincial readers; but when I turn over the pages of the *Lancet*, *Gazette*, as well as those of your journal, for some years past, I find nothing but the same loquacious and obtrusive individuals coming forward, not only to speak at every meeting, but at every society in the metropolis.

Your sincere well wisher,
Liverpool, SCRUTATOR.
April 15, 1837.

[We certainly have refrained from giving verbatim reports of these *learned bodies*, though we shall not fail in communicating any thing of interest, which is not likely to occur very frequently. Eds.]

RHINOPLASTY.

A Latin poet, called Calentio, a native of the kingdom of Naples, who lived about the year 1480, writes in the following manner to his friend Orpian:—

"My dear Orpian, if you wish for a nose, come hither as soon as you can, and you will see a thing which is extremely surprising.

"There is one Branca, a Sicilian, who has found out the secret of making noses with the flesh he cuts out of people's arms, or with the noses of slaves who are willing to dispose of them. As soon as I came to the knowledge of what I here tell you, I could not help writing to you immediately about it, for it is the most important news I could acquaint you with. If you will come, you shall have a nose as large as you please. Make haste then, and fly to us.

CASES OF OVARIAN DISEASES.

REPORTED BY MR. EDEN.

CASE 1.

Elizabeth J.—: Mary's Ward, No. 20: admitted Nov. 1831, under the care of Dr. Ashwell: aged 35: unmarried: subject to irregular catamenia for three years, recurring every fortnight, lasting a week, and accompanied by clots: ill 16 months.

On admission—ovarian dropsy: great pain in left iliac region, at commencement: tumour extends from pubis to ensiform cartilage, and into both iliac fossæ: fluctuation distinct: os cervix and body of uterus, healthy.

Treatment—Nov. 2: Julep. Pot. Ni-

trat. Ol. Ric. ʒss. p. r. n.—Dec. 18: Elaterii Ext. gr. ss. t. d. sing. dos. mist.

Progress—Nov. 8: abdomen fuller: parietes not thin enough to tap.—29th: Paracentesis: ten quarts of dark green slimy coagulable fluid.—Dec. 6: left her bed, and doing well—13th: bandage applied.—18th: confined bowels.

Presented. Cyst slowly filling: to go into the country.

Dr. Ashwell saw the patient again about eighteen months afterwards; and the cyst, although tolerably full, was stationary, and had been so many months.

CASE 2.

Mary K—: Mary's Ward, No. 12: admitted Aug. 30, 1832: re-admitted March, 7, 1834: aged 25: married: emaciated, of dark complexion: miscarried four years ago: ill 18 months: was first attacked with pain in right ovary; since which, a gradual and universal enlargement.

At present, distinct fluctuation: cyst very thick at right inferior part: menses regular.

Treatment—Sept. 10: Paracentesis.—20th, ditto. Purgatives, diuretics, occasional opiates, and iodine.—Mar. 7, 1834: again tapped.

Progress—15 pints of fluid evacuated.—Sept. 25: again filling.—20th: 9 pints of fluid withdrawn, not coagulable by head.—Oct. 30: going on well: cyst refilling slowly: urine abundant: great constipation throughout.—Dec. 6: Catamenia appeared after 14 weeks' cessation.—March 7, 1834: 9 pints of fluid withdrawn from one cyst only.

Presented Dec. 1832: again presented March 1834.

In April 1836, Dr. Ashwell saw this woman; and found the cyst only partially full, not requiring paracentesis.

CASE 3.

Jane B—: Mary's Ward, No. 19: admitted Sept. 28, 1832: aged 67: married; no children: very thin: swelling in both iliac regions for four years. One year and a half ago, remained in this ward 12 weeks; and after a long use of the iodine, she diminished nearly to her natural size, from having the appearance of being in the last month of pregnancy. Has since attended as out-patient.

On admission—abdomen painful, and greatly distended with very firm, fluctuating, ovarian cyst: abundant urine. For two years after the solid enlargement of the ovary commenced, there was no

dropical effusion: the fluctuation has only been evident during the last 24 months.

Treatment—Julep. Iodinii cum Tinct. ejusdem, et Pot. Hydriod. Casc. cum Sod.

Progress—Urine abundant throughout; the abdomen much diminished in size; giddiness in the head, &c., from iodine.

Since this period, the iodine has been more or less constantly administered; and the fluid in the cysts has been restrained from any great accumulation. The solid growth on the right side of the lower part of the abdomen is stationary, although still of great size.

CASE 4.

Caroline D—: Mary's Ward, No. 18: admitted Sept. 6, 1834, under the care of Dr. Ashwell: aged 27: fair: always healthy: married 10 years: 3 natural labours: regular but difficult menstruation: leucorrhœa: hæmoptysis, from straining 4 years ago, followed by swelling in right iliac region 12 months after last labour: swelling rapidly increased for 8 months; then remained stationary till present time: ill 4 years.

On admission—abdomen considerably distended; fluctuation distinct; pain in loins, hips, and left side, on deep inspiration; scanty urine; costive bowels. 10th: abdomen painful: now menstruating.

Treatment—M.M. cum M.S.—25th: paracentesis.—26th: Tinct. Opii m. xxv.—28th: Cal. cum Opio et Liq. Opii sed.

Progress—Sept. 17th: distended to the utmost.—25th: only a few ounces of fluid withdrawn, from the compound nature of cysts. Vespere: an immense quantity of fluid escaped from the wound.—26th: better: abdomen distended with air.—28th: sudden rigors; tightness at scrob. cord.; vomiting of glairy fluid; burning sensation at umbilicus; collapse; cold surface; blue extremities; cold sweats; little diarrhœa; but much abdominal tenderness.—9 P.M.: trocar wound gaping and inflamed: pulsatile a thread: sinking.

Sept. 29th: death. No examination could be obtained.

CASE 5.

Mary M—: Mary's Ward, No. 12: admitted Feb. 28th, 1835, under the care of Dr. Ashwell: aged 57: widow: one child 3 years since: catamenia ceased 10 years ago: sallow; dark hair and eyes: had good health till within the last year; occasional leucorrhœa; severe pain in loins and flooding 6 months since (as

much as a quart), which recurred every 3 or 4 weeks: constant draining in the intervals: ill 6 months.

On admission—a large tumour in the left side of the abdomen, extending as high as the ribs: it seems to be divided; the lower part being very, and smaller than the upper, which is more extensive, and very moveable: flooding: difficult micturition; costive bowels; os and cervix uteri healthy.

Treatment—Stimulants, opiates, purgatives, enemata: Croton oil. Infus. Secal. C. o. i. Zinc. Sulph. et Alum. aa ʒi. pro injec.

Progress—Remarkable for the following circumstances:—flooding; leucorrhœa; tumour pressing on the rectum; occasional scybalous discharges, at which time the vomiting was alleviated; incontinence of urine; great pain in the growth; vomiting of apparently fecal matter. There can be little doubt that this was one of those malignant growths of the ovary so well described by Dr. Seymour. The fluctuation was not sufficiently distinct and extensive to allow of the opinion that it was produced by regular dropsical effusion into a schirrous and indolent ovary. The rapidity of the progress, and the extreme suffering, confirm its malignancy.

No examination could be obtained.
Guy's Hospital Reports.

LITERARY INTELLIGENCE.

Dr. Castle's Translation of the Pharmacopœia Londinensis, with Descriptive and Explanatory Notes on the Materia Medica, &c. is nearly ready for publication.

PARAMORPHIA.—A new substance, extracted from opium by Pelletier. It is obtained by adding lime-water to an aqueous solution of opium, washing the precipitate, drying it, and then dissolving it by boiling alcohol. Nearly all the morphia will remain in the waters with which the precipitate was washed. On evaporating the alcohol, a brown, granular mass will be obtained, which is next to be acted on by ether. This solvent will remove the paramorphia, leaving behind a black, extractive matter. The new principle can be procured from its ethereal solution by evaporation, and then the processes of re-solution and crystallization can be had recourse to, with the view of further purifying it.

ARGILLA DEPURATA.—M. Duerr has employed the argilla depurata (purified alumen), with considerable advantage in the treatment of the dysentery and cholera of children. It may be given without fear in the early stage, when the inflammatory symptoms forbid the use of chalybeate remedies. In order that it may exert a beneficial influence, it must be administered in large doses, from half a drachm to a drachm in the twenty-four hours.—*Hufeland, und E. Osan, Journal des praktischen Heilkunde.*

GUM ACAROIDES.—Dr. de Kay states, that a resin which exudes spontaneously and copiously from the *acarois resinifera* is freely used. The tree grows in the neighbourhood of Botany Bay. The resin is known in commerce by the name of Botany Bay Resin, or Yellow Gum. It is considered to be an agreeable tonic, and is, by the natives of New South Wales, looked upon as a specific in dysentery. It has also proved of advantage in dyspepsia, hysteria, cholera, diarrhœa, and colica pictonum; its exhibition is contra-indicated, when there are symptoms of inflammation present. It is most generally given in the form of tincture.—*N. Y. Medical and Physical Journal.*

Dr. Sigmond has been elected an Honorary Fellow of the Medical Society of Stockholm, as a tribute of respect for his improvements of the Materia Medica, in the room of the late, celebrated, Professor Geiger of Heidelberg.

M. Des Granges recommends the application of mercurial ointment as an efficacious remedy against chilblains, and the incipient stage of lachrymal tumour. The following is his formula:

R Cerati ʒj
Ung. Hydrarg. ʒj. M.
ft. Ung. *Révue Médicale*
Française, Mars 1837.

Medical Evidence.—During an assault case, the Counsel told the Jury that Medical men were occasionally obliged to use technical expressions in giving evidence, when he was interrupted by Baron Gurney, who said, "except eminent men, who always use the plainest language."

All communications and works for review to be forwarded, (carriage paid) to Dr. RYAN, 4, Charlotte-street, Bloomsbury-square.

London Medical and Surgical Journal.

NOTES OF LECTURES ON PHYSIOLOGY.

BY DR. FLETCHER.

*Delivered in the Argyll Square School of
Medicine, Edinburgh.*

No. XXIII.

GENERAL OBSERVATIONS.

Utility of Physiology to the Medical Man and Mankind in General—Miserable State of Medicine destitute of Theory—Absurd Fancies of Former Ages—Revolted Remedies of Savage Countries—Former degraded State of Medicine—Grimaces of Mesmer—Metallic Tractors of Perkins—Fanatical Intercessions of Hohenloe—Mystic Bottles of St. John Long—Treatment of Epilepsy by Spitting—The Human Heart eaten as a Remedy—Powder of the Skulls of Suicides—Potations of Urine, Semen, the Menstrual Fluid, and the Blood of Gladiators—Dung, Testicles, Penes, and the Scurf from Horses' Legs eaten as Remedies—Dried Weazles swallowed—Stercoraceous Cure for Diseases in Tartary—Contrivances to frighten away Evil Spirits—Savage Customs at Labrador—Drawing Teeth and Amputating Fingers in the Sandwich and Friendly Islands—Deficiency of Medical Students in Physiology—Disinclination to its Study—Disastrous Effect on their Subsequent Authorship—Hollow and Absurd Physiological Theories—Observations on Dr. Mason Good's "Study of Medicine"—Necessity of Clear and Consistent Ideas and precise Language in Medical Authors—Best Means of Studying Physiology—Use and Abuse of Experiments on Living Animals—Precept of Abernethy—Advantage of Studying Physiology on our own Persons—Analytic and Synthetical Methods—Difference between a Physiologist and a Canicide—Best Subject for Analysis—General Contempt for the Literature of Physiology—Inconsistent
No. 7.

Conduct of Declaimers against it—Contributions to the Advancement of Science—Discoveries of Modern Philosophers—Rapid Progress of Knowledge—False Charge of Irreligion brought against Physiology—Atheism and Deism really result from Ignorance—Absurdity of the contrary Doctrine—Plato on God's Epistle to Mankind—Testimonies of Cicero, Seneca, Pliny, Galen, and Paley.

So much, then, for the arguments commonly adduced against cultivating the study of the Theory of Medicine, as being useless, either to the medical man or to the man of the world. But an additional and very forcible argument on the opposite side may be collected from a consideration of what would necessarily become the condition of Medicine, if theory were abandoned, or, in other words, of what has always been its condition in those countries in which theory has either never had a beginning, or has afterwards, from political degradation, been neglected, and of what is still its condition with those persons among us who, either from weakness of intellect or defect of education, from infancy or from old age, are incapable of theorising. It is idle to say, "We will not look at causes; we will regard effects alone." The human mind, "that mind of man, that godlike spring of action," must be continually employed in some way or other. The most abject savage, the gibbering idiot, the untutored clown, the puling infant, the decrepit dotard; all must have their minds, such as they are, in some degree engaged; and what they want in reason, they invariably make up in credulity and superstition. In as far then as we desert theory in medicine, it is reasonable to believe we shall become deluded by hallucinations, incomparably worse than the worst into which theory can lead us. It is needless, in support of this position, to go into all the absurd fancies which the

people of former ages, or the savages of modern times, have entertained, and do still entertain, with respect to the causes of diseases, or the idle measures to which they have resorted, and do still resort, in the treatment of them. From this degraded state, the practice of medicine has only very gradually recovered itself in European countries; and recovered it may be said to be, in spite of the grimaces of the Mesmers; the metallic tractors of the Perkinses, the fanatical intercessions of the Hohenloes, and the mystic bottles of the St. John Longs, of which one is still condemned occasionally to hear. But among the barbarous and semi-barbarous people, whom theory has not yet enlightened, the opinions still prevalent respecting the causes of diseases, are as wild as ever; and the practices still had recourse to in cases of sickness, are equally idle and absurd, not to say cruel and revolting. We learn from one of Plautus's plays, that it was the custom in the ruder days of ancient times, for all the bystanders to spit upon a person affected with epilepsy, as a means of restoring him; whence one of the numerous names of that disease was the *morbus in sputandus*. The following are some of the other remedies sometimes resorted to in these cases by the ancient empirical physicians. They made the wretched patient regale himself on slices of the human heart, or on the powder of the skulls of suicides, washed down with potations of dung, urine, semen, menstrual fluid, or hot blood from the wounds of slaughtered gladiators, or on the testicles and penes of various animals, the scurf from horses' legs, or dried weazles devoured whole, together with numerous other delicacies which exceed in horror "the grease that's sweated from the murderer's gibbet," or any other execrable ingredient of Macbeth's cauldron. These are worse, ten thousand times worse than the worst enormities to which errors in theory ever gave rise; and many of these, and others as bad and worse than these, are still habitually resorted to by the savages of modern times. Thus the Plautian remedy for epilepsy, is still in full vigour among the tribes of Columbia river, and other barbarous hordes, in a great variety of diseases; and the dried dung of the Grand Lama is still the chief remedy for all diseases with some of the inhabitants of Tartary, who not only wear it in little boxes hung round their necks, but absolutely eat it, mixed with their food and drink. In order to frighten

away evil spirits, or for some other purpose equally sagacious, it is a prevalent practice with many savage nations to whistle and sing, and roar by the side of the sick, and sometimes to rattle stones in shells, to ring bells, strike symbols, or blow trumpets in their ears. What, in the great majority of diseases, must be the result of such a practice may be easily imagined. But the custom at Labrador of thumping the head on the floor to music, in order to cure the headache, and in the Sandwich and Friendly Islands, of drawing a tooth, or cutting off a finger, as a remedy for diseases in general, are still more singular and shocking. So prevalent are the customs last mentioned that, according to Captain Cook, scarcely an individual is to be found in those islands, with his proper complement of teeth and fingers. Among all the evils which have been so thoughtlessly said to result from theory in medicine, enormities like these cannot fail to be laid to its charge.

I have been thus particular in endeavouring to refute the charge of inutility, if not of an absolutely mischievous tendency, so recklessly laid upon the study of physiology, because I conceive it is to the prejudices thus inconsiderably excited against it, that we must ascribe the comparative lukewarmness with which this branch of medical study is commonly entered upon by students of medicine, and the comparatively inconsiderable progress which they generally make in it. From a prolonged an intimate acquaintance with the more advanced students of medicine in this University, I feel justified in asserting that in no branch of their profession are they generally more deficient than in this, which can only arise, I imagine, from the false views commonly entertained of the scope and tendency of this science; for the science itself is certainly not less interesting than those in which proficiency is much more common; nor are the teachers of it in general less talented or attractive than those who profess the other branches of medical education. Whatever may be the cause of it, however, this imperfect attention paid by students in general to the study of physiology, during the period of their studies, has consequences the most distressing when they subsequently turn authors, as most of them now do turn. It is to this cause we must attribute the host of hollow and absurd theories which, notwithstanding the advance which this science is unquestion-

ably making, one is still frequently condemned to hear handed about by medical men, if not trusted to and acted upon. Many of these are particularly examined in the Lectures; but I cannot avoid alluding here, in proof of my assertion, to those advanced in the ponderous and pompous tomes, recently published by a learned Nosologist, whose pretensions are such as to render his errors and deficiencies less pardonable, and at the same time more pernicious than those of others. Of this work almost every page is defaced under the misnomer of theories, with strings of "words, words, words," heedlessly looped together, always without any general bearing, frequently without any meaning at all, and sometimes, when any meaning can be detected, in direct opposition to each other. The mere fact that this work has attained, I will not say popularity, but toleration among us, is abundant evidence that the theory of medicine is not, even at this advanced period, generally cultivated with that attention, nor its doctrines generally delivered with that precision which they deserve, and it is obvious that as the want of mature study of the subject seems to result from the degree of distrust which students frequently entertain of theory in medicine, so the want of clear and consistent ideas and precise language, when they become authors, must have the effect of perpetuating this distrust, and thus of materially obstructing, if not of entirely stopping up, every avenue to improvement.

Having thus attempted to demonstrate that the study of physiology, imperfect as it is, has already done much for the profession, both as an art and a science, that its imperfect state is an argument for rather than against the study of it; that we may reasonably expect that a proficiency in it, will become every day more and more essential to the success of a medical man; and that such a proficiency is to be obtained, not by the desultory and isolated contemplation of a few phenomena, as they now and then present themselves, and as we now and then find ourselves in the humour to decant upon their causes; but by a continued plan of study, to be steadily prosecuted through all the principal phenomena of health and disease; it remains for me only to mention what plan I consider best adapted to the end in view; in other words, what plan I adopt in these lectures. Previously to doing this, however, I shall subjoin a few general hints

on the best means of privately prosecuting these studies and on the disposition of mind with which they should be uniformly conducted.

Far be it from me to discourage the method of studying physiology and pathology by experiments. I am abundantly well aware how much this plan of interrogating nature has done, in modern times, for every branch of physical science; but I am equally well aware, that these advantages have been in general overrated; at any rate that student who pursues that plan begin at the wrong end, being engaged in experimenting on animals, in hopes of finding out something or other on which to found some new and surprising doctrine, while they take no manner of notice of the great number of things continually going on in their own bodies, of the rationale of which they are as ignorant as the child unborn. It was a precept which I learned from my first teacher in medicine, the venerable Abernethy, never to forget that I always carried about with me the best subject for observation and experiment; one the most easy to be consulted, since it was quite in my power; and one, the phenomena of which should be the most interesting to me, since it was with similar beings alone that I should in future have any immediate concern. This precept I have never lost sight of; and I beg now most earnestly to recommend it to my hearers. If from time of rising to that of betaking ourselves to rest, we accustomed ourselves (during both health and sickness) to endeavour rationally to explain every thing which took place in our bodies, and to assign a consistent cause for every motion and sensation within us, we should have comparatively little to learn, I apprehend, from experiments on dumb animals; and should be secured, in a great measure, from being deceived by those hollow explanations which are sometimes offered of the phenomena in question. Let those, then, who are so prone to indulge in the prevailing cant of the great superiority of the analytical system of science (as cultivated by the moderns) over the synthetical system (as adopted by the ancients) continually keep in mind, that a physiologist and a canicide are not synonymous terms; that the best subject for analysis is themselves, and the most useful contemplation is that which relates to the most common processes; and that till they understand all which can be readily understood, with a little reflection, about

themselves, and know the rationalia of all familiar phenomena, it is preposterous to pore over the penetralia of other animals, in search of things which are recondite, and comparatively useless.

Another thing likewise to be done, in order that the young medical theorist may not betake himself, as many do, to motiveless and tiresome experimenting, is to study with attention, not only the notions at present generally entertained of the several subjects of his investigations, but also those which have been held respecting them at any previous time, although they may since have been abandoned. This, I know, is considered by many to be a very superfluous labour, one of the best physiologists of the present day being unfortunately a good deal addicted to decrying any study, in prosecuting this science, except that of the animal body; and there is consequently a remarkable tendency to the adumque observable in the noses of most people as often as the literature of medical theory is mentioned; for most people think only as their pastors and masters direct them. It is, however, a little inconsistent with the professed principles of the said declaimers against medical literature, that they are still incessantly writing themselves; since, if people universally followed their advice, *their* books as well as those of their predecessors would be entirely useless. Fortunately, however, for them and for us, people in general are not quite so senseless. Before they can experiment with advantage themselves, they feel, or ought to feel, that they must know what previous experimenters have done; and before they can draw satisfactory conclusions from their experiments, they feel, or ought to feel, that they must know what conclusions have been drawn before; and for what reason these conclusions are either still countenanced, or have been abandoned.

Furnished, in this way, with all the light which can be obtained by continued reflection on every-day occurrences, and by diligent study of the opinions successively entertained on every point connected with the subject, the student of physiology will proceed to consult nature experimentally with some prospect of advantage, since his experiments will be instituted with some definite design; and his conclusions from them will be tempered and corrected by a knowledge of the past and present state of science, not only with regard to the subject immediately in hand, but also to that of all

others directly or indirectly connected with it. If so furnished, moreover, he will not give himself more credit for what he may perhaps contribute to the advancement of science than he deserves. For the most part, the discoveries of modern philosophers are to be attributed, not so much to themselves, as to the age in which they live. So many are the heads and hands at present employed in advancing science, and so rapid are the strides which it is now every where making, that what one man does not hit upon to-day, another is almost sure to hit upon to-morrow. The most important discoveries are, as it were, forced upon the discoverers of them; and in making them, we only add perhaps an inconsiderable link to a long chain already all but perfect, and which any body else might have added as well as we. The general diffusion of science is as unfavourable to vast reputations, as the general diffusion of morality is to vast virtues, or the general diffusion of wealth to vast fortunes. Where all are well informed, no one can (to any surprising extent) surpass his neighbours; and it is only in ages of general darkness that we meet with an Aristotle, as it is only in ages of general vice and debauchery that we meet with a Cato, and of general want and wretchedness with a Lucullus.

But precipitancy, ignorance, and self-conceit are not the worst faults from which perhaps the students of the theory of medicine require to be defended. The study is said also sometimes to give rise to irreligion. That ignorance should occasionally make men atheists or deists, is sufficiently intelligible; but how the continued study of the sublimest of God's works should ever have led, either to atheism, or to a disbelief in revelation, I can no more conceive, than how the contemplation of a beautiful and intricate piece of mechanism should lead either to a denial of the existence of the mechanic, or to a disbelief in his account of the purposes and destinations of his contrivance. It was remarked by the sublime Plato,—“The world is God's epistle to mankind;” and it is sufficiently well known that Cicero, in his work “*De Naturâ Deorum*,” when he wishes to prove the existence of a Supreme Cause, dwells more upon the fabric and functions of the human body than on any thing else. Seneca and Pliny were almost as much preachers as philosophers. Galen's work, “*De Usu Partium*,” may be regarded almost as a prose hymn to the Creator of the universe; and the excel-

lent Paley (to omit numerous other authors) in his "Natural Theology," draws his strongest proofs of the existence, the wisdom, and the goodness of God from the facts afforded by physiology. It is perhaps out of my province to dwell more particularly on this subject, but I cannot avoid cautioning students, and young students in particular, to receive with the utmost reserve all those flippant and irreverent remarks, sometimes unhappily met with in physiological works, the tendency of which is to shake their faith in truths which it must distress them to doubt, and wither them to disbelieve. A want of religion is not a mark of profound philosophy; for the greatest philosophers have bowed before that Being, in whose sight their utmost wisdom is foolishness. Nor is it a mark of extensive erudition; for the most eminent scholars have left behind them imperishable monuments of their devotion:—nor of superior spirit; for the greatest heroes have been as renowned for religion as for courage:—nor of high fashion; for persons of the most exalted rank have been no less conspicuous most unaffected piety. But it is a mark,—and, as far as my experience goes, a never-failing one,—of a half-witted and half-educated, dastardly, and vulgar reptile; not a daring hero (as he perhaps tries to persuade himself), since his wretchedly contracted views of things render him unconscious of what he braves; and the furthest possible from a well-bred gentleman; since good manners would have taught him to treat with deference even the errors of the great and good, of all ages and of all nations.

AN ADDRESS

DELIVERED TO THE MEMBERS OF THE

WORCESTERSHIRE

NATURAL HISTORY SOCIETY,

ON THE OPENING OF THE

WORCESTERSHIRE MUSEUM,

SEPTEMBER 13, 1836.

BY CHARLES HASTINGS, M.D. F.G.S.

It has certainly on many occasions, in the course of my life, fallen to my lot to be placed in situations of responsibility, in which I have felt doubtful of my

power to do justice to the task I had undertaken; but at no former time that I can call to mind has this impression been so strong as at the present moment.

The occasion on which we meet is so novel, so important, and so striking, that it is calculated to call forth sentiments more exalted than I can hope to express, and, therefore, this responsible duty ought to have been entrusted to some veteran labourer in the field of knowledge, who might have elevated your minds to higher and nobler aspirations than I can hope to produce in them. The dedication of this temple to science—this splendid edifice, which will be a monument to future ages of the zealous desire of the present generation to advance the progress of useful knowledge—should have been undertaken by some votary more capable of making a suitable offering on its altar. But I need not detain you to relate the circumstances which led to the disappointment of the expectation I had entertained, that this address would have emanated from one whose habits and pursuits render him more equal to the task than myself.

I shall, therefore, at once proceed to the discharge of my allotted duty; and in order to place more clearly before you what has suggested itself to me, I will arrange my observations under the three following heads:—

1st. I will endeavour to show the good results that are likely to ensue from well-regulated societies formed for the cultivation of knowledge, and more especially from the establishment of the Worcestershire Natural History Society.

2d. I will make some remarks on the advantages and pleasures of Natural History; and

3d. I will succinctly trace the progress of natural History from its earliest rude and barren state to its present advanced and promising condition, by shortly laying before you some accounts of the labours of its most successful cultivators.

The claims of societies of this kind generally to public support are so well explained in a paragraph quoted in the Report of your Council last year, that I am induced to repeat it on this occasion. In speaking of an isolated cultivator of science, it is observed, "He may, indeed, gather recreation and delight in limiting his contemplations to the simple objects which a rural walk affords to him. He may be content to admire a few detached ornaments of the temple, without de-

siring to understand the extent and harmonious construction of the building itself. But if he desire to quit this humble path of inquiry for another more elevated, if he wish to generalise his ideas and compare his observations with those of others,—he is no longer, as in the former case, dependent on his own resources; he must associate with those of similar pursuits and studies with himself; he must learn to distinguish that which is known from that which is unknown, and this can only be done by a reciprocal communication of knowledge. Hence the origin of all societies. The value of such associations is greater than at first sight it appears to be; for besides those advantages just mentioned there is another, without which the most gifted minds would probably remain inert and inactive. Intercourse with congenial spirits excites that noble and generous emulation which has been the impelling principle of some of the greatest of men, and it will ever prompt them to the exertion of energies never before called into action. Many, therefore, of the best interests of science are involved in the construction of these societies; they exercise in various ways an important influence upon the advancement of human knowledge, and they consequently demand the serious consideration of those who feel interested in its extension." There is also in the peculiar circumstances of England an additional motive for the formation of societies for the advancement of the study of nature. There is no civilized country in Europe of which the government has shown so great an indifference with respect to the progress of science as that of Great Britain. Even in far less civilized and enlightened ages than the present, patronage was extended to science by the sovereigns of Europe; but it is a fact much to be regretted, that in this country, where, owing to our commercial and maritime affairs being on so extensive and vast a scale, its cultivation is of more importance than in any other European state, our Government has been supine on this subject, and little national encouragement has been given to those who have made important discoveries in it. Of all the countries of Europe, France is undoubtedly the one in which the scientific establishments have been conducted on the most enlightened and liberal principles, and in which science is most successfully cultivated. This high distinction she owes to the formation of the

Institute at the close of the last century, and to which upwards of £100,000 is annually paid by the French Government. Owing to this circumstance many members of the Institute are in opulent circumstances, and can, without anxiety and in calm seclusion, pursue their scientific inquiries; or, if they desire to be distinguished in public life, all the honours of the State are open to philosophers and literary characters. The sage and the hero deliberate in the same cabinet; they are associated among the privy councillors of the king; they sit together in her house of peers and in her chamber of deputies; they bear the same titles, they are decorated with the same orders; and the arm and the mind of the nation are thus indissolubly united for its glory and for its defence. This supineness of the Government of England makes it the more important that means should be adopted by which the patronage and support of the wealthy, the intelligent, and the enlightened community constituting this great country should be as much as possible extended to the advancement of knowledge; so that the genius and perseverance of Englishmen in the investigation of truth may be crowned with success, even without those extraneous aids afforded in other countries.

There is nothing that would tend more to bring about this desirable result than a general organization of scientific societies throughout the kingdom, which would have the effect of making the study of Nature more prevalent among the educated classes of society, and every where men of wealth and title might then be found to be active cultivators of popular and practical science. "I have often wondered," says Sir Humphrey Davy, in his 'Consolations in Travel,' "that men of fortune and of rank do not apply themselves more to philosophical pursuits; they offer a delightful and enviable road to distinction, one founded upon the benefits and blessings conferred upon our fellow-creatures; they do not supply the same sources of temporary popularity as successes in the senate or at the bar, but the glory resulting from them is permanent, and independent of vulgar taste or caprice. In looking back to the history of the last five reigns in England we find Boyles, Cavendishes, and Howards, who rendered these great names more illustrious by scientific honours; but we may in vain search the aristocracy now for philosophers, and there are few

persons who pursue science with true dignity; it is followed more as connected with objects of profit than those of fame, and there are fifty persons who take out patents for supposed inventions, for one who makes a real discovery."

Such were the sentiments of this distinguished English philosopher, as expressed only a few years since; and the decline of science in England was made the subject of a powerful and eloquent appeal to the public by Mr. Babbage shortly afterwards. Since that time a great national society has been formed,—The British Association for the Advancement of Science,—in imitation of similar institutions on the continent, and not only has it been instrumental in congregating together, every year since 1832, all the celebrated naturalists and philosophers of this country, but also several hundred persons of rank and talent have assembled on these occasions to testify their love for science, and their desire that it should be zealously prosecuted in this country.

The splendour of the late meeting at Bristol has greatly added to the general interest taken in this great national association, and has strengthened the conviction of reflecting men, that it is eminently calculated to diffuse a general taste for knowledge, and to assist in its advancement. There is another and a very important advantage that arises from societies of this nature. The congregating together of men of various classes and opinions, all desirous to promote the common interest, cements a friendly intercourse at once beautiful and useful. Asperities are rubbed off; a valuable example of union and social kindness is set; strangers see men of high influence and station, whom they know to be strongly opposed in other relations of life, acting together with amenity for a general benefit, and this example is not lost upon the community at large. It was well said by the noble chairman of the British Association, the Marquis of Northampton, "I trust that Bristol will follow the example of other places which this Association has visited, and that for this week at least, all sectarian feelings will die away, and the hideous forms of political and religious animosity will be banished, for it is not by hating our fellow-men that we show either our patriotism or our religion." In furtherance of the design of bringing about a general voluntary combination of the educated classes in this country for scientific purposes, nothing seems more happy than the sug-

gestion for the formation of County Natural History Societies, whose members shall be engaged in investigating all the facts presented by Nature in their several districts, and in collecting together in museums those curiosities which might otherwise continue to be unnoticed. For this suggestion the world is indebted to Dr. Conolly, and I am proud to add, that the county of Worcestershire has taken the lead in adopting it. It is now three years since the Worcestershire Natural History Society was instituted, and it has received during that period most encouraging support from all classes of the inhabitants. In order to secure the particular investigation of the several branches of the natural history of the county, it was determined at the commencement of the undertaking to divide the Society into sections; and in furtherance of these views, committees have been appointed each year on Statistics, Zoology, Botany, Geology, Mineralogy, and Meteorology. The labours of these committees have been very useful in collecting together valuable information, which otherwise would not have been brought forward. The accession of new facts must, indeed, mainly depend upon the zeal and energy with which these sections exert themselves for the advancement of the objects for which they are appointed; and on the statistical committee in particular a heavy weight of responsibility rests, as upon its members will devolve the duty of carrying into effect the recommendation contained in the report of the Council, delivered to the anniversary meeting of the Society held in 1835, relative to the publication of an improved history of Worcestershire, which should have an especial view to its natural history. The Council advised that, for the convenience of purchasers, and also that the labour of the undertaking might not at once prove too onerous, the work should come out in parts. The consideration of this proposition has engaged the attention of the statistical committee during the past year, and it is truly satisfactory to find that, under their superintendence, the contemplated publication, which, if properly conducted, will doubtless prove of great value, will shortly be commenced, as two of the members of that committee have already been requested to draw up a full account of the statistical and general history of the parish of Great Whitley, and the task is so far completed, that it now only waits the necessary time for passing

through the press to be submitted to the public.

There is every reason to believe that the able manner in which the local history of that parish has been executed, will secure for it an extensive circulation throughout this intelligent county; in which event the Society will be justified in proceeding in their praiseworthy undertaking, and will gradually collect together a correct history of each parish in the county, so as to present an invaluable body of information, which may prove of the utmost importance to the traveller, the antiquary, the man of science, and the naturalist. The committee invite the ministers of religion, magistrates, gentlemen residing on their estates, in short all persons to assist them in collecting local information for this object; as there are few, if any persons in existence, so devoid of observation and curiosity, as to be incapable of communicating some knowledge of the productions of the situations in which they are placed.

The different sections, then, of the Society to which I have just adverted, are assiduously employed in endeavouring to advance our knowledge of the productions of the county; but we must remember that diffusion and advancement are two processes different in their nature, and each may exist without the other. It was found therefore very desirable that means should be taken by this Society, not only to advance the knowledge of the natural history of Worcestershire by the labours of those who were already initiated into science, but also to diffuse a taste for this study throughout all classes of the community. For this purpose lectures have been instituted and three courses of them delivered. They have been principally confined to natural history, and the effect has been that crowded audiences have been attracted to the lecture-room, and it may fairly be presumed that the talent and eloquence of those who have drawn together so many of the enlightened, wealthy, and influential inhabitants of this city and neighbourhood have had the effect of increasing the estimation in which these pursuits are held by the public, and of diffusing more generally a knowledge of them among the mass of our countrymen.

But after all, whatever exertions may be made by this Society to diffuse a knowledge of natural science by lectures, it is manifest that without books to which

the student can refer, the knowledge thus acquired will be comparatively superficial. It is a matter of regret that books of natural history do not so often find their way into our public libraries as might be wished, particularly the 'Transactions of the Linnean and Geological Societies.' It therefore became an object of great moment to establish a library in connexion with the Society, which should be principally devoted to natural history. The funds of our Society, it is to be regretted, have not hitherto been sufficient to enable us to purchase many of the valuable and interesting works on those subjects, which are now daily issuing from the press; but the liberality of our supporters has done much in this respect, and it is hoped that, ere long, some arrangement may be made, by which purchases may be annually effected; and these, combined with the donations, which may still be contributed by those who feel interested in the diffusion of the best kind of knowledge, will, before many years pass away, enable the Society to afford to its members reference to a valuable collection of books.

But no object which has engaged the attention of this Society is more important or more calculated to secure the patronage of an enlightened public than the formation of a museum, in which will be collected specimens of the productions of the county and illustrations of its antiquities, as well as curiosities from foreign countries. Indeed, the original proposer of societies of this nature enumerates among their other advantages that they would tend to concentrate in county museums a great part of the valuable collections already made by scientific individuals, or which would naturally be made in the course of the particular labours of several of the sections. The difficulty which individuals find in becoming even tolerably well acquainted with the geology, botany, and natural history of their own county will thus, in a great measure, be removed; its products and manufactures will become familiar to every eye; and its history and antiquities to every mind.

The progress that has already been made in this part of the labours of the Society, and which has rendered it necessary that the appropriate edifice in which we now meet should be erected to receive our collections, gives rise to the hopes that at no distant day our museum will fully realize the expectations so sanguinely expressed in the foregoing para-

graph. But it must be remembered that a continuance of zeal and energy will be required to prosecute this undertaking; and all those who can lend their aid to it, by devoting some part of their time to its prosecution, will be ranked among its most valued supporters. Moreover, as considerable funds will be required to carry on this desirable work, those wealthy individuals who have not leisure themselves, may render the labours of others more available by giving of their abundance to the benevolent design of increasing intellectual gratification, and of spreading useful knowledge throughout the different orders of the community. Thus all may assist in carrying forward this admirable work—all may be partakers of the credit that will arise from its successful prosecution. The votaries of science should persevere in their efforts to procure a more universal admission of the utility of such societies, for depend upon it, as this great country advances in all true knowledge, in future ages not the least interesting page of local histories will be that which bears the stamp of the upward tendency, which will ever mark the nineteenth century. Upon this effort, upon all these, as upon the efforts of the good to mitigate the evils to which, for reasons only imperfectly known to us, men are subjected in this world, but against which we are not left without resources, I cannot doubt that the great Ruler of all events looks with approbation. By Him to whom "the great globe itself" is exhibited but as a small part of a vast creation, no actions of benevolence pass unregarded, or unapproved, or unassisted.*

It is no doubt the conviction that it is the duty of all to assist in directing the stream of knowledge in the present day, which has induced some of our most learned divines to come forward and recommend by their eloquence the promotion of scientific societies. Amongst these I may mention the Rev. Professor Sedgwick, that most able and highly gifted individual, who now adorns the University of Cambridge, and that college in it which has to boast the names of the two greatest philosophers of any age or country—Bacon and Newton—and whose own name will hereafter be added to a list of worthies unexampled in the annals of science. He has lately been delivering a course of lectures to the

Natural History Society at Norwich, and has, by the display of his great and varied qualities, conducted in a high degree to the intellectual and spiritual improvement of that city. He excited the admiration of all who heard him on that occasion by the depth of research shown in demonstrating the interior anatomy of the earth, by sportive wit, by copiousness of illustration, by clearness of description, and above all, by eloquent piety, which, surrounding as it were with a sacred halo the brow of philosophy, bids her at every advance on the path of discovery, trace with reverence and love the hand of an all-wise and beneficent Creator.

The venerable Archdeacon Butler too, now Bishop of Lichfield and Coventry, has been one of the most active supporters of the Shropshire Natural History Society, and in an eloquent and powerful address delivered by him before the members, which is well calculated to increase the high reputation he had previously acquired as a distinguished scholar, enforces upon them the obvious truth that it will never be found that real science is at variance with scriptural knowledge. It may help us to a better and clearer interpretation of those truths which are recorded in scripture, but never will it impugn the sacred oracles, or promote the cause of irreligion or infidelity. If it enlarges our views of this wonderful creation, if it enables us more clearly to understand the mechanism of the world we live in, and the admirable contrivances for the preservation of the creatures which inhabit it, and the unerring laws by which the worlds around us are moved and governed, and retained in their several orbits, or in their dependent systems, it can only lead us to contemplate with more reverential awe the inconceivable power and majesty of that Infinite and Almighty Being who called them into existence by his single fiat, "who spake the word and they were made, who commanded and it stood fast."

It is impossible to contemplate the efforts thus making, by these illustrious individuals, in support of institutions like our own, established for the improvement of mankind, without feeling the mind elevated with an extraordinary hope, and I might almost say a lively faith, in the success of those grand efforts which are now making for the advancement of sound knowledge.

2. In proceeding to the second division

* See Dr. Conolly's Lecture to the Mechanics' Institute at Leicester.

of my subject, in which I have proposed to bring before you a brief sketch of the advantages and pleasures of Natural History, I may in the first place remark that we happily live in an age when something like a just estimate is formed of the value of the study of nature. "Time was when in this country," (as is remarked by a writer in the *Edinburgh Review*), "even enlightened men were to be found who regarded Natural History as a humble department of knowledge, destined for the exercise of the inferior orders of intellect. The mathematician and the natural philosopher assumed to themselves the highest locality in the temple of science, and almost expelled the collector and the classifier from its precincts. Presuming that magnitude and distance ennobled material objects, and invested with sublimity the laws by which they are governed, and taking it for granted that the imponderable and invisible agents of nature presented finer objects of research than the grosser elements which we can taste, and touch, and accumulate, they long looked down upon the humble and pious naturalist as but a degree superior to the functionary of a bear-garden or the master of ceremonies to a cage of tigers." In the pride of their hearts such men forgot that much of man's comfort and happiness in this life depends upon a correct knowledge of the objects by which he is surrounded, and upon an adaptation of these to his physical wants and necessities. As a mere utilitarian principle therefore, unconnected with those higher feelings and sympathies which lead the student of Nature from the creature to the Creator, this pursuit comes recommended to us as closely connected with questions affecting the health, the longevity, and the daily comforts of the community.

(To be continued.)

A PRACTICAL VIEW
OF
LITHOTRITY:
WITH REMARKS ON
THE LATERAL OPERATION OF
LITHOTOMY.

BY MR. ASTON KEY.

The merits, the dangers, and the difficulties of Lithotrity are not yet so justly

appreciated by the profession as to render an examination of them either unnecessary or uninteresting. The former are magnified by its friends and advocates: the latter, by its enemies. The object of this paper shall be, to exhibit, in its proper light, the advantage which this operation holds out; while the dangers to which it exposes the patient shall be fairly stated and impartially canvassed.

Lithotrity is, in some respects, peculiarly unfortunate. It is an art that has done much, and promises more, toward the alleviation of human suffering; and is creditable alike to those who first discovered its practicability, and to those who have advanced it. But it has suffered, I had almost said, equally from its friends and from its opponents. That it should meet with enemies who would seize every opportunity of decrying it, is what a very little acquaintance with human nature, or with the progress of discovery generally, would lead one to expect. Some would endeavour to check its advances, from a dislike of innovation: others would distrust and doubt its merits, from the circumstances of its being an exclusive art, and not practised by the general surgeon. There are others, again, who would dislike to see the operation of lithotomy superseded, from less worthy motives: and there is yet another class of persons; who, with honest intentions, but with lack of knowledge and judgment, declaim loudly against the operation, as unsuccessful and unsafe. This kind of opposition lithotrity has met with in abundance. The question for the dispassionate observer to answer, is, Whether this has not been owing rather to the exaggerated reports of its merits by its professors and its advocates, than to the active hostility of those who doubt its pretensions.

In this country, at least, it will not be maintained that lithotrity has not met with the encouragement it deserved, both from the profession and the public. The latter was led to believe, that a painless, a certain and safe operation for the removal of one of the most afflicting maladies was about to be introduced; and, with this impression, those who have laboured under the disease flocked to the lithotritist, to save them from the horrors of the knife. The majority of the profession gave to it the support which it seemed to deserve—some to the verge of credulity, believing it to be altogether free from danger: others, with more discretion, regarding it as an operation that might, in many cases, avert the danger of

Lithotomy. Whatever may now be the estimate of the value of lithotripsy, its first introduction was hailed generally as a valuable acquisition to surgery: and if its credit has in some degree declined, and its merits appear diminished, in the eyes of English surgeons, it is due to its own extravagant pretensions, and to a presumptuous and ill-judged competition with lithotomy, which, in a fair examination, it will hardly be found to maintain.

It is an invidious and a painful task to advert to the want of candour justly complained of in those who have exclusively practised the art. To this cause is to be attributed much of the distrust of lithotripsy that many well-informed persons express. There has been, it cannot be denied by its friends, a blamable suppression of the dangers of the operation, and a withholding from the profession of unsuccessful and fatal cases; the patrons of the art having assumed the characters rather of strenuous partisans, than scientific cultivators of a useful branch of surgery. It would appear, that, in too many instances, the interests of lithotripsy have been sacrificed to those of its professors. To forward the ends of the practitioners of the art, it has been unwisely stated to possess advantages over lithotomy to which it has no claim. Lithotripsy neither needs nor deserves such false support: it has merits of its own, by which it may fairly be tested; and should shun competition with an operation that has been sanctioned by the experience of years. Before a judgment can be formed of the comparative success of the two operations, the exclusive advocates of lithotripsy must state the results of their cases, with as much candour and fairness as the English lithotomists have already evinced.

At present, there is but little chance of obtaining such a statement of the results of cases, as would enable us to draw a tolerably correct inference as to its comparative success. In France, the question has assumed the shape of a contest but little creditable to those engaged in it; but out of which, perhaps, something like the truth may hereafter be obtained. One party places lithotripsy in a light too favourable for an unprejudiced person to give credence to their statements: the other, with equal vehemence, is opposed to the operation, and denounces it as a highly dangerous and unsuccessful branch of surgery. I have attempted in vain to reconcile the conflicting statements of Messrs. Velpeau and Civiale of the suc-

cess of the operation; and can only suppose that the latter, when he enumerates 286 patients cured out of 344, employs the word "cured" in a different sense from that in which we understand it. That so large a proportion of cases of lithotripsy should be cured, is a statement that surely carries with it its own refutation. M. Velpeau's reduction of this large number to 130 probably brings it nearer the truth.

It is needless for me to enter into the controversy between these two surgeons, as to a matter of fact. The data are not sufficiently explicit to enable me to solve the question, whether M. Civiale has overstated his success, or M. Velpeau has been led to take too unfavourable a view of M. Civiale's table of results: and even if I could arrive at the truth, it would be foreign to my purpose. It is not my intention to be a partisan of either side of the controversy; nor is it my object to take up lithotripsy as opposed to lithotomy. The question has, indeed, assumed this aspect. It has grown into an unbecoming contest between the lithotriptist and the lithotomist; as if the two operations were wholly opposed to one another, and could not be made available, each in its own and proper sphere.

If it be intended, by the exclusive advocates and practitioners of lithotripsy, to maintain, that, indiscriminately applied to all cases of stone in the bladder, it is a less painful, more safe, and more successful operation than lithotomy, I must be allowed to express my doubt. If it be proposed to introduce lithotripsy to the entire exclusion of the knife, as an operation that holds out a better prospect to the sufferer under stone for the cure of his malady, I am disposed to think that society would suffer by the exchange: or if, in support of their exclusive views, the advocates of lithotripsy claim for their operation a superiority of success, as compared with the results of lithotomy, I am prepared to say, and to prove, that the history of English lithotomy furnishes records of success that leaves lithotripsy far behind.

To show that lithotripsy is neither so universally successful, nor so exclusively applicable as might be inferred, I shall briefly detail the cases that have passed under my observation, occurring in the practice of the two most able lithotriptists of the day. In each of these cases I was consulted.—Others, strongly militating against the exclusive use of the operation, have come to my knowledge; but which,

as not occurring in my own practice, I forbear to mention.

Case 1.—In 1829, an Irish gentleman, Mr. H—, about 64 years of age, arrived in this country from Paris, to obtain professional advice for a vesical disorder. I learnt that he had undergone the operation of lithotritry under M. Civiale, about six weeks previously; and that the operation had been followed by acute inflammation of the bladder, for which M. Amusat was consulted. As soon as the cystitis subsided, he came over to this country, labouring under symptoms of stone in the bladder, which, in severity, I have only on one occasion seen exceeded. The desire to void urine was nearly incessant, and the attempt excruciating, and often unsuccessful. He lingered out a miserable existence for a few weeks, receiving such relief as medicine could afford. On passing a flexible catheter to relieve the bladder, I discovered a considerable fragment of stone. Sir Astley Cooper saw this gentleman several times, and considered him beyond the reach of any operation. He died with his sufferings unmitigated.

Case 2.—Mr. E—, between 50 and 60 years of age, had been annoyed for some time with symptoms of disorder, which Mr. Giraud, of Feversham, found to arise from a calculus in the bladder. He came to town, at the request of Mr. Giraud, to consult me. Finding the stone small, I gave him the alternative of the two operations. He preferred lithotritry; and went to a well-known operator, with a note of introduction from me. He underwent the operation; and the stone was broken down at several sittings. Before returning to Feversham, he called upon me, and seemed feverish and ill; and I learnt subsequently, from Mr. Giraud, that he died, with typhoid symptoms, shortly after his return into the country. An abscess was formed in the neck of the bladder, at the base of the prostate gland.

Case 3.—A gentleman from the country, a patient of Mr. Elliott, of Stratford, was discovered to have stone in the bladder, and consulted me respecting it. Finding it to be small, I proposed to break it down; and employed Charrière's drill-instrument for the purpose. Meeting with several obstacles in the attempt, I abandoned it; and he afterwards was placed under the care of the same lithotritist, who broke up, as I was afterwards informed, a small phosphatic calculus. The patient left town with a

very irritable bladder, and suffering much in voiding his urine. I subsequently heard, from Mr. Elliott, that he lived for twelve months, with increasing suffering. On his death, the bladder was discovered to be diseased, and several stones were found in it.

Case 4.—I was desired to visit Mr. N—, aged 70, with Mr. Burrows, surgeon in the city, in order to ascertain if he had a calculus. He had been supposed to labour under stone, but it had not been detected. On sounding him, a calculus was immediately struck by the instrument, and gave me the impression of being large. I explained to him the different operations that might be performed for his relief; and he gave the preference to lithotritry. The same operator met us at the patient's house; and sounded him with care, in order to ascertain the size of the stone, and the condition of the bladder. The former he discovered to be above the ordinary size; and the latter so irritable and contracted, that it would admit of a very small quantity of water only being injected. Under these circumstances, he was thought an unfavourable subject for lithotritry. I therefore removed the stone by the lateral operation, in the presence of the lithotritist and Mr. Burrows. The operation was difficult; and the extraction of the stone not easy, on account of its size, and the enlarged state of the prostate gland. He was convalescent at the end of the second week: and has remained, up to the present time (nearly five years), free from any symptoms of his former disorder.

Case 5.—Admiral C— wrote to me from Exeter, to make some inquiry respecting the operation of lithotomy; as he was suffering from a calculus in the bladder. I replied to his inquiries, and was requested to make the necessary arrangements for cutting him. In the meantime, I was informed, by a friend, that he had placed himself under the care of the same lithotritist, and that the stone had been successfully broken down. Admiral C— left town, but quickly experienced symptoms of a return of his disorder; and one or two fragments were, I believe, again detected, and crushed. He was thus relieved for a time; but experienced a second return of his pains, and died not long after his return into Devon. On examination of his body by a surgeon at Exeter, six or seven calculi were found, formed, as I was told, on the remnants of the original calculus.

Case 6.—About nine years ago I operated on Mr. Saunders, of Tottenham, and removed a lithic-acid calculus. He recovered in a few days after the operation, which was performed with the assistance of Mr. Holt and Mr. Edward Cock. About three years ago he came to me again, with symptoms of stone; and, on sounding him, I discovered a small one, and told him it was small enough to be broken down. He placed himself under the care of the same lithotritist, who crushed a small phosphatic calculus. He left town as soon as he was pronounced cured. Almost immediately after his return home, his pains in making water increased so much, that he said the pain of the stone was as nothing. He became feverish; and his bladder would not retain urine for an hour. I saw him, at the request of his surgeon, Mr. Moon, and thought that he might have some fragments remaining in his bladder. I passed a catheter, but could not detect any. His extreme irritability of bladder prevented any accurate examination by injecting it with warm water. He was averse to this latter measure, from the pain which he had always suffered when it had been formerly done. He died without any mitigation of his symptoms taking place.

Case 7.—In 1834, Dr. Cobb requested me to meet him in consultation respecting a Mr. L—, from Kent, who was suspected to have stone in his bladder. I sounded him, and discovered a stone of a size well adapted for lithotripsy; and as his bladder was not irritable, it was decided that the same lithotritist should operate upon him. The operation was performed at several sittings, and with success. I sounded Mr. L—, at the operator's request, before he left town, and could not discover any particle of stone remaining. Mr. L— also expressed himself quite relieved from his former symptoms. He remains well, October 1836.

Case 8.—I met Mr. Finch of Greenwich at the house of a gentleman nearly eighty years of age, who was much distressed by very urgent symptoms of urinary calculus. I was informed, that a lithotritist had sounded him, and, from his age, and the great irritability of his bladder, declined to operate. His health being good, I saw no objection to lithotomy being performed, notwithstanding the enlargement of his prostate gland, and the irritable state of the mucous lining of his bladder. The operation was per-

formed in the presence of Sir Richard Dobson, Mr. Finch, and Mr. Lawson: it was difficult, on account of the great enlargement of the body and third lobe of the gland; and tedious, from the number of stones, which were found to amount to twenty-seven. His convalescence was retarded by one or two small calculi passing by the wound; and by an abscess of the prostate gland, that burst into the rectum. The symptoms of irritation caused by this subsided; and when I heard of him, he was free from stone symptoms, and was in the enjoyment of good health.

Case 9.—Mr. S—, a patient of Dr. P—, was found to labour under retention of urine, caused by the presence of a small calculus in the bladder. He was lately placed under a lithotritist's care, for the purpose of operation. The stone was crushed, and the patient supposed to be cured. I subsequently met Mr. S—, at the house of Dr. P—, and heard him describe symptoms that indicated the presence of fragments in the bladder. I expressed this opinion to him; and told him to lose no time in applying to a lithotritist. Whether any further attempt was made to relieve him, I did not learn; but he was seized with bleedings from the bladder, which, joined to the irritation that he experienced, in a week or two destroyed him. On a post-mortem examination, several calculi were found in the bladder; and each was discovered, when broken, to be formed on a fragment of the crushed stone. A fungus had also shot forth from the cervix vesicæ, from which the bleeding had taken place.

Case 10.—Mr. C—, a surgeon, was brought to me by Dr. Gordon, in order to ascertain if he had stone in the bladder, as certain symptoms, of which he complained, were considered to depend on the presence of a calculus. On sounding him, I struck a small calculus; and he expressed a desire to undergo the operation of lithotripsy, under the same operator. After one stone was broken down, a second was discovered; and he underwent several operations; the operator telling him that he had crushed several entire calculi. Mr. C— returned home, assured that he was freed from the cause of his disorder. I saw him in three weeks after the last operation, and his bladder still continued to be irritable; but this symptom gradually ceased; and he appeared, when I last saw him, to be altogether freed from his disorder.

Case 11.—Mr. C—, from Yorkshire,

aged sixty, came to town, for the purpose of placing himself under the same lithotritist's hands, for the operation of lithotritry. His bladder was so irritable, that water was with difficulty injected into it. After trying to allay the irritable state of the bladder for six weeks, the operator told him that his was not a case for lithotritry. I was requested to see him. I found him with an exquisitely sensitive bladder, affected with a bloody catarrh: his pulse 120; skin hot; and desire to void urine continual. The operation of lithotomy appeared to promise no success, especially as he had lost a great deal of flesh during his visit to town. I endeavoured to allay the irritation caused by the previous introduction of instruments, and succeeded to a certain extent. On sounding him, I discovered a large stone, and a large prostatic gland. The operation was performed at the end of January, in the presence of Mr. Camplin and two young friends. It was difficult, on account of the stone being closely embraced by the bladder: it measured five inches and a half in its widest circumference. He was slow in recovering; the bladder still remaining irritable, and continuing to secrete a bloody mucus. The wound healed soundly, and his appetite and rest returned; and before he left town, the bladder had, in some degree, lost its extreme irritability, under the use of the *uva ursi*. I heard of him during the past summer, and he was in the enjoyment of good health.

Case 12 occurred in the person of a surgeon in active practice, who was seized with considerable hæmaturia after exercise, and soon complained of symptoms that gradually assumed the character of vesical calculus. On sounding him, a small stone was discovered; and he placed himself under the care of a lithotritist. The stone was crushed after three operations, and he obtained entire relief from his disorder. He now remains well.

Of these twelve patients, three were cured, and three underwent the operation of lithotomy. Of the remaining six who died, one sunk with abscess in the prostate gland soon after the operation; four with protracted sufferings, in consequence of fragments remaining in the bladder; and one with disease of the bladder, brought on or aggravated by the operation; but whether there were fragments left in the case of Mr. S— I was unable to ascertain during life,

and a post mortem inspection was not made.

I believe that no surgeon conversant with lithotomy would expect so unsuccessful a result in these cases if they had been all submitted to the knife. The three patients who could not undergo the operation of lithotritry, but were afterwards compelled to seek relief from the knife, recovered: and it is but reasonable to conclude, that some of the unsuccessful cases would have had a better result, had they been subjected to the same operation.

In the detail of the cases above mentioned, I trust it will not be supposed that I wish to cast any suspicion on the skill of the operators. I believe that all that lithotritry, in the most skilful hand, could effect, was done by the two able operators under whom the cases occurred. It is not the skill of the lithotritists, but the capability of the operation, that it is intended to impugn. I wish to show, that, as an exclusive operation for the removal of stone from the bladder, lithotritry cannot maintain that rank which it has been made to assume; and that if indiscriminately adopted, to the abandonment of lithotomy, it would be found inferior to the latter operation, both in safety and success. The new operation should, on no account, be regarded in the light in which its exclusive advocates would place it—that is, as a substitute for the old; but as a valuable adjunct to it, and as furnishing the surgeon with an additional means of relieving a most alarming and painful disease. If this view be taken of it, it will, I think, be found to be one of the most useful inventions that modern surgery has added to her resources: for in many cases, if selected with judgment, it is not only equally effective with lithotomy, but more safe, and less painful in the performance.

It would be an injustice to an ingenious English surgeon, to make allusion to the infancy of the art, without coupling his name with the earliest attempts made to break down stones in the bladder.* Mr. Elderton has unquestionably the merit of being the first to construct an instrument for the purpose of crushing a calculus, and enabling the patient to discharge it by the urethra. I need not describe the instrument, as an account of it,

* It appears that he constructed this instrument so long ago as 1811.

with a drawing, was published by him in the *Edinburgh Medical and Surgical Journal* for April, in the year 1817. It is not used with a drill, as the earlier French instrument; but acts, on the principle of some of the modern inventions, with a screw and lever.

CASE OF EXTREME DEFORMITY.

To Dr. Ryan.

My dear Sir,—I shall feel obliged by your inserting the following curious case in your very useful and scientific *Journal*. I am, dear Sir, faithfully yours.

JOHN Mc DIVITT.

Canterbury, May 11, 1837.

Sarah Spong, æt. 26, became, twelve years ago, the subject of *morbus coxarius*, for which cupping, leeches, blisters, and other suitable remedies, were had recourse to, with only partial benefit. About twelve months afterwards, she was attacked with an excruciating pain in the head, which was followed by a discharge of sanious pus from the left ear. This completely relieved the pain, which frequently, however, recurred and was always terminated by a similar discharge. On one occasion, immediately consequent upon the extraction of a decayed tooth, a large quantity of pus escaped from the left antrum.

When the patient had suffered for some time in the manner above described, the muscles on the left side of her face became paralysed, and also, partially, those of the *right* upper extremity. The left eye, without any apparent defect, lost the power of vision, and the eyelash together with the hair of the eyebrow, on the same side fell out, and have never since been reproduced. At the same time she was deprived also of speech, and what was very remarkable, she used, regularly at nine o'clock every night to thrust her tongue out of the mouth, and to keep it in that state till five o'clock on the following morning, at which hour it was again withdrawn. After a period of eighteen months, this practice was abruptly discontinued, and her speech was suddenly restored, on the discharge of an unusually large quantity of pus from the left ear. The affected eye has never recovered the power of vision. It looks somewhat atrophied, but is otherwise free from visible defect.

About six years ago she was attacked

with severe pain in the *right* side of the head, which was much relieved by cupping, and altogether removed by the flow from the right ear of a small quantity of pus. During the continuance of the pain, the eyelash and hair of eyebrow on this side also began to fall out, but ceased to do so on its subsidence.

Three years since she had a mild attack of scarlet fever, and, within the last twelve months, one of modified smallpox, having had the vaccine form of the disease when she was four years old. Soon after, the affection of the hip-joint commenced, she menstruated for the first time, and continued to do so regularly for a period of three years, and in an irregular manner for six years longer, since which last time the catamenia have been entirely suppressed.

When the disease had advanced so far as to confine the patient to bed, which she has not left during the last eight years, the affected member began to be flexed upon the abdomen in an oblique manner, and gradually the right limb also became similarly bent. This unnatural position of the limbs has not only been ever since maintained, but the deviation has gone on increasing until, at present, both thighs are thrown towards the right side of the body, so that the knees approach within a few inches of the right axilla. The left thigh, which is the more elevated, passes obliquely across the abdomen, touching the cartilages of the right false ribs. The legs are bent towards the left side, the left lying over the right thigh, and with its heel touching nearly the left ilium, from which, to prevent the effects of pressure, it is separated by two folds of soft linen rag. The ilium, from the distorted position of the limb, is rendered very prominent, and is made to present itself on the anterior surface of the body, on a plane nearly three inches more elevated than the thorax. Over the trochanter is a large caustic issue with a glistening red surface, which, without any irritating application, has kept open for several years. When the discharge from it happens to be less copious than usual, headache, with a sense of fulness of the cerebral vessels, and a general febrile irritation speedily supervene.

The sternum is drawn towards the spine, so as to form, in its upper third, a hollow groove, leading inferiorly to a rounded cup-like cavity, nearly three inches in depth. The ribs on both sides bulge out, yet the lateral diameter of the right side of the thorax is apparently not

more than $2\frac{1}{2}$ inches, that of the left is somewhat more. The spine projects posteriorly to an extent corresponding with the depression of the sternum.

The skin is dry and scaly, and there is extreme emaciation; the upper extremities, however, being somewhat less wasted than the lower. The countenance has a resigned and tranquil look, not expressive even of discomfort, although she still occasionally suffers from headache. The left ear constantly gives issue to a thin sanguineous discharge. The left side of the face, from the total loss of its eyelash and eyebrow, as well as the partially paralyzed state of its muscles, presents a striking contrast with the natural appearance of the right.

She is several times during the day attacked with fits of a very peculiar kind, each paroxysm lasting about five or six minutes. Her arms are suddenly thrown out in an extended form, the fingers being separated from each other, quite straight, and perfectly rigid. The eyelids become affected with a constant tremulous motion, the eyes being for a time fixed in an upward position, then revolving alternately upwards and downwards, and then again outwards and inwards. Her lips and nostrils appear perfectly motionless, but the larynx moves slightly once or twice in the minute. A looking-glass placed near her mouth has not its transparency perceptibly diminished.

Her daily food consists of about the size of a bean of butter, and a tea-spoonful of sugar, together with about two ounces of cocoa containing a very small proportion of milk. Frequently her food, after remaining for a short time apparently in the lower part of the œsophagus, is thrown up, as if there were something obstructing its passage into the stomach. She has, for years past, habituated herself to the use of laudanum, of which she now takes three drachms daily.

She passes usually three small lumps of dark fæces once a week, and her urine, which is strongly alkaline, amounts in the same period to about four ounces, a very small quantity being passed once in every day.

Her pulse is weak, and beats sixty-six strokes in the minute. The heart's action is so feeble as to be scarcely distinguishable. The respiratory murmur is abrupt, the cells appearing to be imperfectly dilated. The mental faculties are unimpaired.

The foregoing account of the case, together with the accompanying drawing, was taken in the beginning of September, 1836. Towards the middle of January last, the patient was attacked with influenza, from which, in a few days, she seemed to recover, but a relapse occurring about a fortnight afterwards, the symptoms presented themselves in a more aggravated form, and the disease, not yielding to the remedies employed, carried her off on the 15th of February. The body was examined on the 17th by Mr. Sankey of Wingham (who had always attended the case) in the presence of the Rev. Charles Oxenden, Mr. Jameson, and myself.

The body was emaciated to an extraordinary degree. The position of the limbs was in no wise altered, nor could they be straightened except by a force sufficient to cause laceration. The ribs, which might be counted as readily as if they were altogether bare, were less transverse than they appear in the drawing. The right side of the thorax projected posteriorly nearly an inch and a half more than the left. The spine was curved backwards, also a little towards the left side. The back presented the scars of two or three bed-sores.

The left hip-joint contained about two drachms of glairy fluid. The head of the femur was still within the acetabulum, the capsular and inter-articular ligaments remaining entire. It was deprived of its cartilaginous covering except for about half an inch around the insertion of the *ligamentum teres*. Its substance was so soft as to be cut readily with the scalpel, and its cells were much enlarged, being filled with a viscid fluid exactly resembling strained honey.

The left eye was less prominent than the right, but otherwise it was healthy. The supra-orbital nerve and artery on the left side (that wanting the eyebrow, &c.) appeared natural. The temporal muscle, on each side, consisted merely of a few fasciculi of pale and almost pulpy fibres.

The convolutions of the brain were large, and the surface appeared unusually vascular. The arachnoid was thickened, and raised up, particularly at the base of the brain, by a layer of semifluid gelatinous matter. The substance of the brain presented, on incision, numerous bloody points. The ventricles contained each a small quantity of limpid serum. The choroid plexus, on each side, was enveloped in gelatinous matter. Of the

septum lucidum only a few shreds remained. The optic nerves were healthy. On the left *crus cerebri* was an oblong patch, about eight lines by five, affected with *ramolissement*, presenting an uneven, slightly hollow surface, of an ash-grey colour mingled with dark lines. The cerebellum and medulla oblongata were healthy, except that the former was, like the cerebrum, unnaturally vascular. There was nothing remarkable in that portion, whether of the brain or membranes, contiguous to the *pars petrosa* of the temporal bone; nor did this, on being sawn through, exhibit any traces of disease, notwithstanding the very profuse suppurative discharge from the left ear. The whole auditory apparatus on this side appeared natural.

The ribs were so soft that their bony portion could be readily divided with a scalpel. On removing their anterior half together with the sternum, and laying back the upper portion of the abdominal muscles, the following arrangement of parts presented itself. The diaphragm was much arched, being pushed up by the liver on the right side, and on the left by the stomach, which, distended with gas, mounted as high as the intercostal space between the fifth and sixth ribs.*

* This is a fact worthy of being borne in mind by those who practise auscultation. When the diaphragm is thus pushed up by the distended stomach, the left side of the thorax inferiorly emits, on percussion, an unnaturally clear sound, the respiratory murmur over the same space is inaudible, and there is produced, by the intermixture of the gaseous and liquid contents of the stomach, a sound exactly resembling the *metallic tinkling* of *Pneumo-thorax*. The absence, in such a case, of this serious disease would not be certainly indicated by the dulness on percussion superiorly, for that might be accounted for by supposing the costal and pulmonary pleurae to adhere above the opening in the lung. In some cases a *plashing* sort of sound is heard, which one might readily mistake for air passing through the semi-liquid contents of a half emptied vomica. An instance of this kind I lately met with in a patient labouring under pleurisy.

In a case of Pericarditis which was under my care in the Kent and Canterbury Hospital some months ago, there was heard, synchronously with the heart's pulsation, a sound resembling the metallic tinkling, and which could be attributed to nothing else than the motion given by the tilting of the heart, through the diaphragm, to the liquid

The heart was placed vertically in the centre of the chest, and separated to the extent of an inch from the thin membranous looking diaphragm, by a straw-coloured fluid, which, contained in the pericardium, was seen distinctly through its attenuated transparent coats. The right lung did not descend by fully three inches as low as the left, and was also separated from the diaphragm by serum, of which a large quantity was contained in both pleural sacs. The heart was somewhat flabby, and rather under the natural size. Its surface, particularly near the root of the aorta, was covered with patches of an albuminous effusion. Its coronary vessels were congested with black blood. The wall of the right ventricle was scarcely thicker than that of the auricle. The left ventricle was affected with concentric hypertrophy, its cavity being very small, and its proper wall measuring seven eighths of an inch in thickness: the septum measured fully $\frac{3}{4}$ of an inch.

The right lung (particularly that portion of it contained in the posteriorly receding part of the thorax) was much compressed, congested, and hepatized, and presented when cut into numerous spots of whitish granular deposit. The bronchial ramifications contained a small quantity of purulent matter. Their lining membrane was continuously of a deep claret colour, which extended upwards to a considerable distance above the bifurcation of the trachea. The bronchial ramifications of the left lung also contained pus, their lining membrane being of a clear red colour. The bronchial glands were much enlarged.

The spine, which has been described as projecting on the outside, and curved slightly towards the left, was found, upon opening the thorax, to be twisted so as to shelve considerably over its right side, thus partially covering that part of this side which projected posteriorly, and which contained, as mentioned above, the more condensed portion of the right lung.

The mesentery was covered with a

and gaseous contents of the distended stomach.

I think it enough merely to mention this source of fallacy in diagnosis, as the positive and negative symptoms, by attention to which it may, in each individual case, be guarded against, must be known to every well-informed practitioner.

thick layer of gelatinous effusion, similar to that found on the surfaces of the brain and heart. The liver, compressed and flattened, so that its largest transverse diameter did not exceed two inches, was almost vertical in its position, the right lobe being inferior, and not extending below the margin of the ribs. Its substance was very firm, as was also that of the spleen. The left kidney appeared larger than the right, both being knobulated and of scirrhus hardness. Their cortical substance had given place to a yellow granular deposit, intermixed with reddish lines. The renal capsules were unusually large, and converted into a thick cartilaginous substance, their sides adhering closely by means of an intervening dense fibrous layer. The other organs presented nothing remarkable.

The spinal marrow unfortunately could not be examined.

The London Medical

AND

Surgical Journal.

Saturday, May 20th, 1837.

THE LONDON HOSPITAL FEE SYSTEM.

It is an important fact, which ought never to be lost sight of, by those who legislate for medical education, that the medical officers of the London Hospitals have long pursued a system of extortion, and levied immense sums of money from the Student, unexampled not only throughout the other, Schools of the British dominions, but unparalleled in the medical Seminaries of all the rest of Europe. The means which they have adopted to bring this system of extortion to its present high degree of perfection, displays as much ingenuity in the Council of the Royal College of Surgeons, as it exhibits a total want of that high moral feeling and honourable line

of conduct for which that body is pre-eminently distinguished. Nothing could be more sagaciously contrived than that the Council men, every one of whom was connected, directly or indirectly, with one of the metropolitan hospitals, should pass by-laws to compel the unfortunate Student to attend one of their recognized institutions for an extended period, before he could be qualified to offer himself as a candidate for one of their valuable diplomas. By this admirable, and no less praiseworthy legislation, the liberal council of Lincoln's Inn Fields were enabled to raise the extortion fee for hospital attendance to its present enormous amount. It is not therefore to be wondered at, that the vultures of Lincoln's Inn Fields should have been seriously alarmed, when the JOINT STOCK COMPANY of Gower Street appended an hospital, to their school, not for any avowed purpose of charity, but for clinical instruction, offering the attendance fee at about half the price of the old rotten establishments. And it is still less surprising, that our hospital *pures* should be now under a still more serious alarm, it being whispered that the Senate of the New Metropolitan University contemplate the destruction of the hospital monopoly, and act in conformity with the opinion so ably advocated by Mr. Lawrence, on the great advantages which the Student derives from attending small hospitals.

However praiseworthy it may have been in the different lecturers of the Gower-street institution, not only to have reduced the fee for attendance at the North London Hospital, but for having given up all the money thus received in order to defray the expenses of the establishment, it was more than could be expected of man, that such a system of generosity and benevolence should go on

for any lengthened period. The *liberal* professors of that institution were satisfied with the *indirect* benefit they would receive from the inducement which the low price of the hospital held out to the student, and the reasonable calculation they made, that the increase in the number of students, along with a large fee for each class, would fully compensate them for their *gratis* labours in the hospital. In making this calculation, however, no allowance was made for the possibility of students entering to the hospital who did not attend any of the classes of the medical school. In consequence, of not less than fifty of those students who were enrolled last season, in order to qualify themselves to become candidates for diplomas, by availing themselves of the small fee of the hospital, though reluctant, and conceiving it unnecessary to submit to some of the soporific discourses, the eminent professors have thus been deprived of that golden tribute of respect they considered due to their merits, and a fair remuneration for their valuable services in the hospital. The JOINT STOCK COMPANY of Gower-street have now, therefore, under their most serious deliberation, to contrive some mode or invent some plan, by which they could secure for the benefit of the physicians and surgeons of their hospital, a fair remunerating price, some kind of percentage, on all such students as attend the North London Hospital, but who do not enter as pupils to any of the classes of the College. A rational plan for accomplishing so desirable an object, and little difficulty could have occurred in fixing an adequate sum as an additional fee to be paid by such students, had not the medical staffs of some other hospitals, more particularly those of the Middlesex and the Westminster, been deliberating on the expediency of reducing their at-

tendance fee, as if they adopt such a measure, of the wisdom of which there cannot be a doubt, the advantages which the North London Hospital has hitherto enjoyed of giving a commodity at half price, will be irretrievably lost. It is, therefore, extremely probable, that the wiseacres of Gower-street will have the sagacity to contrive some other ingenious mode of remuneration. The time, indeed, appears fast approaching, when the whole system of hospital monopoly will be destroyed, and when the medical officers of our public charities must look to some other mode of remuneration than the fraudulent system of extortion which has been so successfully, and which it is lamentable to reflect, has been for so long a period practised on the unfortunate student of medicine.

THE ANATOMIST.

SUTURES OF THE CRANIUM AND FACE.

Frontal suture, commences a little behind the external angular process of the frontal bone, at the upper termination of the great wing of the sphenoid bone, and, inclining backwards, extends across the cranium to the opposite corresponding point, connecting in its course the frontal to the parietal bones.

Lambdoidal suture, commences at the union of the petrous portion of the temporal bone with the parietal and occipital bones, and extending across the posterior part of the cranium to the opposite corresponding point, connects the occipital to the parietal bones.

Sagittal suture, extends from the angle of the occipital bone forwards, connecting in its course the parietal bones and corresponding to the median line; it generally terminates in the coronal suture, but is occasionally prolonged to the nasal bones, dividing the frontal bone.

Squamous suture, corresponds to the semicircular edge of the squamous portion of the temporal bone, and connects it to the great wing of the sphenoid bone, and to the parietal bone.

Additamentum suture lambdoidalis,

extends from the termination of the lambdoidal suture to the foramen lacerum posterius, and unites the mastoid process of the temporal bone to the occipital.

Additamentum suturæ squamosæ, extends nearly horizontally backwards from the posterior termination of the squamous suture to the lambdoidal suture, connecting the upper extremity of the mastoid portion of the temporal bone to the parietal bone.

Sphenoidal suture, extends around the irregular margins of the sphenoid bone connecting it to all the bones of the head, and to the malar, superior maxillary, and palate bones.

Ethmoidal suture, surrounds the ethmoid bone, connecting it to the frontal, nasal, superior maxillary, lachrymal, and palatine bones, and to the vomer.

Transverse suture, connects the bones of the face to those of the head.

Zygomatic suture, corresponds to the junction of the temporal with the malar bone.

ORBITS.

The orbits are two pyramidal cavities, the bases of which look outwards and forwards and their apices in the contrary direction; so that two lines passing through their axis if prolonged posteriorly would decussate at the cella tursica. Each orbit is formed of seven bones, three of which, viz. the frontal, sphenoid and ethmoid, are common to both orbits; the other four, viz. the lachrymal, superior maxillary, malar, and palate bones belonging to the orbit of their corresponding side. The foramina in the base of the orbit are, the supra-orbital, the infra-orbital and the upper orifice of the nasal duct: within the orbit are the optic-foramen, the superior lacerated foramen, the sphenomaxillary fissure and the two internal orbital foramina.

TEMPORAL FOSSA.

Placed on the side of the cranium is bounded by the frontal, sphenoid, parietal and temporal bones, and lodges the temporal muscle.

ZYGOMATIC FOSSA.

Extends from the temporal fossa downwards and is bounded by the zygomatic arch, the superior maxillary bone and the portion of the great wing of the sphenoid bone below its crest.

PTERYGO MAXILLARY FISSURE.

Lies deep in the zygomatic fossa, is

bounded by the pterygoid processes, the tuberosity of the superior maxilla and the nasal process of the palate bone; and communicates with the sphenomaxillary fissure.

ARTICULATIONS.

TEMPORO-MAXILLARY ARTICULATION.

Bony formation. Glenoid cavity of temporal bone and condyle of inferior maxillary bone.

External lateral ligament,—*origin*, zygomatic process and tubercle of temporal bone. *Insertion*, outer side of the neck of condyle of lower jaw.

Internal lateral ligament,—*origin*, spinous eminence of sphenoid bone. *Insertion*, margin of orifice of inferior dental canal.

Stylo-maxillary ligament,—*origin*, styloid process of temporal bone. *Insertion*, angle of inferior maxillary.

Synovial membranes, one is reflected from the cartilaginous surface of zygomatic eminence and glenoid cavity over the superior surface of the fibro-cartilage. The other covers the under surface of the fibro-cartilage and is reflected over the condyle.

Inter-articular, or fibro-cartilage, of an oval figure, thick in its circumference, thin in the centre. Divides the joint into two.

Capsular ligament,—*origin*, zygomatic eminence, and glenoid fissure. *Insertion*, neck of lower jaw.

OCIPITO-ATLANTOID ARTICULATION.

Bony formation, condyles of occipital bone and superior oblique processes of atlas.

Capsular ligament, imperfect.

Synovial membranes, cover the opposed cartilaginous surfaces.

Anterior ligament,—*origin*, anterior edge of foramen magnum. *Insertion*, upper edge of atlas anterior to its oblique processes.

Posterior ligament,—*origin*, posterior edge of foramen magnum.—*Insertion*, upper edge of atlas behind its oblique processes.

OCIPITO-AXOID ARTICULATION.

Moderator, or oblique ligaments,—*origin*, from each side of odontoid process. *Insertion*, inner side of each condyle.

Apparatus ligamentosus,—*origin*, lower part of cuneiform process posterior to

odontoid process. *Insertion*, superior part of transverse ligament of atlas and bodies of second and third vertebrae.

ATLANTO-AXOID ARTICULATION.

Bony formation. The anterior portion of the spinal hole of the atlas and odontoid process of axis.

Anterior and posterior ligaments, as in all the other vertebrae.

Transverse ligament, attached on each side to inner edge of oblique process of axis and by means of apparatus ligamentosus to cuneiform process above, and body of axis below.

Synovial membranes. One between posterior surface of odontoid process, and anterior surface of transverse ligament. Another covers the opposed cartilaginous surfaces of the atlas and odontoid process.

COMMON VERTEBRAL ARTICULATION.

Bony formation. Opposed surfaces of the bodies and oblique process of the vertebrae.

Anterior vertebral ligament, extends from axis to sacrum adhering to the bones and the inter-vertebral substances.

Posterior vertebral ligament, extends along the posterior part of bodies of vertebrae in front of spinal canal.

Inter-vertebral ligaments, or fibro-cartilages, are placed between the bodies of all the vertebrae, except the atlas and dentata, and united to their flat surface above and below. They are thicker in front than behind in the neck and loins, and the contrary in the back.

Synovial membranes and ligamentous fibres connect the oblique processes.

Ligamenta sub-flava, are situated between the laminae of the vertebrae from the second to the sacrum, completing the posterior part of the spinal canal.

Supra-spinous and inter-spinous ligaments, connect the spinous processes of the vertebrae.

Inter-transverse ligament, connect the transverse processes.

COSTO-SPINAL ARTICULATION.

Bony formation. Heads, and tubercles of ribs and bodies and transverse processes of vertebrae.

Anterior ligament,—origin, front of head of rib. *Insertion*, side of vertebrae above and below, and inter-vertebral substance.

Inter-articular ligament,—origin, projecting ridge in the articular surface of the rib. *Insertion*, cavity in the in-

ter-vertebral substance in which the head is received. The upper and lower divisions of this joint have distinct synovial membranes.

Inferior costo-transverse ligament, origin, neck of each rib. *Insertion*, transverse process of the vertebra above.

Posterior and external costo-transverse ligaments, connect the tubercle of each rib to the corresponding transverse process.

Synovial membranes are between the tubercles and transverse processes.

COSTO-STERNAL ARTICULATION.

The ribs are connected to the sternum through the intervention of their cartilages, which are secured anteriorly and posteriorly by ligamentous fibres.

LUMBO-SACRAL ARTICULATION.

Bony formation. Last lumbar vertebra and sacrum. These are joined together in the same manner as the other vertebrae.

Ilio-lumbar ligament,—origin, transverse processes of fourth and fifth lumbar vertebrae and back part of sacrum.

Insertion, posterior superior spinous process and crest of ilium.

ILIO-SACRAL ARTICULATION.

The ilium and sacrum are connected anteriorly and posteriorly by short ligamentous fibres.

Great sacro-sciatic ligament,—origin, lower and back part of posterior inferior spine of ilium and back part of sacrum and coccyx. *Insertion*, lower edge of tuber ischii.

Lesser sacro-sciatic ligament,—origin, side of sacrum and coccyx. *Insertion*, spine of ischium.

SACRO-COCCYGEAL ARTICULATION.

The sacrum and coccyx are united together by a similar substance to the inter-vertebral, and by ligamentous bands anteriorly and posteriorly.

PUBIC ARTICULATION.

Fibro-cartilage, attaches closely the bones of the pubis also ligamentous fibres.

Sub-public ligament passes from the ramus of one bone to the other and rounds off the angle formed by their union.

Obturator ligament, attached to the circumference of obturator foramen, except superiorly, where the thyroid nerve and vessels pass through.

STERNO-CLAVICULAR ARTICULATION.

Anterior ligament.—*origin*, anterior surface of sternal end of clavicle. *Insertion*, anterior surface of sternum.

Posterior ligament.—*Origin*, posterior surface of sternal end of clavicle. *Insertion*, back part of sternum.

Costo-clavicular ligament.—*origin*, lower surface of sternal end of clavicle. *Insertion*. Cartilage of first rib

Inter-clavicular ligament extends from the posterior surface of one clavicle to the other.

Inter-articular cartilage, thin below and attached to sternum; thick above and attached to clavicle; having a synovial membrane connected to each surface and its corresponding bone.

SCAPULO CLAVICULAR ARTICULATION.

Superior acromio-clavicular ligaments.—*origin*, upper surface of acromion. *Insertion*, upper part of clavicle.

Inferior acromio-clavicular ligament. Attached to under surface of each bone.

CORACO-CLAVICULAR ARTICULATION.

Conoid ligament, triangular; base connected to the tubercle on inferior surface of clavicle, apex at the broad part of coracoid process.

Trapezoid ligament, attached above to an oblique line on the clavicle; below to upper part of the coracoid process.

LIGAMENTS OF THE SCAPULA.

Coraco-acromial ligament.—*origin*, broad from corocoid process. *Insertion*, narrow into point of acromion.

Posterior or coracoid ligament.—*origin*, superior costa of scapula behind the notch. *Insertion*, base of coracoid process. This ligament converts the notch into a foramen.

HUMERO-SCAPULAR ARTICULATION.

Bony formation. Head of humerus and glenoid cavity of scapula.

Capsular ligament.—*origin*, circumference of neck of scapula. *Insertion*, around the neck of humerus.

Coraco-humeral ligament.—*origin*, coracoid process. *Insertion*, anterior part of great tuberosity.

Synovial membrane is reflected over the surface of the glenoid cavity around the glenoid ligament; lines the capsular ligament, head of humerus, and bicipital groove.

HUMERO-CUBITAL ARTICULATION.

Bony formation, articular processes of

humerus, great sigmoid cavity of ulna—head of radius.

External lateral ligament. *Origin*, External condyle of humerus. *Insertion*. Annular ligament of radius.

Internal lateral ligament—*origin*, internal condyle. *Insertion*, inner edge of olecranon and coronoid processes.

Anterior ligament consists of thin fibres. *Origin*, principally from above internal condyle and depression on fore-part of humerus, *insertion* annular ligament of radius and synovial membrane.

Posterior ligament is composed of fibres which extend from one condyle to the other, and are attached to the synovial membrane.

Synovial membrane is reflected from behind the anterior ligament to neck of radius and annular ligament. These line the sigmoid cavities of the ulna and is reflected to the lateral ligaments and tendon of the triceps muscle, which conducts it to the posterior depression of the humerus, and is then expanded over its articular processes.

SUPERIOR RADIO-ULNAR ARTICULATION.

Bony formation, lesser sigmoid cavity of ulna and inner side of head of radius.

Annular ligament—*origin*, anterior border of lesser sigmoid cavity of ulna *insertion* posterior border of the same cavity. It encircles the neck of radius.

Oblique ligament—*origin*, coronoid process of ulna, *insertion* radius below its tubercle.

Interosseous ligament connects the opposed edges of radius and ulna, its fibres descending obliquely inwards from the former bone to the latter.

INFERIOR RADIO-ULNAR ARTICULATION.

Bony formation round head of ulna, and sigmoid cavity of radius.

Sacciform ligament passes from radius to the ulna, forming a sac above the following

Fibro-cartilage—*origin*, styloid process of ulna, *insertion*, inner edge of radius below the ulna.

RADIO-CARPAL ARTICULATION.

Bony formation, lower end of radius; scaphoid, lunar, and cuneiform bones.

External lateral ligament—*origin*, styloid process of radius, *insertion*, scaphoid bone, and by some fibres into annular ligament and trapezium.

Internal lateral ligament—*origin*, styloid process of ulna. *Insertion*, cuneiform bone.

Posterior ligament—origin, posterior part of radius and fibro-cartilage. **Insertion,** back part of superior row of carpus.

Anterior ligament—origin, anterior part of radius and fibro-cartilage. **Insertion,** fore part of first row of carpus.

CARPAL ARTICULATIONS.

The bones of carpus are articulated by ligamentous bands, both anteriorly, and posteriorly.

An *internal* and *external lateral ligament* attach the two rows.

Synovial membrane extends between the two rows and sends processes between the bones.

Annular ligament—origin, trapezium, and scaphoid bones. *Insertion,* cuneiform, and unciform bones.

CARPO-METACARPAL ARTICULATION.

The carpus and metacarpus are secured by fibrous bands which pass in different directions, and cover the synovial membrane.

METACARPO-PHALANGEAL ARTICULATIONS.

The heads of the metacarpus and first phalanges are secured by *lateral ligaments*, and are lined by *synovial membranes*.

INTER-PHALANGEAL ARTICULATIONS.

The phalanges are connected to each other by means of lateral ligaments, and between each of their joints is a synovial membrane.

ILIO-FEMORAL ARTICULATIONS OR HIP JOINT.

Bony formation, acetabulum and head and part of neck of femur.

Cotyloid ligament, a fibro-cartilaginous circular band adhering to the edge of the acetabulum.

Transverse ligament, attached to the opposite points of the notch, and partly filling it up.

Capsular ligament—origin, circumference of acetabulum. *Insertion* below root of trochanter major, and the two inter-trochanteric lines.

Accessory ligament—origin, anterior inferior spinous process of ilium. *Insertion,* fore part of lesser trochanter.

Synovial membrane, reflected from inside of capsule upon periosteum of neck, and cartilaginous surface of head; is continued over inter-articular ligament, and thence is reflected upon the cartilaginous surface of the acetabulum.

Inter-articular ligament or liga-

mentum teres—origin, depression on head of femur. *Insertion* by two bands into the extremities of the notch, and by synovial membrane into the fatty substance at the bottom of the cavity.

FEMORO-TIBIAL ARTICULATION OR KNEE JOINT.

Bony formation condyles of femur and head of tibia.

Ligamentum patellæ—origin, lower angle of patella. *Insertion,* tubercle of tibia.

Posterior ligament—origin, tendon of semi-membranosus muscle at internal and posterior part of tibia. *Insertion,* external condyle of femur.

Internal lateral ligament—origin, internal condyle of femur. *Insertion,* internal condyle of tibia and semilunar cartilage.

External lateral ligament—origin, external condyle. *Insertion,* head of fibula. This ligament is often divided into two by the tendon of the biceps muscle.

Synovial membrane lines the back part of the patella, from which it is reflected two or three inches on the fore part of the femur, and on its condyles; from thence it is conducted by the crucial ligaments to the semi-lunar cartilages, and head of tibia.

Alar ligaments arise from each side of patella and unite below that bone. They are mere folds of synovial membrane.

Ligamentum mucosum—origin, fatty substance behind ligamentum patellæ. *Insertion,* hollow between the condyles. It also is a fold of synovial membrane.

Transverse ligament, attached to the anterior portion of each semi-lunar cartilage.

Anterior crucial ligament—origin, inner side of external condyle. *Insertion,* near the fore part of head of tibia.

Posterior crucial ligament—origin, outer side of internal condyle. *Insertion,* depression on back and external semilunar cartilage.

Semi-lunar cartilages, thick externally, thin internally; concave above, flat below. Their outer convex edges are attached to the lateral ligaments: their inner edges are free: the anterior and posterior extremities of each are attached to the head of the tibia. The outer cartilage is circular, the inner is oval.

TIBIO-FIBULAR ARTICULATIONS.

The head of the fibula is attached to the tibia by *anterior* and *posterior fibrous bands* and synovial membrane.

Interosseous membrane extends from one bone to the other, nearly the whole length.

The lower extremities of the tibia and fibula are connected together by anterior and posterior ligaments.

ARTICULATION OF THE ANGLE.

Bony formation, lower ends of tibia and fibula and astragalus.

Internal lateral ligament—origin, internal malleolus. *Insertion*, astragalus, navicular and calcis.

External lateral ligaments are three; all take their origin from the external malleolus. *Insertion* of anterior, upper and outer part of astragalus. *Insertion* of middle, os calcis. *Insertion* of posterior, ridge on the back of astragalus.

Anterior ligament—origin, anterior edge of tibia. *Insertion*, upper and outer part of astragalus.

ARTICULATIONS OF THE TARSUS.

The astragalus and os calcis have two articular surfaces, covered by synovial membranes.

Interosseous ligament passes nearly perpendicularly from the groove which separates the inferior articular surfaces of the astragalus, to the corresponding groove in the os calcis.

Posterior ligament is attached to the posterior edges of the astragalus and os calcis.

The bones of the tarsus are connected on their dorsal and plantar aspects by numerous ligamentous bands.

Calcaneo-navicular ligament—origin, inferior surface of os calcis. *Insertion*, inferior surface of os naviculare.

Calcaneo-cuboid ligament—origin, posterior inferior part of os calcis. *Insertion*, under part of cuboid bone, and third and fourth metatarsal bones.

Synovial membranes line the several articulations of the tarsus.

TARSO-METATARSAL ARTICULATIONS.

These joints are secured by dorsal and plantar ligaments, and are lined by synovial membranes. The metatarsal bones are secured to the phalanges, and the phalanges to each other by lateral ligaments and synovial membranes.

ON REMOVING DEFORMITY SUCCEEDING BURNS.

To the Editor of the India Journal of Medical and Physical Science.

SIR,—In the 16th No. of the 2d volume of your Journal, a case of operation

for “removing deformities succeeding burns of the arm and fore-arm,” is detailed by Mr Roberts of Bangor.

Having had lately under my care three cases of a similar description, I beg to state the plan of operation I adopted, somewhat different to that of Mr. R's. and a mode of subsequent treatment, which I am inclined to suppose better calculated to obviate this deformity.

The appearance which this deformity presents is, I believe, always the same,—a thin but deep bridle of integument connecting the arm and fore-arm, and forming at the elbow an angle more or less acute.—In performing the necessary operation, little more seems to be required than a simple incision dividing the integuments fairly to the bend of the arm, and keeping up proper and continued extension,—such is the opinion of Dupuytren and others. Performing this operation by a single incision, cannot I am persuaded, remedy this deformity to any great extent, as it will be almost impossible to prevent the cicatrix from again contracting as the wound heals. In one instance this took place in a patient under my care: I however, subsequently adopted the operation I shall now detail: one which will be found to answer better than either of those proposed by Dupuytren or Mr. Roberts. It consists in making two incisions, so close to the arm and fore-arm as to include a portion of the normal integuments of both. An incision of this description, giving to the excised part a triangular form: a good deal of blood necessarily flows, but it is easily restrained by pressure. The advantages of this mode appears to be, that the arm is brought immediately to nearly its natural form, and the wound, while the healing process advances, is much less disposed to contract. Lint smeared with a little simple ointment to cover the raw surfaces is now used, and two fracture splints, on the arm and fore-arm, are to be applied with moderate pressure. I now come to that portion of the treatment on which depends the success of the operation. This consists in keeping up a proper degree of extension by suspending from the wrist, a weight of at first lbiss, and increasing the weight as the cure proceeds; at the same time binding at the wrist and top of the shoulder an elastic piece of bamboo band, drawing with a bandage the centre of it towards the bend of the arm: this is of much consequence, as it forms an antagonist power to the flexors, which the

patient, to receive temporary relief from the suspended weight, constantly throws into action.

Two cases which I treated in this manner, have succeeded quite to my satisfaction; one of them a robust jail prisoner, who received the injury eight years since, the other a delicate boy of fourteen years, whose deformity was of four years standing.

I am, Sir, yours truly,

T. CHAPMAN, M. D.

Parneauh, January 11, 1836.

CASE OF TUBERCLES

IN

THE CEREBRUM, TERMINATING

IN

CHRONIC HYDROCEPHALUS,

By A. B. WEBSTER,

Assistant-Surgeon.

We beg to call the particular attention of our readers to the following case of tubercles in the brain drawn up with great care, discrimination and talent by Dr. Webster.

The case is important inasmuch as it proves that the formation of tubercles in this instance proceeded from a constitutional affection.

The distortion of the eyes and pendulous state of the eye-lids to which Dr. Webster alludes were in our opinion symptoms of the tubercular deposition in the brain.

M. J. W., aged $3\frac{1}{2}$ years, a girl of rather delicate constitution, but sharp and intelligent. Had an attack of hooping-cough last autumn which formed well and from which she had a good recovery, after labouring under it for several months. About the end of March last, her relations began to observe an unusual expression in the eyes, which were dull, heavy and shining, with great distortion of the balls, and a falling down of the eyelids, or in other words, an inability to keep them permanently raised. The eyeballs were turned obliquely upwards towards the inner canthus, more particularly the right one, which continued throughout to show a more unnatural appearance than the left; with all this there was apparently no disturbance of the general health, so much so,

that her relations, who were anxiously alive to the most trifling circumstance affecting it, did not think it necessary to consult their medical attendant, though sensible at the same time of the unnatural appearance of the eyes. Once or twice, during probably the space of a month, she complained of a pain in her head; but so slightly, and so transient it seemed, that little attention was paid to it farther than ascribing it to rather a costive state of the bowels, and prescribing for it a gentle laxative. She took her meals as usual, and was in her customary good spirits; but it began to be observed that she slept longer than formerly during her afternoon sleep; that more coaxing was necessary to keep up her attention whilst repeating her lessons, and that during her sleep her eyelids were only *half shut*; matters continued in this state for about a month, when no change taking place for the better, but on the contrary the eyes becoming more distorted with *dilatation of the pupils*, and rather an increase of the drowsiness, her friends got alarmed, and about the beginning of May, they consulted their medical attendant.

On examining the child, and taking into consideration the symptoms that then showed themselves, viz., the distortion of the eyes, their dull, heavy appearance—the dilatation of the pupils, which, however, contracted readily enough on the application of a strong light—the pendulous state of the eyelids—the repugnance of the child in her ordinary movements to look towards the light—and the drowsiness—all these being unattended with any decided pain in the head—acceleration of the pulse or febrile disturbance of the system—he (the medical attendant) had suspected mischief to be going on in the head, and treated the case accordingly; leeches were applied to the forehead and temples and were repeated in a few days after; a blister was put on the nape of the neck and kept open by means of the ung. cantharid.; the head was shaved; the bowels repeatedly opened, and the strictest attention to quiet and regimen enjoined. These remedies were continued for 8 or 10 days, and were followed up by a course of calomel, 2 grains 4 times a day. This treatment was pursued for 10 or 12 days longer, by which time upwards of 100 grains of calomel had been taken, when it was deemed proper to intermit the whole for a short time (about a week) to observe the effects produced and to allow the system to rally a little.

A slight change for the better seemed to have taken place. The eyes were less turned up, the eyelids less pendulous, and the child declared she had no pain in the head.* This apparent amendment, however, only continued for a few days. She now began to complain decidedly and loudly of pain in the head, which came on in evident paroxysms, and for the first time was attended with crying. She slept almost constantly, and with the *eyelids half shut*, but when roused she was as completely sensible as at any time during her life. The eyes became more distorted, and it was remarked that the head was a little enlarged and unequal, particularly on one side (the left) behind the ear. The pulse was sharp and wiry, ranging between 120 when asleep to 140 when awake. It may again be here repeated that until the medical treatment was commenced, the pulse was nearly natural; there was no heat of skin, and her appetite was good. In fact, as before observed, there seemed to be no disturbance of the system till the remedies were used, or if there was any, further than the tendency to drowsiness, it was so slight as not to be observed by her relations and attendants.

From the aggravation of the symptoms above described, and all attendant circumstances, there seemed little doubt now of her disease being chronic hydrocephalus; and its treatment was resumed with still more energy than before. The calomel was repeated in the former quantities; a brisk purgative of jalap and rhubarb was given every morning; the issue in the neck was renewed, and a copious discharge from it kept up, and the tartar emetic ointment rubbed on the head twice a day till a moderate eruption of pustules was produced. With all this treatment, however, little, or if any, only transient benefit seemed to be derived. Sometimes the attendants fancied a change for the better had begun to take place, but the morrow dispelled all their hopes. The drowsiness, distortion of the eyes, and paroxysms of head-ache continued and soon changed into complete stupor; the pulse rising to 150 and 160 and irregular. In this state the child remained upwards of a month, taking all the time a moderate quantity of food (such as sago, arrowroot, &c.) till the system gra-

dually and even imperceptibly giving way, she expired about the beginning of August.

During the whole progress of the disease, even from the commencement, it was remarked by the attendants and professional men, the large quantity of feculent matter brought away by the purgatives. It was incommensurate with the quantity of food taken into the system. Though the purgative was given every morning without intermission for upwards of a month, producing always two and sometimes three copious stools a day, yet at the end of that time, the quantity excreted daily continued undiminished, even up to within twelve or fourteen days of the child's death. Nor were the stools watery: the first was always thick and consistent, of a dark bilious colour, the others thinner and inclining to yellow. Convulsions of the arms and legs were frequent, though not severe during the last three weeks, and about this period there seemed to be a trifling degree of paralysis of the left side. Life in this child was peculiarly tenacious—so gradually and even imperceptibly did it ebb, that it continued to exist for a fortnight after mortification had attacked the integuments of the abdomen, neck and back.

An inspection of the head after death was permitted; but the object being only to satisfy the relatives as to the nature of the disease, by ascertaining the existence or otherwise of water in the ventricles, the dissection was necessarily hurried and superficial. On removing the skullcap, there were found strong adhesions between the dura mater and the posterior portion of the parietal bones, at which place the inner table was almost entirely absorbed, and presented the appearance of a piece of wood affected with dry rot; to this spot the child most generally pointed when asked as to the pain in the head. No separation of the sutures had taken place, but the skullcap was remarkably thin and diaphanous, and when it was removed, the dura mater under it seemed quite tinged as if distended with a large quantity of fluid in the ventricles, only between four and five oz. however were contained in them. The brain was firm, but the pia mater and tunica arachnoides had no marked inflammatory appearance; on cutting off a portion of both hemispheres on a level with the foramen, several round tubercles, of the size of a pistol bullet, and of the colour and consistence of Dutch cheese, were imbedded in the substance of the brain.—

* This Child was so intelligent that we could rely on the correct description of its feelings.

There were about five or six of these tumours altogether; but there was one larger than the rest, about the size of a walnut, situated towards the base. On taking another slice off the hemispheres, there were observed two cavities or sinuses, situated in the middle lobes of the cerebrum, one on each side of an extent capable of containing a moderate sized kidney bean. No trace of water or pus could be detected in them. Their walls were pulpy and softer than the rest of the brain; and so near the surface were they, that the outer wall of the one on the left side was not above the thickness of a shilling; in fact it might almost be said that the surrounding membranes formed the walls at this side. No communication with the lateral ventricles could be seen. The cavities of the chest and abdomen were not opened, as no peculiar morbid affection was effected to be found in them.

On reviewing the particulars of this case, there are several circumstances worthy of notice, and first as to the commencement of the disease. There is great reason to believe that the deposition of tubercular matter was the first stage; and that this was not attended with much vascular action in the head, is probable from the almost total absence of headache and of general disturbance of the system, even when the appearance of the eyes and drowsiness indicated that something unusual was the matter with the child. It is also not unlikely that these symptoms (distortion of the eyes and the drowsiness) were caused by the pressure of the tubercular masses on the brain rather than by the existence of water in the ventricles, which, it is more than probable, did not take place till a period very little anterior to the supervention of the stupor, or about the time when the pain in the head came on in paroxysms attended with crying. Could the formation of the tubercles have had any connexion with hereditary indisposition? Were they a constitutional or merely a local affection? The following circumstances give a probability to their being constitutional. The only brother (a year younger) of this child died six months before of a tubercular affection of the liver, accompanied with, or rather terminating in, effusion into the head. The liver was immensely enlarged, and studded with tubercles bearing a great resemblance to those in the brain of the girl. The mesenteric glands were also slightly enlarged. The mother of these children,

too, died within a few days of the boy, of tubercular consumption. The distortion of the eyes and the pendulous state of the eyelids were the symptoms that first presented themselves and attracted the notice of the attendants; the child in other respects seemingly being in her usual health, walking about and taking her food as if nothing was the matter with her. Is this the usual way in which hydrocephalus attacks, or may these symptoms more particularly indicate the commencement of the tubercular deposition in the brain? The two sinuses—How were they formed? Were they the seat of tubercles which had been softened down and absorbed, or were they regular abscesses, containing at one time pus which had been absorbed? Lastly, the quantity of feculent matter discharged from the bowels—Was this a feature of this peculiar disease, or was it the consequence of the use of the calomel?

CANINE PATHOLOGY.

To the Editor of the India Journal of Medical and Physical Science.

Dear Sir,—If canine pathology is not beyond the pale of the Medical and Physical Journal, so ably edited by yourself and copiously supplied with interesting matter, may I ask the favour of you, to give the following concise case a portion of your columns. It will be interesting to the sportsman, and I hope not less so to the physiologist. On the 1st September, 1835, I was asked by a lady to administer some relief to her favourite dog Rover, a large pointer, five years old, which she thought to be in a very hopeless condition. Being anxious to save the life of a sagacious and amiable creature, I inspected poor Rover, and found him suffering under the lank distemper, with an ulcer extending over the whole upper jaw, exposing the cartilages of the ear and threatening the eye; it was about a quarter of an inch deep, in a horrid sloughing state, with maggots. I even had some suspicion that the brain was not untouched. Before I tried any remedy I referred to Mr. Blaine's famous work on canine pathology, and found the treatment for lank distempers, but nothing which would serve the desperate condition of the ulcer. In the lank, canine distemper, the object of the veterinary surgeon is first to remove the visceral

obstruction: for which Mr. Blaine mentions remedies; these I did not think would answer Rover's case, and made trial of the sol. chlo. soda in ad. cinnamon, 30 drops of the former to an $\bar{3}$; of the latter, ter. in die, ol. ricini $\bar{3}$ ss., ordering the ulcer to be washed with brandy and water, and covered with cloth dipt in tinct. myrrh.

Sept. 2.—The oil has operated freely; he has taken the soda draught once in the evening; the dog is not so dull. Ulcer is cleaner, but there is still considerable sloughing. Directed the application of chalk and charcoal in fine powder, to continue tinct. myrrh; diet, a little meat boiled in rice.

3rd.—The ulcer is clean; the extent of the disease is now exposed. Tongue of a lead colour, indicating an accession of disease; nose dry—a bad symptom in dogs, according to Mr. Blaine; another dose ol. ricini was given and the soda draught continued; the edges of the ulcer touched with nitras argenti. It was impossible to keep on any plasters on account of struggling.

4th.—Rover is more cheerful: treatment continued; omit the tinct. myrrh, and dash salt water cold upon the ulcer, which is indolent.

6th.—The dog is thinner, and somewhat weaker; omit aq. cinnamon and sol. chlo. soda; tongue dirty; nose more moist; ulcer indolent.

R. Pulv. jalap, gr. xv.

Potas supertar, gr. xxx.

Aq. menth pip. qs. M. ft. haust. stat. sumend.

7th. — Improvement: there seems healthy action in the ulcer; dash with salt water. Diet the same; more in quantity.

8th.—Much the same.

R. Pulvis cinchon lancy, $\bar{3}$ jss.

Aq. fon. qs. x. M. ft. haust.

Stat. sumend.

With this treatment, and now and then a purgative, he has quite recovered.

Yours,
J. G.

Sulkea, Feb. 1836.

GENERAL HOSPITAL.

To the Editor of the India Journal of Medical and Physical Science.

Dear Sir,—The accompanying cases of protracted labour, &c. in which the administration of the ergot of rye appeared

to be followed by decided advantage, will probably be considered by you worthy of a place in your valuable periodical!

Yours truly,

WALTER RALEIGH.

March 9, 1836.

Case 1.—I was summoned in great haste by an European midwife to see the lady of a captain of a ship who had been brought to bed of a male child eight hours previously, and notwithstanding that the nurse had made every effort to remove the placenta, she had been unsuccessful in her attempts. A rather copious hæmorrhage had existed for a considerable time, the patient was perfectly pale from loss of blood, the skin cool, lips vivid, pulse scarcely perceptible at the wrist, and she frequently fainted.

On examination, I found the abdomen soft and distended, and that no contraction of the uterus had taken place. The usual cold applications, &c. were had recourse to: and ergot of rye $\bar{3}$ j. having been infused in $\bar{3}$ ivss. of boiling water, one-third part of the infusion was administered as soon as prepared.

No change having taken place after twenty minutes, I repeated another third part of the mixture. In ten minutes after taking this second dose, uterine pains began to be felt. The muscular contraction soon became active, and with the assistance of gentle extension by the umbilical cord, the placenta was brought away, and the womb contracted firmly. Coagula continued to be cast off for two or three days, and the patient rapidly recovered.

Case 2.—I was called to see a young woman of about seventeen years of age, who had been thirty-six hours in labour: it was her first confinement, and the European nurse, although a skilful midwife, was in great alarm. The pains which had at first been severe and frequent, had for several hours entirely ceased; the patient was deadly pale and much exhausted, with a feeble pulse, and skin suffused with perspiration. On examination per vaginam, I found the os uteri dilated, the membranes protruding in a pointed form, and that the feet presented with the toes turned towards the pubis of the mother.

I instantly administered a scruple dose of the ergot of rye, which having no effect, after half an hour I repeated; this second dose seemed to occasion a slight return of uterine contraction, but as it was but in trifling degree, I gave a third scruple dose after a second half hour had

elapsed; in about fifteen minutes after which, vomiting ensued, followed by active uterine contraction, the membranes burst, and labour advanced unaided until the thighs of the child came fairly into the vagina, and admitted of a firm grasp, when I turned the child so as to bring its face towards the sacrum of the mother, after which the labour proceeded naturally, and the mother and child did well.

Case 3.—Occurred in a delicate young woman, the wife of an Assistant Apothecary at the General Hospital; she had been more than twenty-four hours in labour, and the pains, when I was called to her assistance by her mother, who is a midwife, had ceased; she was much exhausted and very faint. Examination indicated that the os uteri was fully dilated, but that the membranes had not ruptured; she took fifteen grains of ergot of rye with no effect. A second similar quantity was administered after twenty minutes, which in the course of a quarter of an hour was followed by vomiting, and strong uterine pains. The membranes gave way, and she was delivered within two hours after taking the first dose of rye.

Case 4.—The lady who was the subject of this case, was a friend of Mr. Foy, our very able Apothecary of the General Hospital. As he attended the patient throughout her indisposition, I requested him to draw up her case himself, a verbatim copy of which I now give. "An East Indian lady, of delicate habit, had been suffering thirty-six hours in her first labour; the membranes had broken, but the pains had been inefficient and sluggish, and during the past five hours entirely suspended; the patient was exhausted, irritable, and had distressing hiccup. Dr. Raleigh prescribed at this time fifteen grains of the ergot of rye, infused in water, every half hour. Two hours from the first administration of the medicine, and after she had taken three doses, the uterine pains became brisk and frequent, and delivery took place within three hours from the first dose of the remedy."

Case 5.—A patient of the General Hospital in her sixth confinement had been suffering for forty-eight hours from inefficient labour pains; the membranes had given way in the early stage, and the presentation was perfectly natural, but for the last four or five hours the pains had ceased, and the woman had become much exhausted; fifteen grains of the ergot of rye were prescribed in powder

every half hour; after taking the third dose, vomiting was induced, the uterine pains became energetic and rapid, and delivery was speedily effected.

WALTER RALEIGH.

March 9, 1836.

GASTRO ENTERITES.

W. B., æt. 46, an old soldier, of haggard appearance, pale and contracted features, but of immense muscular and bony formation, is suffering from an old diarrhœa with a dull, heavy pain at scrobiculus cordis, a troublesome cough, unaccompanied by expectoration, a dry rigid skin, sleeplessness, loss of appetite and general weakness. Pulse is full, soft, and regular, tongue glossy, brick red, and moist, stools thin, light yellow mucus, and glairy, with small black or dark green morcela, as of boiled peas, and white particles like rice or curdled milk. No fullness to be felt in either hypochondre, but there is pain on pressure in the umbilical region, and on stretching the arms above the head, or making any exertion of the abdominal muscles. His most comfortable posture is on his right side or back with the knees drawn up. Percussion and auscultation discover to the observer's unpractised ear no appreciable lesion of lungs. The case in its general nature is one of every day occurrence, viz. a constitution naturally robust broken down by dissipation, abuse of spirits, and effects of climate. The state of the tongue, the character of the expectoration, the sound of the voice, the colour and appearance and smell of the stools are the only indications in the treatment.

During twenty-four days that he lived in Hospital, a variety of treatment was followed. From four to three and two leeches were applied daily for a time over the epigastre; blisters round the umbilicus; minute doses of calomel with digitalis and opium were given three or four times a day, and the bowels cleared by castor oil, &c. every day or two.

Emaciation however, proceeded; nothing like healthy secretion was procured; the tongue became varnished, nay polished, dry and bright like a carriage panel, its colour a dingy brown. Bark was now tried in ʒss. doses with ʒ gr. of carbon. ammoniæ, and ʒ of hyd. c. creta three times a day; and for a few days with good effect. Finally, recourse was had to the nitric acid and black drop, but in vain. In truth the case was all along a hopeless one.

On post mortem examination the whole mucous membrane of stomach and duodenum was found to be softened, the muscular coat white, firm, and much thickened like boiled tripe. Within the stomach, the mucus membrane at the cardiac extremity was thickly studded with minute red spots of petechiæ, in patches the size of a rupee; towards the pylorus, and along the duodenum it exhibited a uniform pink blush in streaks alternating with pale. The mesenteric glands were hard, cartilaginous white, with a drop of pus or tubercular matter in the centres. The omentum was a firm membrane opaque and thickened; it adhered firmly to the parieties of lower abdomen to the caput coli and the ilium. The whole of the lower bowels were glued together by coagulable lymph. Some discolouration and minute ulceration of the caput coli.

The liver was tolerably healthy, its upper surface adhered to the diaphragm from old inflammation. The gall bladder was very large and the ducts contracted.

Remarks.—No indications of intestinal disease are so little understood, as those of the tongue, yet none appear to merit so much study from their eminent importance. Even the French pathologists, who take the lead in researches of this sort, Andral, Martinet, and Rostan deal but in generalities in describing the morbid state of this organ. “La langue seche, indique la probabilité d’une phlegmasie de l’estomac on de l’intestine grele.”—Martinet. And “cet état de la langue annonce une irritation d’autant plus violente des organes gastriques, *pulmonaires* ou autres, que cette secheresse est plus prononcée.”—Rostan. Andral says in conclusion of his observations. “Les mêmes phénomènes revelent le plus ordinairement pendant la vie les alterations organiques de forme et de structure les plus différentes.”

Do not remember any mention of this tongue by Dr. Abercrombie in conversation or in writing. Nowhere indeed do I find any mention of this *highly varnished dry brown* tongue, which I have seen repeatedly, and have heard Mr. Twining speak of, as indicating muco jejunal inflammation.

In the only two cases which I have had an opportunity of examining after death, there existed the petchial state of the mucus membrane of the stomach above described; the result apparently of low chronic inflammation in debilitated subjects and weakened vessels.

KREOSOTE.

There have been several cases of cutaneous disease in Hospital lately, furnishing an opportunity of trying the new German remedy the *Kreosote*, of which the following is a concise account:

This interesting substance, recently discovered by M. Reichenbach, in impure pyroligneous acid, has been applied with great success, both internally and externally, as a remedy for numerous diseases, particularly in obstinate cutaneous affections, recent wounds, ringworm, &c. and by inhaling in disease of the bronchia and lungs. The following directions for its employment will serve as a guide to the medical practitioner.

INTERNAL ADMINISTRATION.

In spitting of blood, catarrhal affections, and obstinate vomiting, in doses from two to six drops, three or four times a day, either of solution, (two drops being soluble in one ounce water,) or in the form of pills, mixed with liquorice-root powder and mucilage.

In affections of the bronchia and lungs it may be most advantageously applied by inhalation, for which purpose pour into an inhaler, capable of containing a quart, a pint and a half of water, at a temperature of 150 degrees, adding to it thirty or forty drops of the pure Kreosote, mix by agitation, and inhale the vapour through the tube.

EXTERNAL APPLICATION.

Kreosote may be employed externally, in three different forms, either pure, mixed with water, or united with simple cerate or lard, as an ointment. One dram of Kreosote, mixed with one pint of water, forms a lotion, which may be freely applied to recent burns or scalds, to chafed surfaces, and as for unhealthy ulcers, it may be applied undiluted to such parts as may require it, in the manner of a caustic; as an ointment, the usual proportion is thirty to forty drops to the ounce; in many cases it may be employed much stronger.

In Tooth-Ache, a drop introduced into the cavity, previously dried with a bit of cotton, will in most cases give immediate relief.

The employment of this substance in ringworm, and similar diseases of the skin, has been attended with the greatest possible advantage, some practitioners considering it a specific. The strength

to be employed in these cases must be regulated by the state of the eruption.

It may also be usefully employed undiluted, as an application to corns, warts, &c.; and also in solution, or diluted as an injection in leucorrhœa, gonorrhœa, &c.

It is highly important that this substance be employed in a state of purity, or entirely free from certain deleterious principles, naturally mixed with it in the compounds from which it is obtained.

M. Buchner, of Munich, recommends an alcoholic solution of kreosote, in the proportion of one dram to one ounce of alcohol, as an application to carious bones and teeth; and also proposes as the best mode of preparing kreosote water, to drop this alcoholic solution into distilled water, until it ceases to dissolve it, or becomes milky.

In three cases of adult ring-worm it seemed to do decided good; in two children it effected a speedy cure; in a case of caries tooth the relief from one drop was immediate and permanent; in a case of chronic rupia, and one of herpetic scaly disease dependent on old constitutional derangement, it rather did harm. In an irritable and scrofulous ulcer it allayed irritation, and seemed to act sedatively like its powerful prototype, the hydrocyanic acid and lead lotion; upon the whole from the result of ten cases, I am disposed to think that this will prove a valuable addition to our Indian *médicinals*, where skin diseases are so numerous and troublesome; and it may sometimes succeed where all other known agents have failed. I should mention that the drug was kindly supplied to me for trial by Messrs. Bathgate and Co., and that Dr. Jackson is now engaged in attempting its very laborious and difficult preparation at the Company's Dispensary.

D. S.

CASE OF CONGENITAL CATARACT IN A YOUTH OF 18, RESTORED TO SIGHT BY OPERATION.

BY T. H. BRETT, ESQ.

Khundoo Pundit, native of Saugor, was born blind; his mother states that she had kept him in a dark room until the tenth day after her confinement, when on taking him to the door, and exposing his eyes to the light, she discovered the pearly appearance of the pupils peculiar

to cataract, and that he has always been blind.

He is intelligent and cheerful, and has been in the habit of finding his way about Saugor, and the adjoining country, for many years, frequently singing, of which he is very fond. He had little or no inclination to undergo the operation, at least not sufficient to overcome the fear which he entertained. He could perceive the light, and had acquired the habit of rotating the head constantly in progression in a regular and curious manner, to the right and left, with a view, I imagine, of admitting the light to the retina, obliquely between the circumference of the cataract and the under edge of the iris. It was a long time before his relations could persuade him to submit to an operation.

He had requested to be taken to me some months previous, gratified at being told that he might be made to see like other people; but the slight inconvenience attending the introduction of a few drops of the solution of belladonna into the lids, and my holding the lids to try how they should be supported, annoyed him, and he said he would much sooner go home and eat his dinner. "What do I want with being restored to sight?" His mother likewise expressed her disbelief as to a person born blind being made to see. The principal Pundit of the Mohulea at length overruled the objections.

Appearance of the cataract. It was evidently entirely membranous, studded with a great number of pearly spots. The operation was performed on the 28th of August, with a delicate straight sharp double-edged needle, introduced in the usual position for cataract, and carried horizontally forward. Its substance, which was of very tough consistence, cut into two or three shreds, and left principally in the anterior chamber, without submitting the delicate organ to much irritation by too often repeated motions of the instrument. He complained of but little pain, and indeed there was scarcely any inflammation whatever produced by the operation. He immediately became conscious of a considerable increase of light.

The eye-balls, as in all cases of congenital cataract, moved about without any controul, which together with a very prominent superior orbital process, and much spasmodic action of the orbicularis, offered great apparent obstacles to the introduction of the needle, and it was quite im-

possible to use any speculum, or to support the lids at all, which would only have increased the irritation; I therefore find in all such cases it is better to introduce the needle without supporting the lids at all, which has an instantaneous effect in keeping the eye-ball steady. The operator can see sufficiently distinctly to direct the necessary movements of the needle. The native operators seldom hold the lids in any case.

So little irritation had occurred, that I operated this day, the 30th August, on the left eye, which resembled the former operation in every particular. No inflammation followed, but the right eye had become inflamed, in consequence of which his eyes remained bandaged for several days, and it became necessary to bleed him, and counter irritation was employed. He was purged with calomel and antimony, and leeches were once applied to the eye-brows.

He expressed himself as sensible of a remarkable change having taken place. The light was most distressing to him, and continued so for some time.

On the 8th day the absorption had proceeded very satisfactorily, several substances of various colours were presented to him. He could not recognize any of them until he had made himself acquainted with them by the sense of touch. He brought them very close to his eyes, moving his head in his accustomed peculiar manner. Whatever he attempted to reach, he always missed his aim at it. He expressed himself as highly gratified, and confident that he would see and know every thing, but did not like too much interrogation.

On the 12th day he came to me again. The eyeballs were no longer rolled about in their former vacant manner. He had acquired the power of directing the left eye, which had been most instructed, on objects. The right eye from inflammation, having remained bandaged. A lady showed him her shawl; he said it was red, which was correct, but did not know what it was, until examined by the hand. The platform in front of the house was recognized as green, and his mother said he had been examining many things at home. The absorption of the cataract had proceeded, leaving two-thirds of the pupils of the left eye quite clear; some inflammation still in the right. He said he was no longer afraid of me, and that he would submit to any thing I recommended.

On the 16th of September, he walked

from the town to see me, accompanied by his mother. He had gained much information during his absence. The pupil of the left eye had become almost entirely clear. He said he had seen a great number of trees on the road, the lake, and a buggy passing by. He had now made himself acquainted with several things. What is this? A lota. This? A pawn leaf. Which answers were correct. A small hooka was shown him, he touched it, and was told what it was; several things were then presented to him, and the hooka was again brought. He observed, "I cannot tell; you have submitted so many things to me, that I am confused, and forget their names." He felt it, and then exclaimed it is the same hooka. Presently it was shown him a third time, he recognized it after having carefully viewed it from top to bottom without touching. He observed a book, remarking that it was red, a table, black and gold, but he knew not that it was a book until told so. It was presented to him a few minutes afterwards, and he recognized both the colour and the book. He said he was extremely happy, and gratified with all he saw. He followed me with his eyes as I moved about the room, and pointed out the different positions I took. He recognized distinctly the features of his mother's face. She hid it under her chudder, he laughed, and observed that she had done so, and turned his face away. He said I can see every thing; all I want more, is time to learn what they all are, and when I can walk about the town, I shall be quite satisfied. He could not ascertain whether any thing was round or square, smooth or rough. He distinguished the following: some partridges, the cage, and the cup containing the water. The colour of their plumage he correctly stated, also the windows, the fields, the sky, a child in arms, &c.

On the 17th he again came to see me. He pointed out every feature in his mother's face; her hair, the colour of her dress, the different distances and positions which she purposely took, and when changing places with another woman, selected her out. He stated, that if I would bring the red book I showed him yesterday, he would recognize it. I accordingly brought him a red morocco box, much resembling the book, but smaller: he said it was the book!

From this period I quitted Saugor, and have heard nothing further of him.

NOTES OF LECTURES ON PHYSIOLOGY.

By DR. FLETCHER.

*Delivered in the Argyle Square School of
Medicine, Edinburgh.*

No. XXIV.

GENERAL OBSERVATIONS.

Scope and Utility of the Theory of Medicine—Manners and Feelings proper for studying it—History and progressive Advancement—Plan adopted in these Lectures—Order in which the different Topics should be treated—Physiological Circle of Hippocrates—Remarks by Dr. Hunter—Necessity of Simplicity and Precision—Irritability and its Stimuli—Organic and Animal Functions—Respiration and Sensation—Pathology—Etiology, and its Subdivisions—Semeiology—Diseased Alterations in Organs—Diseased Alterations in Functions—Therapeutics—Diet, Regimen, Medicines, and Surgery—Elementary Physiology—Apparatus subservient to the different Functions—Comparative Anatomy—Utility of Illustrations, Specimens, Preparations, and Diagrams—Etiology—Difference between predisposing, exciting, and proximate Causes of Disease—Difference between a proximate Cause and the Disease itself—Pneumonia, Apoplexy, and Angina Pectoris—Galen's stupid Definition, stupidly copied by Gregory—Error of Dr. Paris—Example of an internal exciting Cause—Predisposing Causes—Period of Life—Infancy, Boyhood, Adolescence, Maturity, and Senescence; and the Diseases to which they are liable—Cause of congenital Cataract—Specific Contagions—Superior Longevity of old Women—Greater Uselessness of old Men—Cullen's Theory of increased Determination of Blood at different Ages—His erroneous Views on Hæmorrhage—Temperament—Ancient and Modern Divisions—Sanguine, cho-

No. 8.

leric, melancholic, and phlegmatic Temperaments—Athletic, nervous, moist, and dry Temperaments—Cephalic, thoracic, and abdominal Temperaments—Examples—Charles Fox, Sir John Leslie, Lord Jeffrey, Lord Brougham, Dr. Birkbeck, a London Alderman, a Prize Fighter, a Naval Captain, Don Quixote, and a Wesleyan Minister—Characteristics of the different Temperaments; and the Diseases to which they predispose—Description of the lowest Grade of Humanity—Difference between Temperament and Idiosyncrasy.

Having made these observations upon the scope and utility of the theory of medicine, upon the manner of conducting that study, and upon the feelings by which those engaged in it should be actuated, I proceed now to describe, as shortly as possible, the general plan which I adopt in these lectures. I have already said how important it is, that persons engaged in the pursuit of any science, should have some knowledge of its history and progressive advancement; but it does not follow that the account of this advancement should precede, (as by many lecturers on all branches of philosophy it is made to do) the account of the things themselves. If the facts of a science cannot be well understood, without frequent reference to those who have established them, and of whom our hearers probably know nothing; neither can the merits of the improvers of the science be duly appreciated, without frequent reference to facts, of which probably they are equally ignorant. But in which case are we required to suppose the least:—in treating of the facts of a science before its history, or in treating of the history of a science before its facts? Unquestionably in the former; and therefore I must consider the common practice of prefacing a course of lectures with a history of the science to be treated of, as one "more honoured in the breach than the ob-

servance." If a general history of the science be delivered any where, I conceive it is more useful at the close, than at the beginning of such a course; more especially as the facts of a science, being of greater importance than its history, should have appropriated to them that period at which the energies of our hearers are most fresh and vigorous. I am in the habit, therefore, of plunging at once *in medias res*; but to determine in what order these should be treated of, is a matter of very considerable doubt and difficulty. With regard to elementary physiology, it was a remark of Hippocrates, which has been very frequently repeated, that every process going on in the living body, constitutes a portion of a circle which has neither beginning nor end; and in describing which we may set off almost where we please. In this respect it is quite impossible to do wrong; but, for the same reason, it is quite impossible to do right. "Wherever we begin," says Dr. Hunter, "we find that there is something preceding which we ought to have known. If we begin with the brain and nerves, for example, we shall find that these cannot exist, even in idea, without the heart; and if we set out with the heart and vascular system, we shall presently be sensible that the brain and nerves must be supposed. Or should we take up the mouth, and follow the course of the aliment, we should see that the very first organ that presented itself supposed the existence both of the heart and brain."

In treating of a science, then, where so perfect a *carte blanche* is offered to us with respect to arrangement, it appears to me the best plan, as being most conducive to simplicity and precision (which are the only legitimate objects of arrangement of any kind), to begin with the consideration of irritability; or that property which especially distinguishes living matter from dead; and of those stimuli, from the action of which on the irritability of the several organs of the body, all the functions of living animals directly or indirectly result. In prosecuting these several functions, I think it best to treat first of those which appear to imply the possession of irritability alone, and to be more or less common to all living beings, such as respiration, and the other functions commonly called organic; and afterwards to treat of those which seem to imply the possession of other properties superadded to irritability, and to be more or less proper to the higher classes of

living beings, such as sensation, and the rest of these commonly distinguished by the name of animal.

Such, then, is the general arrangement which I follow in treating of elementary physiology, and which I prefer to innumerable other plans, which, if not more perfect, are certainly by far more complicated. With regard to etiology, I see no good reason for deserting the established division of the causes of diseases into pre-disposing, exciting, and proximate. Under these respective heads, therefore, I shall treat of the influence, first, of all those permanent conditions of the body, and of all those accidental variations of circumstances affecting it, from which morbid changes result; and afterwards of all those morbid changes themselves which more immediately give rise to diseases. In treating of semiology, I shall endeavour to explain, in the first place, the changes effected by disease in the aspect of the various organs of the body, and their secretions; and, secondly, the changes effected in the various functions; following up these in the same order, as they were described in the state of health. Lastly, in treating of therapeutics, I shall follow the old division of remedies, into those referable to diet and regimen, to medicine, and to surgery; and shall investigate the influence, under each of these heads successively, of all those curative agents of which we avail ourselves in the treatment of diseases.

With respect to elementary physiology, although I take it for granted that my hearers in general are acquainted with all the broader facts of anatomy, I shall not allow myself to be so far misled by this idea, as to omit prefacing the account of every function with a slight description of the apparatus immediately subservient to it; and this, not in the human body alone, but in that of the lower animals also; since it is obviously impossible that we can reason fully or justly on the functions of any organ in the human body without some knowledge of the structure of the corresponding organs in the inferior animals, and of the means by which the same function is performed in them. It is only by proceeding in this way, from things simple to things complicated, that we can be made to understand what parts are essential to each function in man, and what are merely supernumerary; and can escape many false conclusions into which a more circumscribed view of the matter would necessarily lead us. At the same

time, I am perfectly aware how useless it is to be continually harping upon the mere names of such animals, and describing their organs and functions, while perhaps the majority of our hearers are hardly conscious of their existence, and know absolutely nothing of their nature. In order as far as possible to remedy this evil, I generally present a rough diagram, as well as give a short description, of those parts in the lower animal to which I have occasion more particularly to allude; and under the same conviction of the greater impression always made when the images of the things talked about are presented to the senses, I endeavour to illustrate, in the same way, every subject of human physiology, as it successively comes before us. Of the diagrams, for instance, which relate to the function of respiration, the first parcel is intended to illustrate the respiratory process in the invertebral animals, according as they breathe by gills, bladders, or tubes. The second set contains those which illustrate the same process in fishes, reptiles, and birds; and the third and fourth, those illustrative of the same process in the mammalia, and especially in man. The several subjects connected with pathology and therapeutics are less susceptible of this kind of illustration than those of elementary physiology; but it will, in the same degree, become less necessary; for if we thoroughly understand the functions of the healthy body, there will be little difficulty in following up all the changes induced in it by disease; and in understanding how it is liable to be affected by the various agents by which either diseases are occasioned, on the one hand, or health is restored, on the other.

ETIOLOGY.

The causes of disease are divided into three classes:—1. Predisposing. 2. Exciting. 3. Proximate. A predisposing cause consists of a permanent condition of the body, not sufficient of itself to cause disease; but which becomes sufficient when conjoined with an exciting cause. An exciting cause is some accidental variation of circumstances. The proximate cause is some morbid change in the functions of the body. Dr. Brown said that health and disease were the same condition; varying only in the degree of excitement. Two conditions are necessary for both; a stimulus to act, and a susceptibility of being acted upon. The irritability of an organ, and a stimulus

acting upon it, gives rise to a series of motions; and the result is a function. A morbid irritability and stimulus are the predisposing and exciting causes; giving rise to a morbid series of actions, (the proximate cause), of which the result is diseased function, or a disease.

Many deny the existence of any proximate cause; for they consider it identical with the disease itself. But the disease is always obvious, while the proximate cause is often obscure; and therefore they cannot be identical. Pneumonia is a series of symptoms, of which the proximate cause is inflammation of the lungs. A person may recognize pneumonia again, though he may know nothing of the lungs. It is the same with apoplexy and other diseases. We can tell angina pectoris, for instance, though we do not know its cause. Galen gave a stupid definition of an exciting cause, which has been copied by succeeding authors, down to the time of Gregory. It implied that between the exciting cause and the disease there was an essential connection, but not causation. It has also been incorrectly said by Dr. Paris, that being coexistent with the disease, it cannot be its cause; and by others that being part of the disease, it cannot be its cause. Predisposing causes are always internal; exciting causes may be either internal or external. Sleep which, in excess, produces disease is an example of an internal exciting cause.

Predisposing causes.—These consist principally of peculiarities in the irritability of different organs of the body, in certain conditions.

1. Period of life.—The age of man has been divided into five periods:—1. Infancy; extending from birth to seven years. 2. Boyhood; extending from seven years to sixteen. 3. Adolescence; from sixteen to twenty-five. 4. Adult Age; from twenty-five to fifty. 5. Old Age; from fifty to death. The two last are each subdivided into three periods. 1. Commencement. 2. Maturity. 3. Decline.

In childhood, the head is thought to be most liable to disease; in adult age, the lungs; in old age, the abdomen. In the two former, the predisposition may be owing to increased irritability, from the great supply of arterial blood; but in old age it is from nervous plethora, and depends, not on increased irritability of the capillaries, but on an increased stimulus.

(1.) Infants are liable to purulent ophthalmia, rubeola, scarletina, variola, vari-

cella, frambesia, and pertussis. These arise from specific contagions; and therefore age is not properly a predisposing cause to them. They are also liable to *tubæ mesenterica*, diarrhoea, parulis, aphthæ, strophilus, pityriasis, erysipelas, *arachnitis*, hydrocephalus, rachitis, hydro-rachitis, epilepsy, and trisurus. Of these, gastro-enteritis is the exciting cause. A third class of diseases to which infants are liable, includes cynanche trachealis, bronchitis, intus-susception, prolapsus ani, inguinal and umbilical hernia, scleroma, and polysaræia. Congenital cataract is rather defective organization than a disease; for the lens is always opaque before it is transparent; and it becomes transparent as its density increases.

(2.) Children are liable to many of those diseases to which infants are subject; and, in addition to tubercles, encephaloid tumours, morus, otitis, cynanche tonsillaris, chorea, epistaxis, and urinary calculi. Morbus coxarius, white swelling, and psoas abscess are included in tubercles.

(3.) Adolescence is liable to consumption, distortion of the spine, disease of the hip, &c.

(4.) Adults are more exposed to fevers, rheumatism, mania, dyspepsia, inflammation of the lungs and liver, tetanus, &c.

(5.) Old age is subject to apoplexy, gout, diseases of the genito-urinary organs, scirrhus of all the organs, hypochondriacism, diseases of the heart and blood-vessels, hæmorrhoids, &c. Old women retain their strength longer than old men, the former being intended by nature to wait upon the latter; and we should therefore rather speak of an "old man" as useless, than of an "old woman." Women likewise live longer than men.

Many diseases are put down to age as a predisposing cause of which it cannot properly be considered a cause at all. We are liable to them only from being in certain situations; and if in those situations we should contract them at any age. Instead, therefore, of a particular age being a predisposing cause of them, we are more exposed to the exciting cause of them at that particular age.

Predisposing causes are generally explained on the principle of increased determination of blood. Hence, according to Cullen, hæmorrhage takes place from different parts of the body, in different periods of life; from the nose in childhood, the chest in maturity, and the anus in senescence. His theory is improbable,

hypothetical, gross, and mechanical. He struck a balance between the pulmonary and aortal systems; and attributed all pulmonary diseases to the pulmonary system of blood-vessels. Hæmoptysis, however, takes place not from the pulmonary but from the bronchial vessels; and therefore from the aortal system, which Cullen denied.

II. Temperament. Temperaments were anciently divided into four:—1. Sanguine; from the supposed predominance of blood. 2. Choleric; from predominance of yellow bile. 3. Melancholic; from predominance of black bile. 4. Phlegmatic; from predominance of mucus. This arrangement, it will be seen, is founded on the supposed predominance of different fluids; but another is founded on the supposed predominance of different tissues. 1. Sanguineous; where the vascular tissue predominates. 2. Lymphatic; where the absorbent tissue predominates. 3. Athletic; where the muscular tissue predominates. 4. Nervous; where the nervous tissue predominates. 5. Moist; where the fluids predominate. 6. Dry; where the solids prevail. The French adopt this mode. Another, founded on the predominance of regions, was introduced by Thomas. 1. Cephalic. 2. Thoracic. 3. Abdominal. These may be variously combined. Charles Fox and Sir John Leslie may be mentioned as good examples of the combination of the cephalic and the abdominal. Jeffrey, of the Edinburgh Review (now Lord Jeffrey,) is an example of the union of the cephalic and the thoracic; for he is good at athletic exercises. An alderman is an example of the abdominal temperament, and a prize fighter of the thoracic.*

It is seldom that any person has one of these temperaments unmixed. A near approach to either renders him liable to particular diseases.

1. Sanguine.—If well marked, this temperament degenerates into *scrofula*. It is characterized by soft and yellow hair, blue eyes red cheeks, large veins, swelling lips, slender body, soft and clear skin, and a person altogether agreeable. The mind is active, but does not retain long the impressions received. Persons of this temperament are liable to the de-

* We should be disposed to mention Lord Brougham and Dr. Birkbeck as excellent examples of the cephalic temperament of this arrangement, and of the nervous temperament of the preceding.

position of soft tissues, such as melanosis, and to acute diseases of all kinds; which, however, are in general not obstinate.

2. Choleric.—This temperament is well exemplified in the captain of a Leith smack. The hair is red and crisp; the eyes are small and shining; the cheeks orange-coloured; the skin hard; the body square; the legs standing widely apart; and the temper irascible. It predisposes to diseases of the heart and of the liver, to aneurisms, &c.

3. Melancholic.—Well seen in Don Quixote, and a Methodist preacher. The hair is long, smooth, and straight; the eyes dark; the face long, and of a tawny colour. The body is hard, and without fat. The mind is slow, but the memory tenacious. The diseases to which this temperament predisposes are melancholia, dyspepsia, schirrus, ossification, and all those which depend on the general prevalence of hard tissues.

4. Phlegmatic.—This temperament characterizes the lowest grade of humanity. The hair is long, moist, and hanging down. The eyes are dull, and the lips thick. The face is tumid and œdematous; the skin pale and flaccid; the abdomen protuberant; the whole body large and ill-shaped; and the mind torpid. The unfortunate subjects of this temperament are liable to chronic ulcers, and to various forms of dropsy.

5. Idiosyncrasy.—This is allied to temperament. It is said by the French to be owing to the preponderance of partial tissues; such as the mucous, serous, or fibrous; whereas temperament is owing to the preponderance of universal tissues. Idiosyncrasy, according to this view, is a partial temperament, while temperament is a general idiosyncrasy.

LECTURES ON SURGERY,

BY

JOHN HUNTER, F.R.S.

DIGESTION.

Animalization begins in the stomach, and in common language is called digestion, the immediate produce of which is called chyle. In the change of food into chyle we do not see why it may not have received the living principle, for the change is such as renders it capable of

becoming alive. But it may be supposed that this process is reserved for the lungs, where the chyle is so much exposed to the air: the air may be imagined to act on it like heat on an egg, or moisture and warmth on seeds, giving a power of growth to their particles. In these cases, however, it is not the principle of life which they give; they only give life its action.

Again, blood may be supposed not to become alive till it be made into a solid, when it becomes part of our body, and loses the property of blood, and there its life is indisputable; but I am apt to believe that the living principle takes place sooner, which I imagine will appear in investigating the properties of the blood, with the many phenomena that attend it in the living body.

I have already observed that the organization of animal matter is not necessary for life, only for its actions; therefore fluidity is no objection to the blood being alive. My reasons for supposing the blood to be alive in a fluid state are the following: 1. It may be observed that it appears to carry life to every part of the body, for whenever the whole or a part is deprived of fresh blood it very soon dies. This blood, however, must be such as has undergone some change in the lungs; for if the blood did not undergo this change it would probably soon die, therefore would not be capable of keeping up the living principle in other parts. This effect arising from the want of fresh blood is so evident that it needs no illustration; I may therefore conclude that it is the only cause and support of life, the nerves having no other part in it but to produce some of the actions,—not life itself, for without this support the nerves themselves die. 2. We may observe that whilst circulating, or in useful motion, it is always found in a fluid state. Hence I think I may be allowed to say, as it is never found in a solid form in the cavity of the blood-vessels, that it has not the least tendency to become solid; that such a state is contrary to its nature. This must arise from some principle which is probably both in the blood and the vessel. The want of disposition to coagulate whilst moving in the living vessel does not arise from the motion, for in many places where the motion is extremely slow the blood remains fluid. We have instances of this in the veins of the leg, where the crural artery has been tied, in which case the blood only moves through a few small

collateral branches below, and back again by the larger veins. Now, a small quantity of blood being sent into these larger vessels, the motion in them must be next to stagnation; yet, while there is any degree of motion, the irritation of imperfection is not given; there is consciousness of its being an useful part; by which is meant that the harmony between the solids and fluids is kept up. It is often curious to see the small quantity of motion which will keep up this mutual harmony. In cases where people have been days, or even weeks, in trances, where there is not the least perceptible motion in the blood, it has retained its fluidity, because both solids and fluids retained their life, though not their actions. The want of disposition to coagulate in such situations does not arise from any property in the blood simply as animal matter, for simply as animal matter, whose alterations arise out of its composition, as fermentation, it would not vary in its effects from circumstances that do not in the least alter the nature of the compound.

Dead animal matter acts on the living body as any other foreign or extraneous matter; therefore, the blood being in perfect harmony with the living principles of the solids when both are in perfect health, is a presumption that the blood is alive. However, this argument is not conclusive, for we find heterogeneous parts in the blood, which do not destroy this harmony; most probably those heterogeneous bodies are introduced simply as stimulants to the living principle, as extraneous objects are to the sensitive.

This harmony of the blood with the solids is more observable in some parts than others. The parts with which it is in the greatest harmony are the vessels; this is evident from its retaining its fluidity longer in contact with them without motion than in any other part of the body, though equally enclosed in living parts.

All the diseases which act on the solids act on the blood, causing it to effect those changes which arise spontaneously from rest out of the body; so that blood is as capable of diseased actions as the solids are. If the blood did not change in the diseased states of the solids, it would lose the natural harmony I have been speaking of. This change is according to the state of the solids, which shows the intimate connexion between the two; it is not a primary diseased alteration of the fluids,

but a consent with the diseased disposition of the solids.

On the other hand, the solids are affected by diseases of the blood: I even suspect death in the blood can take place independently of the solids; but the death of the solids will soon follow.

The blood when at rest has a disposition to separate into several parts, viz. coagulable lymph, red particles, and serum; the red part being retained in the coagulable matter, and the serum squeezed out in the act of coagulation. This disposition in one of the parts to coagulate when at rest, from whence the above changes are produced, is more or less strong, according to circumstances.

This property of the blood deserves particular attention, as it throws more light on its nature than any point of view in which it can be considered, it being spontaneous and natural. It is by this change that the solids are formed, and it seems to me so important that I think it almost the only thing necessary to be considered more fully; indeed the power of coagulation in the blood throws so much light on the nature of a disease, so far as the blood is concerned, that it is almost the only part we have recourse to in the examination of the blood after bleeding, when we look to see whether or not the blood is buffy, that is, whether there has been a disposition for the red globules to sink faster in such blood; or rather, perhaps, that from such blood being longer in coagulating, the red globules have time to sink to the bottom, and leave the coagulable lymph atop free from red globules, and this causes the buff of the blood. It is by this coagulation also that we perceive whether the blood is cupped or not, that is, whether the coagulum draws together and its edges rise; and then we say that the blood is not only inflammatory, but highly so, showing great strength in the constitution: if, on the other hand, it lies flat in the cup, and makes an even uniform surface, we know it is rather loose in its texture, although it may be still buffy, which shows that the powers of the constitution are weak.

The red globules abstracted, or the red blood abstracted from the other parts, need scarcely be considered, as they hardly explain any thing.

The serum also explains but very little; there may be more or less of it than common, but in itself it explains very little.

The power of coagulating in the blood

is greater when out of the circulation and exposed to common air, even more than when extravasated in some cavities of the body, the necessity or use of which is evident, for by this it becomes more effectual in stopping extravasation. A striking instance of this kind happened in the crural artery of a boar. I cut it through and allowed it to bleed; but before the animal became weak, or, at least, had the appearance of weakness, the bleeding became less and less, till at last it stopped. On examining the artery, it was found to have a quantity of coagulated blood opposing and surrounding its cut end like a mop, through which the blood could not pass.

This power of coagulation, especially when exposed, enables the blood to unite external wounds more readily, and of course preserves the living principle better, and keeps the internal parts from exposure in many wounds which otherwise would become external; by this means they are united by the first intention.

In all inflammatory dispositions in the solids, whether general or local, the blood has an increased disposition to separate into its component parts, the red globules become less uniformly diffused, and their attraction to one another becomes stronger, so that the blood when out of the vessels soon becomes cloudy or muddy, and dusky in its colour, and when spread over any surface it appears mottled, the red blood attracting itself and forming spots of red. This is so evident in many cases that it is hardly necessary to wait till the whole coagulates to form a judgment of it. I think I can say when the blood is coming from the vessel, by its appearance in the stream, whether it will be sily or not. When the blood has not an inflammatory disposition, the stream has a degree of uniformity and transparency in its appearance: but it is only an eye accustomed to it that can make this distinction.

If the inflammatory disposition of the solids arises from fever, this disposition in the blood is universal. If there is universal inflammatory disposition from some local irritation, the blood is still universally affected. But if the inflammation is local, and the constitution is not affected, the disposition in the blood is not universal: how far there is local inflammatory disposition of the blood I do not know, but there is reason, however, to suspect it, from the ready union of parts

under inflammation. If the blood does become inflamed in passing through an inflamed part, we must suppose that it immediately loses that disposition when it meets with parts in perfect health.

These properties, namely, increased disposition to separate, and a disposition to become a firmer solid, always show increased disposition for action in the living principle, and also, most probably, increased power. It is one of the signs of strength of the living powers, although the materials for action are weak.

The use of this change in the blood is evident, since it is made fitter for uniting parts by this means; and it is from this disposition that the blood retains its living principle sufficiently long till union takes place. Unless the stimulus of necessity for coagulation is given by the solids, the extravasated blood will not coagulate, it will only act as an extraneous body, which often happens where union is unnecessary, improper, or hurtful, as in cases of contusions, where the blood remains fluid in the cellular membrane.

This disposition to coagulate when out of the vessels, or when retained in them without motion till the consciousness of the use of motion, and of course fluidity, is lost, is one of the effects of the life of the blood.

I have used the word *consciousness* because we have no language suitable to all my views of the animal œconomy, and to coin words would not answer the purpose, because then I must have a dictionary of my own. I have not a word for expressing the cause of those actions which take place in the body, as if it was conscious that such and such things were going to take place. There are actions in the body which come the nearest to consciousness of the mind of any thing that I can conceive, and therefore I make use of this word; but it is commonly applied by philosophers only to the mind.

Coagulation is a species of attraction arising out of this irritation. It may be considered as a species of generation, for it is the first action or establishment of a power of action within itself, so as to form itself into muscular fibres, the only powers in an animal: these, again, with other parts, form organs to act on the materials from which they arose, for their own support.

I will relate a case in proof of most of the arguments which I have employed respecting the life of the blood. It is one of many.

A man came to St. George's Hospital who had a hydrocele, for which he was tapped with a lancet. The water was clear serum: when this was evacuated, the testicle to the feel was found to be larger than natural. About a month after, the tunica vaginalis became as full as before: the radical cure was now determined on, the tunica vaginalis was slit up its whole length, and the fluid, which was now bloody, was evacuated. The testicle, on being exposed, was found larger than natural, and was extracted. On the body of the testicle, and nearly in the direction of its long axis, and opposite to the orifice in the sac made by the lancet when the water was first evacuated, lay a coagulum of blood, dark in colour, almost like a leech, when that animal is shortened, about two inches long, and of the thickness of a common-sized little finger. In the angles between the epididymis and body of the testicle lay another coagulum, adhering in some places to the epididymis, in other parts loose to the body: it was attached only at one end. The adhesions of the large coagulum to the body of the testicle were firm, although it would admit of separation. This was made at one end, when fibres were plainly seen running from the testicle to the coagulum. The adhesion of the small coagulum was in many parts still firmer. All over the tunica vaginalis there were a great many vessels full of blood, and in many parts coagula of blood like extravasation. In this state I had a drawing made of it, and a small part magnified, to show the vessels and the dots of extravasation as they then appeared. By being put into water all these vessels and dots disappeared, and the parts became white. I then injected the testicle by the spermatic artery, which succeeded extremely well. On examining the part, I observed the following appearances. The surface of the testicle and tunica vaginalis had resumed the former appearance, only with this difference, that the injection was of a lighter red than the blood to the naked eye, and much more so to a small magnifier. The vessels on the surface were very distinct, and the dots, where the extravasation of injection was as if there had been extravasation of blood. The coagulum on the tunica vaginalis now appeared vascular; the surface of the adhesion, for about one twentieth of an inch, was injected and extremely full of distinct vessels. The smaller coagulum was in-

jected in many places through and through its whole substance, in the other only for a little way.

If it should be asked, how came those coagula there? The answer is, the blood from the wound made by the lancet in the tunica vaginalis passed into the cavity, and then coagulated on the testicle directly opposite to the wound, and a small quantity of the blood which got to down the chink between the testis and epididymis coagulated there also. That this is the most probable way of accounting for it is, I think, strengthened by another case, where the tunica vaginalis was found adhering to the testicle, when performing the radical cure, at the very part where he had before been tapped. In half a year probably this coagulum would have become wholly vascular, and probably in a little longer time the whole would have been taken away; because, being vascular, it would have had absorbents, which would have taken it all, as a useless part, into the constitution.

The tunica vaginalis filling again so rapidly in this case was perhaps the reason why it did not adhere to the coagulum on the other side, so as to produce a union between the two parts.

Quere, For what purpose did this coagulum become vascular? for no visible purpose could be answered by it, as absorption, we may suppose, might have taken place as easily in a coagulum as in the cellular membrane. But perhaps absorption not going on here was the cause of the collection of water; and adhesive inflammation evidently took place here that it might be able to absorb itself.

Thus, then, the materials of which the blood is composed are joined with the living principle: in consequence of which the blood, if properly disposed, is capable, when extravasated, of forming itself spontaneously into parts fit for motion, and for performing all the offices of any part of the living whole, successively receiving the stimulus of nature from the surrounding parts to form itself into a similar part, as bone, cartilage, &c.

In many diseases not inflammatory, namely, those called putrid, where the solids have a tendency to fall into those changes natural to animal matter deprived of its preserving principle, the blood has no disposition to coagulate, nor the solids any power of raising inflammation, both having taken on the same disposition. In such a disease both the principle and power are diminished, so that

life is hardly able to preserve the matter from falling into its natural changes, though it has still a disposition to keep the vital parts or body moving.

Many kinds of death as well as putrid diseases produce this effect on the blood; an instance of which was met with in a gentleman, who being in perfect health, died instantaneously from passion, this having been so violent as to produce death in every part at once, and his blood did not coagulate.

A healthy woman was taken in labour of her fourth child. As the child was coming into the world the woman died almost instantly. On opening the body next day, there appeared no cause for death whatever, every part being natural and sound; but the blood was in a fluid state, nor did it coagulate on being exposed.

A soldier, a healthy young man, confined for desertion, received a blow on the pit of his stomach from one of his comrades, from which he dropped down and died almost instantly. On opening the body, no preternatural appearance was observed, but the blood was in a perfectly fluid state, and did not coagulate when taken out of the vessels and exposed a considerable time.

In animals struck dead by lightning the blood does not coagulate nor the muscles contract, both being killed at once.

There are other instances. Two deer were hunted to death. On opening them the blood was fluid, only a little thickened, and the muscles were not rigid, as we find them, where they are capable of acting, from the stimulus of death. In both cases the life of the solids and of the blood was destroyed at the same time and at once.

The observation that animals hunted to death are tenderer than those killed by other means is not uncommon.

There is a natural action of the living body which destroys the life of the blood in the act of extravasation; this is the discharge of the menses in women. If that discharge is natural and healthy, the blood does not coagulate; but, on the other hand, if the extravasation is not a healthy one, the blood coagulates as it is extravasated, and comes away in clots. This perhaps is best demonstrated in cases where the hymen is imperforate and the menses are accumulated. This observation leads us to understand something of the nature of the menses; for depend on it, where a woman has her

menses come away in clots, it is not a natural but a diseased discharge.*

To prove that the blood and the solids correspond very much in their actions of death, we shall only generally observe, that when an animal dies in the common way, it is by the vital actions being first destroyed; but life still exists, for the muscles contract and the blood coagulates. But if we destroy life instantaneously, or along with the vital actions, then the muscles will not act, and the blood will remain fluid.

These changes in the blood, which appear spontaneous, are not really so; they arise from irritation in the blood itself as much as any actions in the solids. This irritation excites the natural action of the blood, which produces these effects and all the properties we see the blood possesses in either a healthy or diseased state.

We cannot suppose the blood has a power of communicating sensations, as it cannot have nerves; its living powers are therefore those of simple life, and it is similar in that respect to the solids of many animals.

As sensation is a principle superadded, and intended to convey fixed intelligence it is unnecessary for a moving part to have it; but when it becomes a fixed and solid part it opens a communication with the mind.

Thus far I have endeavoured to show that the blood is as much endowed with life as the solids are; and the only difference between the two is that the solids have construction, called organization, producing considerable visible effects, while the blood, not having this construction, does not produce these visible effects. The truth of this theory will appear more evident in treating of the diseases of the animal body.

* It is now the universal opinion of physiologists, that the menstrual fluid is a secretion, neither venous or arterial blood, and does not coagulate in its normal condition. The uterus is congested before and during menstruation, and on concussion may discharge blood with the menstrual fluid. This is a disease as stated in the text. —Ed.

AN ADDRESS

DELIVERED TO THE MEMBERS OF THE

WORCESTERSHIRE

NATURAL HISTORY SOCIETY,

ON THE OPENING OF THE

WORCESTERSHIRE MUSEUM,

SEPTEMBER 15, 1836.

BY CHARLES HASTINGS, M.D. F.G.S.

(Continued from page 196.)

We may indeed here take very high ground, and say to those babblers who talk of the insignificance of the labours of the naturalist, "Can *that* be an object unworthy the investigation of the most gifted mind, to which the penetrating genius of an Aristotle thought it not unbecoming to devote its best energies?"

Can any misplaced sarcasm which would represent this study as frivolous, produce in any reflecting mind an insensibility to the unity and grandeur of nature, to the matchless structure of sublunary bodies, and to the beautiful laws of organic life, which must clearly develop themselves to all those who study natural history, according to the rules of the inductive philosophy, as laid down by the immortal Bacon?

Can any unprejudiced mind fail to be interested in the cause of natural science, when he reflects that it was this very subject which called forth all the energies of the great Linnæus, who justly thought that in the temple of Fame a niche would be allotted to patient investigation, and who consequently employed the powers of a methodical and sagacious mind to the classification of organic bodies?

Should not the scoffer at natural history, who fancies he desecrates in the minute details in which the naturalist is engaged an opportunity of shooting forth the sallies of his wit, recollect that these details are capable of being adorned by persuasive oratory, and that the illustrious Buffon at once threw around natural history the mantle of poetry and philosophy, and by his animated and picturesque descriptions, his bold and original views, and his rich and powerful eloquence, intrenched it in public estimation?

Finally, should not all those who neglect or undervalue this delightful study

look to the portraiture of the great, the wise, the philosophic Cuvier, who was an indefatigable collector, a judicious classifier, and a skilful anatomist—who, as a lecturer in the college of France, shone as a successful teacher, and enchanted crowded audiences by the magic of his eloquence—who was also one of the most learned, and eloquent, and powerful writers of his day?—whose unwearied research, lucid arrangement, and pleasing, perspicuous, and nervous style, placed him above the philosophical naturalists of every age—whose discoveries in fossil geology have raised him to the highest distinction, and given birth to new trains of research, which are fast disclosing to us the structure of our planet, and the nature of the convulsions with which it has been so often shaken. By looking at natural history as surrounded by the halo of these gifted spirits, minds of the highest bearing will be allured to its cultivation, and yet at the same time it will be found accessible and instructive to every class of inquirers; and thus become the support and handmaid of natural religion.

But it is almost impossible for the student of natural science to make any progress without finding, at every step he advances, proofs of design in the creation, and it is not one of the least of the advantages attending such pursuits, that they are continually revealing to the candid inquirer after truth, the nice adaptation of the instruments employed in the universe, by the Creator, to effect their intended purposes. Thus the office of natural history is to expound the works of Omnipotence, and it becomes from that very circumstance one of the most dignified that can employ the human mind. It seems, in fact, to be that peculiar study which is, above all others, most designed to bring man into communion with his Maker. Hence it is manifest how intimately the study of nature is connected with the truths of religion. Every philosophic argument which can be drawn from the material world in corroboration of the books of Scripture, will tend to bring those who doubt to investigate their pages more closely; while those who already believe their divine inspiration will have that belief strengthened and confirmed, rejoicing that sound philosophy bears witness to those truths which they feel to be immutable.

The striking and instructive nature of the terrestrial adaptations to the vegetable and animal world have been dwelt upon with singular felicity by the pious and

philosophic Whewell, in his admirable *Bridgewater Treatise*, who observes, "that the simple circumstance of the rise of the sap in vegetables could not be effected without a number of particulars being taken into account, the neglect of any one of which would be fatal to the success of this process."

The capability which man and animals enjoy of locomotion is another instance of the adaptation of this earth to the organized beings on its surface. If, for instance, there were an alteration of the gravity of the earth, such a change might be produced in the relation of the animal kingdom to this planet, that the lightness of the fawn, the speed of the hare, the spring of the tiger, could no longer exist with the muscular powers now possessed by those animals; and the motions of man, which are now so easy that they are almost effected without our observation, might become a labour slower and more painful than those of the sloth. I know, however, of no natural phenomena more calculated to awaken admiration and reverence than those complicated adjustments which are necessary to make the atmosphere answer the numerous purposes for which Providence formed it. It seems impossible to suppose that its various properties were so bestowed and so combined any otherwise than by a beneficent and intelligent being, able and willing to diffuse organization, life, health, and enjoyment through all parts of the visible world; possessing a fertility of means which no multiplicity of objects could exhaust, and a discrimination of consequences which no complication of conditions could embarrass.

" 'Tis surely God,
Whose unrelenting energy pervades,
Adjusts, sustains, and agitates the whole;
He ceaseless works alone, and yet alone
Seems not to work, yet with such perfection framed
Is this complex stupendous scheme of things."

There is another department of natural history full of interest, and worthy of profound meditation, to which I must invite your attention, as being peculiarly deserving cultivation; and yet, strange to say, although apparently of great importance to every individual, it does not receive the deserved regard: for of all subjects of scientific interest, men in general seem to have the weakest curiosity as to the structure and functions of their own body. It is by no means uncommon to meet with men of unwearied research, who are ready to devote themselves with energy to the study of nature—who will ascend mountains with wonder and de-

light—who will visit with amazement the rushing of mighty waters over stupendous rocks—who can tell the number of the known stars—and who are acquainted with the laws that regulate the flux and reflux of the sea: but you will find these very persons lamentably ignorant of the laws by which their own frame is governed, and of the marvellous results which are every hour produced by them. The structure, indeed, of man's body actually astonishes us with the wondrous excellence of its delicate conformation, for it is in perfect accordance with the most exact mechanical principles. If we examine the heart and blood vessels, through which the vital fluid circulates, we find a perfect hydraulic machine, the heart being a powerful engine, by which the blood is propelled to the extreme parts of the body; the lungs constitute a most inimitable pneumatic apparatus; the beautiful membranes and transparent humours of the eye form an admirable optical instrument; and the organ of hearing is constructed on the most approved principles of acoustics. Thus, from this very brief survey of our own bodies, we must be elevated to a sense of admiration of the creative wisdom of the Omnipotent Architect of the universe, in whom "we live, and move, and have our being." Dr. Arbuthnot thus beautifully illustrates the construction of the human body:—

"Am I but what I seem, mere flesh and blood,
A branching channel and a mazy flood?
The purple stream that through my vessel glides,
Dull and unconscious flows like common tides;
The pipes through which the circling juices stray,
Are not that thinking I no more than they.
This frame compacted with transcendent skill
Of moving joints, obedient to my will,
Nurs'd from the fruitful glebe, like yonder tree,
Waxes and Wastes, I call it mine, not me,
New matter still the mould'ring mass sustains;
The mansion *Changed*, the tenant *still remains*;
And from the fleeting stream repaired by food,
Distinct as is the swimmer from the flood."

But, after all, the mind is the standard of the man; and beautiful and striking as are the mechanical adaptations now referred to, they are far inferior to those which are subservient to our mental faculties. The brain is the organ of the immaterial principle, where the mind takes up her residence, and holds communication with material things. This organ being exceedingly tender and susceptible of injury, the slightest local compression disturbing its action, it was necessary that it should be well protected from external violence. What could have been so well calculated for the defence of such an organ as the skull?

Man could never have formed a structure so well calculated for the purpose it serves: the Divine Architect could alone effect it. The poet forcibly conveys this sentiment when he says,

"Observe this skull from out the scatter'd heaps;
Is this a temple where a God may dwell?
Look on its broken arch, its ruin'd wall,
Its chambers desolate and portals foul.
Yet this was once Ambition's airy hall,
The dome of thought, the palace of the soul:
Behold through each lack-lustre eyeless hole,
The gay recesses of wisdom and of wit,
And passions hot that never brook control.
Can all saint, sage, or sophist ever writ
People this lonely tower, this tenebrous rift?"

The study of natural history, so far as it unfolds the nice adaptation of the structure and functions of the human body to the objects by which it is surrounded, and which are continually affecting it, should receive encouragement from the statesman and legislator, because it is only by the importance of these subjects being deeply impressed upon the minds of the community that we can hope to see those ameliorations effected in the state of the public health which advancing civilization seems capable of realizing. Every day have we in our medical capacity to deplore the ignorance which prevails, in every class of society, of the common organic laws which regulate the animal economy, and the direful effects resulting from whose infringement might be obviated by a diffusion of a general knowledge of them. Doubtless when the study of our common nature shall have assumed its station among the pursuits which no person of education can have neglected without discredit, these evils will in some measure be redressed.

In connexion with this subject, it may not be inappropriate to mention that in towns and cities, where large masses of people are crowded together, the growing desire to foster, by public support, establishments of baths for general resort, and gardens where all classes of the inhabitants may freely inhale the breath of heaven, should be actively encouraged by all true philanthropists; and those enlightened individuals, who have stood prominently forward in this beautiful city as the advocates of improvements in our social and moral condition, should not rest satisfied until they have added these important improvements to those which have of late years conduced so much to its credit and renown.

Need I say a word to my medical friends, in order to convince them that it is incumbent on every cultivator of the

healing art to exert himself in his sphere of life, and to do all in his power to promote the objects we are now met to forward. I may call to their recollection that from the animal, vegetable, and mineral kingdoms are produced nearly all the remedies that employed in the treatment of disease. I may also remark how necessary it is for them to study the laws which govern the atmosphere; since, independent of the effects of those vicissitudes to which the human body is daily exposed, there are certain occult conditions of this element which have a most undoubted effect in producing the most devastating diseases that afflict mankind; and this induced Hippocrates to say, that to discern with precision the constitution of the seasons and the diseases that attend them is the greatest excellence in the art of physic. We have moreover in modern times a remarkable instance of the happy results which ensue to medicine, and consequently to mankind, from physicians attending to the study of natural history; for to this probably we are indebted for the invaluable discovery of vaccination. Had not Jenner, who practised medicine in the country, been engaged in these pursuits, and continually watching the daily operation of the laws of nature, the fact of a certain disease among cattle being communicated to the persons who milked them would not have been considered of much importance, and would certainly have never been so philosophically applied as to produce a most important chain of reasoning, whereby conclusions were established and a discovery made by which the ravages of small-pox, one of the direst scourges of the human race, have been greatly mitigated.

I have thus enlarged on the utility of natural history, and hope I have succeeded in demonstrating the fallacy of the notion held by some persons, that natural history may be very well as an amusement, which serves to guile away an idle hour, but that it is not deserving further.

If, however, the claims of natural history upon our attention, as being necessary to impress upon us a due consideration of our physical condition, relatively to the world around us, were not so strong as they undoubtedly are; still there are in these pursuits so many sources of intellectual gratification, that the mind must be dead indeed to all the better feelings of humanity, if it were incapable of appreciating them. The lonely wanderer

In the country can attest how greatly the beauty and wonders of creation are heightened by an insight into vegetable organization; for who is there that does not admire the beauty and variety of flowers, of fruits, of shrubs, of plants, of trees, nay, even of the very grasses which we tread beneath our feet. The variety and the beauty of flowers are endless and inexhaustible, and even the commonest hedge-flowers are of hues so beautiful, and structures so exquisitely delicate, that we cannot avoid a feeling of ignorant wonder when we regard what appears a prodigality of loveliness; and if we proceed further, and examine the interior structure of these productions, and are shown by the microscope what an elaborate preparation of vessels, and tubes, and cavities they contain, we do not admire their beauty less, but we admire the power and wisdom which created them more, and are constrained to say,

"Oh, good beyond compare!
 If thus thy meaner works are fair;
 If thus thy virtues gild the span
 Of ruin'd earth and sinful man;
 How glorious must that mansion be
 Where thy redeem'd shall live with thee!"

The study of nature can never be so well or so delightfully prosecuted as in her own haunts, remote from cities. Hence it is that no pursuits can be better adapted for a country life. We are then, as it were, in the boundless temple of nature, and we explore truth in all its various recesses. There are many, however, who cannot enjoy the recreations of the country naturalist, or gratify their love of nature by contemplating her works in the field; but "Natural History," says Mr. Swainson, "has this peculiar advantage, that it can be prosecuted in one shape or other by almost every body, and under every ordinary circumstance. Of all sciences, it is that which requires, in most of its departments, the fewest materials; it is as much within the reach of the cottager as the professor; or rather we should say, it embraces questions which can be solved by the former just as well, and frequently much better than by the latter. If, as is generally the case, the amateur confines himself to the productions of his own country, three or four elementary books, and as many implements of chase, are all that is necessary. His own exertions will procure him a collection; and he thus furnishes himself with additional materials for study; but even these are not absolutely essential. The appearances of Nature can be investigated and

recorded without acquiring the technicality of scientific language; nor for such purposes are collections and museums indispensable. A fund of interesting anecdotes of our native animals may be collected by an attentive observer, who is nevertheless ignorant of their scientific names. White, of Selbourne is a striking example of this truth. His letters show a very confined knowledge even of the imperfect arrangements of the period in which he wrote; yet how delightful are his observations! The fact is he looked to nature and simply recorded what he saw."

3. In pursuance of my proposed plan, I will lastly succinctly trace the progress of Natural History from its earliest rude and barren state to its present advanced and promising condition, by shortly laying before you some account of its most successful labourers.

One of the greatest pleasures we experience in the pursuit of knowledge is in becoming acquainted with the thoughts, feelings, pursuits, and labourious investigations of the illustrious dead, and no less illustrious living authors. If this be true of the general pursuit of knowledge, it is no less so of the particular branch of it to which the labours of this Society are more especially devoted.

Natural History existed in the earliest states of society of which we have any record. We find sufficient notices of it in the Old Testament to convince us that, in that early period of the world, the productions of nature were studied with great interest. Indeed it is evident that Solomon, the wise king of Israel, paid no small attention to zoology and botany; for it is said of him, that "he spake of trees, from the cedar-tree that is in Lebanon, even unto the hyssop that springeth out of the wall: he spake also of beasts, and of fowl, and of creeping things, and of fishes." (1 Kings, iv. 33.) But admitting as we do, that Natural History attracted attention in very early times, we must concede to Aristotle the merit of having first established it on a scientific basis. He flourished about 384 years before the birth of Christ: and medicine can fortunately claim him as one of her sons, for his father was a physician. He was a man of gigantic powers of mind, and he employed them in the study of philosophy, poetry, rhetoric, and law. Like many of the philosophers of antiquity, who lived at a time when the great body of the community was unable to appreciate the true value of

knowledge, he was persecuted by an ignorant populace. During the life of Alexander the Great, who was his friend, he was treated with respect; but after his death he was obliged to withdraw from Athens, and is said to have shortly afterwards died of vexation and regret. An elegant writer, in speaking of the Stagyræ's claim to consideration as a naturalist, says, "had this extraordinary man left us no other memorial of his talents than his researches in zoology, he would still be looked upon as one of the greatest philosophers of ancient Greece, even in its highest and brightest age. But when it is considered that his eloquence, and his depth of thought, gave laws to orators and poets—that he was almost equally great in moral as in physical science, and that no department of human learning escaped his research, or was left unilluminated by his genius, we might be almost tempted to think, that the powers of the human mind in these latter days had retrograded, and that originality of thought and of philosophic combination, existed in a far higher degree among the heathen philosophers than in those who followed them." It seems unnecessary to make any further observation on the works of this great genius of antiquity, and we may pass on from the Greeks to the Romans, among whom Natural History made no progress. Pliny is the only name that can bear any comparison with Aristotle. He lived in the reigns of Vespasian and Titus, and wrote a Natural History in thirty-seven books. In intellectual power he was greatly inferior to Aristotle, and was incapable of those enlarged general views which characterize the works of the Grecian sage. Pliny, moreover, too readily lent his belief to the marvellous, and by thus giving proof of a mind not of the first order, the fact is explained, that his works do not so much show originality of genius, but may be considered as a good compilation of the knowledge which he had derived from studying what had been done by Aristotle. After the time of Pliny, Natural History declined under the Romans, as it degenerated into a system of tales and prodigies, undeserving the name of a science.

A long night of intellectual darkness extending over a period of nearly four-hundred years, followed the decline and fall of Roman greatness; and it was not till after the revival of learning in the sixteenth century that any thing worthy of remark has been handed down to

us. Soon after the revival of learning two most laborious writers in zoology appeared, Aldrovandus and Gesner; they both adopted Aristotle's method.

But it were unjust to the memory of one of the greatest of mankind not to mention that, for the subsequent successful advancement of Natural History, as well as for that of almost every other branch of useful knowledge, we are indebted to the rules of induction laid down by our immortal countryman, Bacon.

"Hapless in his choice,
Unfit to stand the civil storm of state,
And through the smooth barbarity of courts,
With firm but pliant virtue, forward still
To urge his course, him for the studious shade
Kind nature formed, deep, comprehensive, clear,
Exact, and elegant; in one rich soul,
Plato, the Stagyræ, and Tully joined.
The great deliverer; who from the gloom
Of cloistered monks, and jargon-teaching schools,
Led forth the true philosophy, there long
Held in the magic chains of words and forms,
And definitions void; he led her forth,
Daughter of heaven; that slow-ascending still,
Investigating sure the chain of things,
With radiant finger points to heaven again.

He complains that, before his time, the greatest part of the study of philosophers was consumed in moral philosophy, which was as the heathen divinity. And in ancient times a great part of the best wits betook themselves to law pleadings and causes of estate; specially in the time of the greatness of the Romans, who, by reason of their large empire, needed the service of all their able men for civil business, since which time natural science was never any profession nor ever possessed any whole man, except perchance some monk in a cloister or some gentleman in the country, and that very rarely.

It was not that Bacon himself added so much to the stock of our knowledge of Natural History as that by the rules of philosophizing which he imparted, his successors were enabled to make great progress. His publications on this subject are to be found in the last part of his Organum, and nothing can exceed the modesty with which he speaks of what he had done. He says, it is a thing exceedingly little in quantity, like a grain of mustard-seed, but yet a pledge of those things which, God willing, may ensue.

After Bacon, followed in our country Willughby and Ray, the successful result of whose combined labours may in great measure be attributed to their having imbibed the true spirit of the inductive philosophy, and thus presented as it were to us the first fruits that arose from this mode of cultivating this field of knowledge.

A PRACTICAL VIEW
OF
LITHOTRITY:
WITH REMARKS ON
THE LATERAL OPERATION OF
LITHOTOMY.

BY MR. ASTON KEY.

(Continued from page 201.)

My first acquaintance with lithotrity did not prepossess me much in its favour. Many years ago, I obtained, through a friend at Paris, the three-branch instrument invented by Civiale, and constructed by Charrière, for the purpose of drilling the stone. The difficulty that I experienced in using it on the living subject, and the incomplete manner in which it crushed the shells of the stone after excavating its interior, induced me, after two or three unsuccessful trials, to abandon the operation, as imperfect.

A fresh impulse seemed, however, to be given to lithotrity, and many of the imperfections of Civiale's instrument to be obviated by the improvements suggested by Heurteloup. Soon after his arrival in this country, I invited him to lecture to the Surgical Class of Guy's Hospital; in order that the gentlemen who were studying there might, through him, be made acquainted with an art that I but very imperfectly understood. Baron Heurteloup politely accepted the invitation; and gave a full explanation of the instruments that he used, and of the advantages they possessed over those generally employed. The lecture did not embrace the general principles of the operation of lithotrity, but was confined to the mechanism of the instruments which he had invented. The ingenuity of these instruments, and the dexterity of the operator, were alike the subjects of admiration; but instead of simplifying the operation, they appeared to render it more complicated, by the multiplication of appliances. Each presented a new difficulty: so that I resolved to abandon all idea of lithotrity, until it became less complex, in its performance, and in the instruments required. It reminded me, indeed of the apparatus major formerly used in lithotomy; and I accordingly did not despair of seeing the "brise coq," the "vergule," and the other intricate machinery, superseded by a simple but effi-

cient instrument; and as the apparatus major has been by the operation of Frère Jacques.

Accident soon led to the discovery of an instrument, as simple in its application as the former had been complicated, and possessing the additional merit of being more effective in accomplishing its purpose. Report attributes the idea of percussion to Baron Heurteloup having been compelled to finish an operation by striking the drill of his instrument, the bow being rendered unserviceable by an accident. His application to Mr. Weiss on the subject brought to light an instrument constructed, long previously, for the purpose of crushing a stone, and resembling in shape a catheter with a shortened beak. This instrument furnished the idea of the present lithotrite: it has undergone several modifications and improvements; but, in principle, the instrument now used is much the same as that originally constructed by Weiss.

Not long after the introduction of percussion into lithotrity, I had an opportunity of witnessing an operation by Baron Heurteloup, in which he used the hammer: the simplicity of the operation, the rapidity of its performance, and the apparent security with which the hammer was struck without giving pain to the patient, presented a favourable contrast to the slow and uncertain operation of the drill;—not the least remarkable part of the performance being the almost entire unconsciousness which the patient evinced of the instrument being struck; as the vice which held the percussor transmitted the vibrations into the bed on which he lay; so that the bladder scarcely felt the slightest shock when the hammer was used. In seizing the stone, the superiority of this over the three-branch instrument was evident. I left the baron's house impressed with his dexterity, as well as with the great improvement which the change in the instrument had wrought.

My conviction, that lithotrity would, in the course of time, supersede lithotomy, in many cases in which the latter was employed, was confirmed by the new features which percussion had given to the operation, and by the advantages it possessed over the former mode of crushing the stone by the drill, in the subsequent steps of breaking up the fragments. I had always had misgivings as to the efficacy of the "brise coq." Though ingeniously contrived for the purpose of crushing the fragments, which the three-

branch instrument could not seize, and well adapted for this purpose when once it got them within its grasp, it did not seem well devised for seizing them. It was straight; and opened, by the divergence of its two blades, like a pair of forceps; and therefore could only be brought to act within a very limited sphere in the bladder. The difficulty of seizing small fragments with such an instrument must have been considerable, and the consequent risk of leaving small pieces of stone in the bladder great. This difficulty—and a main one it was in my view—was wholly obviated by the percussor, which could be brought to seize and to act nearly as well upon the scattered fragments as on the entire calculus. This seemed to be no slight improvement, in an operation, one principal danger of which was, that of leaving fragments in the bladder as nuclei for future stones.

From this time I began to study lithotripsy, in the hope that it might be made available to the general surgeon, as an occasional substitute for the knife. With this view, I endeavoured to overcome the difficulties of using the instrument; to ascertain in what the dangers of the operation consisted; and to acquire, by frequent practice, that facility and readiness in manipulation, which lithotripsy requires. My expectations have been fully realized. Since commencing the practice of lithotripsy, I found that more than half the number of adults who have come under my care have been fit subjects for the operation: and that, in the majority of persons afflicted with calculus, it has decided advantages over lithotomy. One, among the principal advantages which lithotripsy has conferred upon surgery, is the early application which patients are induced to make for the relief of their disorder.

Formerly, it was a matter of notoriety to all surgeons, that patients labouring, or suspected to labour, under calculous disorders entertained a feeling of dread, almost amounting to horror, at the idea of having a stone in the bladder. The disease was associated in their minds with a most painful and dangerous operation, that must be had recourse to, as a last remedy, when palliative measures failed to afford relief to their sufferings. The dangers and sufferings of lithotomy, magnified as they were by the patient's fears, often deterred him from applying for medical assistance, when the pains of stone first came upon him, by the dread

of having his worst fears confirmed. Even if the presence of a stone in his bladder were ascertained, it was, in too many instances, allowed to remain undisturbed, in the vain expectation that it might not increase in size, and that the severity of pain might continue to be mitigated by the medicine that so often had been found to assuage his pangs. The operation was thus procrastinated, until the stone acquired a large size—often until the bladder had become diseased, and the patient's health undermined by protracted sufferings. The knife, it was thought, could be at any time employed; and its use was too frequently deferred till it became impracticable.

The change that has taken place in the feelings of persons who are troubled with calculus is attributable to lithotripsy. It is one, certainly 'not the least, among the benefits conferred on such sufferers by the introduction of this operation. They no longer entertain the dread of their symptoms depending on the presence of a stone: and when the stone is found, they cheerfully make up their minds to undergo an operation, which they regard as free from danger, and nearly so from pain. I have known a patient, and more than one, to be pleased with the discovery of a stone in the bladder; convinced, as he expressed it, that he could look for an easy cure from the new operation. The exaggerated statements of the advantages of lithotripsy have thus not been attended with good: they have been the means of inducing persons to come forward to obtain relief, when the disease was incipient, and the stone small.

Nor has it been without its influence on the surgeon. Formerly, when a patient first consulted him for symptoms of dysuria followed by pain, he was content to palliate the malady by sedative and alkaline medicines, regardless whether they were caused by prostatic affection, stone, or any other local disturbance. The use of the sound was deferred: that could be used at any time: and, usually, it was first introduced into the bladder when the patient's sufferings had become severe and protracted. He knew that the patient would not easily be brought to submit to the knife; and that to ascertain the existence of the stone in the early stage of the disease was a matter of no great moment. The operation of sounding was also conducted in a slovenly manner. If the stone were not discovered when small, it would be when large; and no advantage was gained by operating

in the early stage. Now, the surgeon examines the bladder with great care: knowing the importance of discovering the calculus at the earliest period, he no longer leaves its existence a matter of doubt, but proceeds at once to examine the bladder, and determines its presence; or, by a skilful searching of every part of the viscus, ascertains that a stone does not exist. In the present state of the art, a surgeon would be highly culpable who did not decide, by the sound, whether the symptoms for which he was consulted arose from calculus, or from some other cause.

The early symptoms of the disease are thus watched with more jealousy on the part of the surgeon, and are not so scrupulously concealed by the patient. The advantages of an early knowledge of the existence of a stone, and of prompt measures for its removal, are known to both. The result of this is, that patients apply for advice when the stone is small, the bladder uninjured by its presence, and the kidneys free from disease. In three persons out of four who apply for advice for symptoms of calculus, the size of the stone and the conditions of the viscus render lithotripsy an easy and a safe operation. Within the last three or four years, I have remarked the very early application that patients make for advice, and the small size of the stone when first discovered, compared with those of former years. In private practice, I have not extracted, by either operation, a calculus larger than a good-sized mulberry; except in three cases, in one of which the stone was of unusually rapid formation. It rarely acquires any considerable size before the symptoms of its presence become sufficiently urgent to induce the patient to seek for assistance: often, when it is so small as to be with difficulty discovered, it causes extreme pain after the expulsion of the urine; and it will not often be found to exceed a hazel-nut when first the surgeon is consulted. Hence lithotripsy will become even more employed, as it is made more generally known.

The advantages of lithotripsy cannot be sufficiently or truly estimated, without instituting a fair examination of the dangers respectively attending the two operations. I shall first review those that are incidental to lithotomy; and endeavour to determine how far the new operation enables us to avoid them, without presenting in their place others of an equally grave character.

No. 8.

There is no age at which lithotomy is impracticable. From the infant to the most aged, stones may be removed, by the lateral operation, with perfect ease and security. At the age which is peculiarly unfitted for lithotripsy the knife may be employed with comparatively little danger. It is difficult to mention any operation in surgery so uniformly successful as lithotomy is in children. The incomplete development, and the consequently little susceptibility of the parts involved—the small size of the vessels, and the little risk of hæmorrhage—the yielding nature of the textures, rendering force unnecessary in the extraction of the stone—are circumstances that combine to divest the operation of much of the danger that surrounds it, when performed on the adult. It is a rare occurrence to lose a young patient when the constitution of the child is favourable. The sister of one of the female wards told me that she had never lost a patient after lithotomy, and had had more than thirty do well. Much irritation in the system does not appear to be produced, even during the period of dentition, when surgical operations in general are accounted hazardous. I have cut a child for stone at the early age of sixteen months; and have assisted at an operation when the patient had only completed its thirteenth month. The removal of a source of irritation to the constitution may explain the little irritative effect that follows lithotomy in children. Though these young subjects are happily not liable to infiltration of urine into the cellular membrane, or to peritonitis, they are exposed to another source of danger, from sudden prostration, under which their powers will sometimes sink. This depression occurs in those children whose parents accustom them, even at their tender age, to the pernicious habit of dram-drinking; a custom partly arising from the erroneous idea, that gin, by increasing the urinary secretion, tends to allay the irritation produced by the stone. Such children, when brought into the hospital, being subjected to the lowering effects of a milder and restricted diet, and to the action of brisk purgative medicines, are rendered irritable and susceptible, and can ill bear an operation that exhausts their energy, and is attended with some loss of blood. A small dose of syrup of poppies, with a tea-spoonful of gin, or whatever liquor they may have been accustomed to, soon restores the tone of the nerves and the vigour of the

R

circulating system. After the operation is concluded, there is little suffering for the child to endure: the wound requiring no dressing, and no painful examination, the little patient proceeds, undisturbed, to complete convalescence. Another advantage which the child enjoys, is the absence of mental anticipation, a state of mind that perhaps constitutes half the sufferings felt at any operation, and may tend to increase the danger. The freedom from such anticipation in the child diminishes the actual danger, and also exempts its feelings from half the horrors which the man cannot but feel. Seeing, then, that so little risk and suffering attends lithotomy in children, it is difficult for us to find an equally safe and efficient substitute: it can scarcely, indeed, be said to be required.

From childhood to the age of puberty the dangers attending lithotomy can hardly be said to increase. Boys of thirteen years of age suffer scarcely more from the operation than children, and for the same reasons: but after puberty, the risk begins to be greater. The development which the parts about the neck of the bladder acquire increases the volume of the structures opposed to the knife: the incision is therefore necessarily larger; and thus the number of vessels divided is also increased. These vessels are not only of larger size than in the child, but they are relatively of larger calibre. The stimulus given to the circulation, and the additional and rapid growth of the organs at puberty, are attended by a corresponding enlargement of the pudic artery and its branches; which offers one, and perhaps the principal, source of danger which the operator has to encounter in the adult.

It is not ingenuous for lithotomists to deny the occurrence or the danger of hæmorrhage. It is unquestionably most formidable when it does occur; and I apprehend that few surgeons who have seen much of lithotomy have not occasionally witnessed a loss of blood larger than the patient could well bear, and which has had an indirect effect on the result of the operation. It is rare for patients to die immediately from loss of blood. The arteries are not large enough to afford a hæmorrhage sufficiently rapid to induce fatal syncope; but the draining sometimes continues for hours; either backward, into the bladder; or slowly, by the external wound; gradually exhausting the patient, and incapacitating him for the struggle which he may have

to undergo with visceral disease or inflammation. It is this secondary effect that constitutes the chief danger of bleeding after lithotomy, and usually takes place in patients who have slight enlargement of the heart and a large arterial system. The pulse is found to be full and large, even when the patient appears exhausted by the loss of blood: the lungs become gorged, and, under the depressed state of the nervous energy, become embarrassed in their circulation. The heart, thus encumbered by the difficult pulmonary circulation, relieves itself by serous effusion into the pericardium, and death speedily ensues. If inflammation come on, either in the peritoneum or the vesicle cellular tissue, the prostrated powers of the patient disable him from setting up a barrier to the mischief by a salutary adhesive process: in the latter case, the action assumes the suppurative form, and cellular abscess is the fatal consequence; and in the former, a slight extension of the peritonitis, producing opaque serous effusion, is sufficient to induce fatal prostration.

I may, perhaps, over estimate the ill effects of loss of blood, on the issue of surgical operations. It is from frequent observation of its effects in the larger operations that I have formed my opinion. I cannot understand the good which a free hæmorrhage is supposed by some to do, in the prevention of inflammation. Enough blood is lost at every operation, be the surgeon ever so careful, to unload a distended state of vessels, and to diminish the chance of excessive action. Beyond this, all that is lost tends but to increase the irritability of the patient, and to deprive nature of her powers. It is far better to lower the patient's system, should it be plethoric, by a well-regulated system of diet, not to the extent of inducing irritability, but to the point of preventing superabundant nutrition. It is very rarely that I bleed a patient before an operation, even when it is one that is attended with very little loss of blood. I prefer preparing him by diet; and defer taking blood from the arm, till symptoms of approaching inflammation demand it. There is a class of persons who are said to be benefited by taking away a pound of blood before the operation: these are, the hale and healthy men. These persons, it is true, are not rendered irritable, and appear none the worse for the loss; but such persons are not disposed to unhealthy inflammation, and the bleeding is alto-

gether unnecessary. I have notes of many cases of disease, of accident, and of operation, attended by a large loss of blood, which have been followed by inflammation, slight, but sufficient to destroy the already exhausted patient.

There are several sources that furnish the hæmorrhage; but, in all cases, the bleeding comes most freely from the upper angle of the wound. The higher therefore the incision is carried, the greater, *ceteris paribus*, is the probability of bleeding. The pudic trunk itself is, I apprehend, rarely wounded. The artery of the bulb, and the superficial perineal branch, often bleed profusely, especially the former. This vessel, traversing the upper angle of the incision, is generally divided; and its great variety in size, in different persons, and on the two sides of the same individual, renders the quantity of blood from this artery so variable. If the incision be carried very low down in the perineum, it may escape altogether; but it is not easy to cut below it. I have tried several times to perform the operation, on the dead subject, below the artery of the bulb; and though I could generally avoid it, by keeping the incision low, I believe it is almost always divided. The end of the vessel entering the bulb is often seen to bleed profusely, while its other extremity is closed; and pressure on the pudic artery does not restrain it. Indeed, hæmorrhage after lithotomy often continues, notwithstanding pressure may be made on the pudic trunk. I am averse to the practice, adopted by some surgeons, of plugging the wound with lint or sponge introduced on a catheter. The cellular membrane is irritated by it, and an unhealthy form of inflammation ensues; while the catheter, being soon blocked with coagulum, does not carry off the urine from the bladder. I have, however, found advantage in checking the bleeding by means of pressure, made upon the upper part of the left side of the perineum by a forked pad of lint fixed to a piece of cork. Pressure in this mode also reaches the deeper branches of the prostate, from which the blood sometimes oozes for a long time after the patient is placed in bed, and distends the bladder with masses of coagula. The accident of hæmorrhage is further increased by occasional varieties in the distribution of the branches of the pudic artery;—a remarkable instance of which was published by the late Mr. Shaw, and has been further illustrated in Mr. Stanley's work.

Infiltration of the cellular membrane with urine, as it escapes from the bladder, is another danger which the lithotomist has to dread. This, in some degree, is dependent on the manner in which the operation is performed, and partly on the constitution of the patient. It occurs more frequently in the adult than in the young subject. Most generally, it is the consequence of violence done to the deep perineal fascia, which sloughs or ulcerates, and allows the urine to escape backward, in the reticular tissue surrounding the neck of the bladder. I have, however, known the infiltration to ensue, when the stone being small, the incision to the prostate gland was limited, and no force was employed in the extraction of the calculus. In such cases, the constitution of the patient is in fault: an unhealthy form of inflammation attacks the cellular membrane and fascia, which breaks down and destroys the barrier that nature opposes to infiltration. The sloughing also extends to the superficial wound, and to the incision of the prostate; the inflammation induced by the incision partaking of the asthenic irritability, of the patient's system. A more frequent cause of infiltration is, the violence committed in dragging the stone through the incision in the gland.

The London Medical AND Surgical Journal.

Saturday, May 27th, 1837.

OPHTHALMIC HOSPITALS— QUACKERY.

None of the public charities of this community has exhibited, or continues to present, a more flagrant display of abuse and other misapplication of alms, than what are called OPHTHALMIC Hospitals. They have been daringly instituted to promote the private interests of selfish and unprincipled individuals;—they have contributed in no small degree

to obscure the atmosphere of ophthalmic surgery; and they have fearlessly given countenance to quackery and imposture.

The origin and principles which guided the conduct of those who gave birth to, and reared, the Eye Infirmary in Charterhouse-square, since imported to Moorfields, were some years ago ably exposed in a contemporary journal; and it appeared from the statement then given in the *Gazette*, that a new mode of operating for cataract had been discovered by the Surgeon of that Institution, which was trumpeted forth in the printed Reports, as being something far superior to all other modes of operating; but which for the private advantages of its author, the wily committee deemed it expedient to keep a profound secret; and even after the decease of its immortal inventor, with shame be it again told that this *secret* operation was continued to be performed at that institution, by certain individuals, to whom the *mystery* was imparted, but whose position, we hesitate not to say, ought to have placed them far above such conduct. The fraud thus committed on the public was, however, soon brought to light; and, as might have been anticipated, the *new* invention turned out to be an operation well known in Germany, and, one applicable only, to some particular cases of cataract.

The success which this institution met with, excited the jealousy of some individuals, whose practice was confined to the treatment of diseases of the eye; and hence another institution was soon established in Nassau-street, in the west end of the town, by the late Mr. Wathen Phipps, and although he had not the presumption, like the conjurors in Charterhouse-square, to claim the public confidence on the grounds of any new invention, he took the precaution of shutting the doors

of the institution against all such members of the profession as might feel disposed to observe the cases and the treatment which was employed for their cure. This Eye Infirmary was afterwards, for private ends, imported to Cork-street, where the back premises of the eminent oculist were devoted to his charitable purposes, and where they still remain a monument of its venerable founder.

The next remarkable era, in the history of our ophthalmic-bazaars, was the attempt of a celebrated pupil of the Charterhouse-square establishment, in strict imitation of the principles of his masters, to establish an Ophthalmic Hospital for the army; and many of our readers must recollect the exposé which was made before Parliament of the fraud and quackery of which the Surgeon of that Eye Infirmary was publicly accused. To crush this pseudo Military Eye Hospital, and to preserve the treatment of the blind within the legitimate and hallowed walls of the Army Medical Board, a counter-establishment was set on foot, by the able and no less charitable Director General, and an eminent individual was chosen, who was considered qualified in a most peculiar manner, to perform the important and no less anxious duties of the infant Military Establishment. A happy combination was next effected in this metropolis, by an able adventurer, who framed an institution by which those two invaluable organs, the eye and the ear, were both brought under the monocular observation and skilful manipulation of the able Director of this Adelphic institution.

It is impossible to review these multiplied ophthalmic *charities*, without contemplating the advantages which have resulted to the community and to medical science from these establishments. We are not aware that a single improvement

has been suggested, much less discovered, by any of the bright luminaries which have adorned the walls of Charterhouse-square and Moorfields from the commencement of the institution up to the present period. The improvements and discoveries in the Augean buikling of Cork-street being as yet quite unknown to the world, we have a right to infer will be equally valuable as those of Charterhouse-square. Time has also shown, that discoveries of the Military Depot have not been more effulgent; and unless it be admitted that cataract is curable by the direct application of the lapis infernalis, the Adelphic Institution of Dean-street, Soho-square, has no greater claim on the liberality, generosity, and support of a discerning and enlightened public.

It is, however, the events which have been lately taking place at the Westminster Ophthalmic Hospital, which are chiefly deserving of public animadversion at this time,—a system having been going on, to endeavour to establish the value of empirical remedies, by submitting unfortunate sufferers, who claim the assistance of the Institution, to a series of experiments for furthering the views and base purposes of empirics.

The experiments which were made on some of the unfortunate patients of this hospital, were fully exposed in this as well as in the other medical journals; and the same practice which has been lately adopted of selecting the sick poor for experimental researches, has brought to light, and will still further exhibit before the public, its manifold evils and the baneful effects which it exercises upon civilized society. It would indeed be well if some philanthropic individuals connected with our various public hospitals would step forward, and manfully oppose and discountenance all such practices of their medical officers, and contrive some

other means of remunerating the medical attendants, than the system which we alluded to in our last number, of extorting money from the student of medicine in the form of an attendance fee, or of giving themselves publicity and an ephemeral reputation by a sacrifice of the interests of the sick poor. The whole of our hospitals require to be speedily reformed, and until they are so, experiments will continue to be made on the patients to a greater or less extent in every one of those institutions. The whole hospital system is bad and must be improved, for we scarcely know a single institution to which the strictures which we have offered do not apply.

IRISH MEDICAL CHARITIES' BILL.

Lord Morpeth intends to introduce a bill for the regulation and support of public charities for the sick poor of Ireland, which is warmly supported by Mr. O'Connell and the liberal Irish members in the House of Commons. It will be opposed by the tory and monopolising Irish members who defend the Dublin College of Surgeons, whose members are at present exclusively privileged to be surgeons to county infirmaries. The college has sent a deputation consisting of Mr. Cusack Roney, Dr. Evanson, and Mr. Corr, to endeavour to palaver the government in favour of allowing the above shameful and unjust monopoly to continue. But the presence of Mr. Phelan and Dr. Nugent, the representatives of the great body of the profession in Ireland, sadly discomfits the monopolists, and we confidently predict, will completely destroy their sanguine hopes. It is to be recollected that the majority of the medical practitioners in the Sister Kingdom are members of the London and Scottish colleges, and that they were

compelled to leave their own country by the corrupt monopoly of the Dublin colleges, in order to obtain legal qualifications. They are ineligible to be county hospital surgeons, although most of them are medical officers of dispensaries, fever hospitals, and other public charities. No one but a monopolist will approve of the wholesale exclusion, or of the continuance of a law which is unjust upon the face of it. There is little doubt but the Commons will repeal it; but what will become of it in the Lords, is by no means easy to determine.

The time has arrived when all liberal-minded men agree, that duly qualified members of the profession in England, Ireland, and Scotland, ought to enjoy equal privileges in every part of the British dominions. This is the opinion of Mr. Warburton, who has at length announced his intention in the House of Commons last week, "that he will, at no distant period, introduce a bill for effecting important changes in the medical law, founded upon the testimony of persons, who were fully competent to form an opinion on the question." We hail this declaration with delight, as it affords the balm of consolation to the whole profession, except the monopolists. No law can render the polity of the profession so degraded as it is, and any modern enactment, more especial ly proposed by the astute and able chairman of the Medical Committee of the House of Commons, must be a boon to the profession at large, and a death blow to the monopolists.

FAMILY CORRESPONDENCE.

My dear Father,—There has been a regular *flare up*! at the Charing Cross Hospital, and the College of Surgeons has withdrawn what the Council call their RECOGNITION, which is nothing more than a power invested in that body by assily charter, to permit parties

connected with certain charitable institutions to extort money from the student under false pretences. I am quite ignorant of the cause of this proceeding, and Doctor Golding, (not Goolding as I last spelt his name,) takes the greatest care to keep us in blissful ignorance upon the subject. It does not require the eye of a lynx to observe that Golding is in a most nervous state of mind; one would really imagine that all the electricity of the "infernal machine," with which he used so successfully to astonish the minds and bodies of the unfortunate patients in Villiers Street, was concentrated in his own frame; when he was returning me the fee which I paid on entering, his very hairs stood on end, and every sovereign seemed to adhere to his pliable fingers with a bird-lime tenacity.

I have, however, my dear father, thank God, got my money back, so that your mind may be at ease upon this head. Howship never ventures near the place; I understand he has been guilty of some extraordinary transaction, and is afraid of being seen at the hospital until the very unfavourable impression it has created against him blows over, when it is expected he will have the audacity again to adorn its wards, as he and Golding are as thick as "FIVE IN A BED."

Doctor Shairman is constantly in the hospital; it is said he is "on the look out for squalls." This is highly probable, as he has the character of being a very sly old cock; and, without the assistance of glasses, generally picks up the corn, whilst the younger birds are amusing themselves in tossing about the chaff. I would not at all wonder if he was trying to get his nephew, who is a hedge preacher, a regular *Mauworm*, some good thing to satisfy his pious cravings. Doctor Cheerone looks terribly majestic, and tacks through the hospital wards like a "sea porpoise in a storm," or some other such production of nature's "handy work," in a similar predicament. I only knew a few days ago that Doctor Sigmond and Mr. Pettigrew had been officers in the hospital, and had left it in disgust; it is said they intend to lay before the profession and the public a full exposure of all the doings which have been going on there for some years; but as these jobbings, no matter how interesting they may be to the Council of the College of Surgeons, and to those interested in a more personal manner, can never put

"Bread on your table,
Or oats in your stable."

I shall not pester you further about them. I at all events have learned, during my short stay in London, the necessity of keeping my "bawbees," as you so funnily called them in your last, warm in my pocket, until I can be certain of getting value for them, and I shall not now enter to any hospital until I see the honourable member for Finsbury, were I even to lose the medical session by the delay. By-the-bye, I omitted to answer your query about Golding; he is the same person you allude to; but he never delivered any woman of more than two children at one lying-in. In the ridiculously extravagant case which appeared in the Sunday papers, the placenta was retained a few hours after the delivery, which gave rise to the report of the third child being extracted, and as the case occurred in some low vulgar neighbourhood, the *three black crows* were not long in being magnified into their proper proportions, and has to this hour remained uncontradicted.

You will, no doubt, be surprised to hear that I have cut the Greville Street Free Hospital School of Medicine. I fortunately only paid two pounds on account when I entered there, and my young Scotch friend with whom I am now living, advised me to do so. I have since made inquiries about the place, and learn that it was originally instituted by a Mr. Marsden, for the cure of malignant diseases, and that he and Mr. Jones, who was his assistant surgeon, encountering more difficulties in curing them than they anticipated, augmented their forces by getting Drs. Uwins and Ryan appointed as physicians to the hospital, Messrs. Tweedie and Lucas as surgeons to it. After a little time the newly appointed physicians and surgeons finding the malignant atmosphere of the place not to agree with their constitutions, retired from it in disgust. When I tell you that the Greville Street Free Hospital School of Medicine and all, would fit in the out-house at home, it is saying enough to you about it. The extraordinary puffing which is carried on in the newspapers and journals at the commencement of every session, would make one residing in the country almost imagine that one half of London consisted of Medical Schools, and that the other was a huge hospital, or some other such "imaginative extension of the mental powers," as Professor Mayo says in his invaluable physiological compositions. The advertisements thus put forward, contain

"promises" which never are realized; and to carry out the imposition at the end of each session, the most impudent paragraphs are put into the papers, particularly the country papers, giving the most flattering accounts of the number of pupils which thronged their empty benches, the great contest there was for prizes, &c.; that Mr. B. of Bath, Mr. D. of Durham, Mr. L. of Liverpool, Mr. N. of Newcastle, and so on to the end of the alphabet, obtained either a medal, a certificate of honour, or some other such CLAP TRAP; that the Hon. Mr. This, My Lord That, or the Bishop of some place presided at the "distribution of the prizes;" and though last, not least, that the self-styled professors were highly delighted to find their labours crowned with such wonderful success.

I can well conceive, after statements of this description appear in the papers, and are honestly read by a person in the country, that it might not be easy to convince him that the chairman on such occasions is totally ignorant of the real state of the school, and that having something in general more important to attend to he cares little about this, so long as it ministers to his vanity and his political speculations to blazon forth in the papers as having filled the chair. Nor are you in the country a bit the wiser of your son's or your pupil's progress by his getting a medal or a certificate, all such proceedings I now find are farces, a full account of which I shall lay before you in some of my future letters, as I have prolonged this to an unreasonable length.

My young friend Alexander Scott Macdonald, with whom I have been living since I received your last letter in which you approve of my joining him, is a very kind and sincere fellow, he attends at the King's College, and he gives me a very strange account of the number of pupils who are attending the medical classes. A report was in circulation a few days ago that the professors would suggest to the shareholders the propriety of closing its doors for a few years, and again opening them with something fresh, but I do not think this advice will be acted upon. I hear the shares which were originally £100. each can now be bought for £25., or even less; but I am not at all surprised at this, for the shares of the London University College are only of five pounds more value than those of King's College. Macdonald's habits are much more economical than mine, and al-

though, my dear father, I am satisfied from your considerate remittances you have every confidence in my prudence, yet as we of the Emerald Isle are too apt to calculate beyond our means, a curb like my friend Sandy Scott I look upon to be of the greatest advantage to me, particularly as he does every thing in a quiet, respectable, and steady way. Sandy's great grandfather, by the mother's side, was a distant relation of the Duke of Buccleugh, in consequence of which be sure when you speak of him in your letters to me not to forget always to call him **SCOTT MACDONNALD**, he is very particular about this; and though he is always upholding his great grand-father's dignity, yet he told a "good one" of him the other evening, he was very fond of the *Scotch toddy*, and the wags in Dalketh always called him Mr. Sott, leaving out the C.

Sandy Scott has brought a host of letters of introduction and intends delivering them next week. Write soon, my dear father, and believe me,

As ever, your affectionate son,

THOMAS.

P.S.—Dont send me Tuson's plates they are to be had here very cheap. You have made a mistake about Mayo—it is not the celebrated Mayo who has been dead this length of time, but Herbert Mayo, who was professor at King's College and whose place is supplied by the celebrated Doctor Todd, about whom Sandy Scott knows every thing, as hedoes about most people here.

THE ANATOMIST.

MUSCLES.

HEAD.

Occipito-frontalis. *Origin*, two external t irds of superior transverse ridge of occipital bone and posterior external part of mastoid process of temporal bone. *Insertion*, integuments of eyebrows, nasal bones and angular processes of the os frontis.

MUSCLES OF EXTERNAL EAR.

Superior Auris. *O.* cranial aponeurosis above external ear. *I.* upper and anterior part of cartilage of the ear.

Anterior Auris. *O.* posterior part of zygomatic process and cranial aponeurosis. *I.* anterior part of helix.

Posterior Auris. *O.* mastoid process. *I.* back part of concha.

FACE.

Orbicularis palpebrarum. *O.* internal angular process of os frontis and upper edge of tendo oculi. *I.* nasal process of superior maxillary bone and inferior edge of tendo oculi.

Tensor tarsi. *O.* posterior edge of os unguis. *I.* lachrymal ducts as far as puncta.

Corrugator supercilii. *O.* internal angular process of os frontis. *I.* middle of eyebrow.

Fyramidalis nasi. *O.* occipito—frontalis muscle, descends along nasal bones. *I.* compressor nasi muscle.

Compressor nasi. *O.* canine fossa in superior maxilla. *I.* dorsum of nose.

Levator labii superioris alaeque nasi. *O.* upper extremity of nasal process of superior maxilla, and from edge of orbit above infra-orbital hole. *I.* ala nasi, upper lip and orbicularis oris muscle.

Zygomaticus minor. *O.* upper part of the malar bone. *I.* upper lip, near commissure; sometimes wanting.

Zygomaticus major. *O.* lower part of malar bone, near zygomatic suture. *I.* angle of mouth.

Levator anguli oris. *O.* canine fossa above alveola of first molar tooth. *I.* commissure of lips and orbicularis oris.

Depressor labii superioris alaeque nasi. *O.* alveoli of canine and incisor teeth, of superior maxilla. *I.* integuments of upper lip and fibro-cartilage of septum and ala nasi.

Depressor anguli oris. *O.* external oblique line on lower jaw, extending from anterior edge of masseter to mental foramen. *I.* commissure of lips.

Depressor labii inferioris. *O.* side and front of lower maxilla, above its base. *I.* half of lower lip and orbicularis oris.

Levator labii inferioris. *O.* alveoli of incisor teeth of lower jaw. *I.* the integuments of the chin.

Orbicularis oris surrounds the mouth by two fleshy fasciculi.

Buccinator. *O.* two last alveoli of superior maxilla and external surface of posterior alveoli of lower maxilla, also inter-maxillary ligament. *I.* commissure of lips.

MUSCLES OF LOWER JAW.

Masseter consists of two portions: *Anterior portion.* *O.* superior maxilla where it joins malar bone, and inferior edge of latter. *I.* outer surface of angle of lower jaw.

Posterior portion. *O.* edge of malar

bone and zygomatic arch, as far as glenoid cavity. *I.* external side of angle and ramus of lower jaw.

Temporal. *O.* side of cranium, beneath semicircular ridge on parietal bone, temporal fossa, and aponeurosis. *I.* coronoid process of inferior maxilla to last molar tooth.

Pterygoideus internus. *O.* inner side of external pterygoid plate and pterygoid process of palate bone. *I.* inner side of angle of jaw and rough surface above.

Pterygoideus externus. *O.* outer side of external pterygoid plate, crest on great ala of sphenoid bone and from tuberosity of superior maxilla. *I.* into anterior and internal part of neck of lower jaw, inter-articular cartilage, and inferior synovial membrane.

MUSCLES ON ANTERIOR AND LATERAL PARTS OF NECK.

Platysma-myodes. *O.* cellular membrane covering upper and outer part of deltoid and great pectoral muscles. *I.* chin; fascia along side of lower jaw; and fascia covering parotid gland.

Sterno-cleido-mastoideus. *O.* upper and anterior part of first bone of sternum and sternal third, sometimes half, of clavicle. *I.* upper part of mastoid process and external third of superior transverse ridge of occipital bone.

Sterno-hyoideus. *O.* posterior surface of first bone of sternum, cartilage of first rib, sternal end of clavicle, and sternoclavicular capsu'e. *I.* lower border of body of os hyoides.

Sterno-thyroideus. *O.* posterior surface of first bone of sternum and cartilage of second rib. *I.* oblique line on ala of thyroid cartilage.

Omo-hyoideus. *O.* behind semilunar notch in scapula, from the ligament which passes over the notch, and from base of coracoid process. *I.* lower border of os hyoides, at the junction of its body and great cornu.

Digastric. *O.* groove, internal to mastoid process. *I.* rough depression on inner side of base of jaw, near its symphysis.

Mylo-hyoideus. *O.* mylo-hyoid ridge of inferior maxilla. *I.* base of os hyoides, chin, and middle tendinous line common to it and its fellow.

Genio-hyoideus. *O.* inner side of chin, above the digastricus. *I.* base of os hyoides.

Hyo-glossus. *O.* cornu and part of body of os hyoides. *I.* side of tongue.

Genio-hyo-glossus. *O.* eminence in-

side chin, below frænum linguæ. *I.* mesial line of tongue from apex to base, and body and lesser cornu of os hyoides.

Lingualis consists of fasciculi of fibres, running from base to apex of tongue, and lying between the genio-hyo-glossus, and the hyo and stylo glossi.

Stylo-hyoideus. *O.* outer side of styloid process, near its base. *I.* cornu and body of os hyoides.

Stylo-glossus. *O.* styloid process, near its tip and the stylo-maxillary ligament. *I.* side of tongue, as far as the tip.

Stylo-pharyngeus. *O.* back part of root of styloid process. *I.* side of pharynx, cornu of os hyoides, and thyroid cartilage.

MUSCLES OF THE PHARYNX.

Constrictor pharyngis inferior. *O.* side of cricoid cartilage, inferior cornu, and posterior part of ala of thyroid cartilage. *I.* with its fellow, along mesial line on back of pharynx.

Constrictor pharyngis medius. *O.* cornu and appendix of os hyoides, also stylo-hyoid and thyro-hyoid ligaments. *I.* mesial tendinous line, and cuneiform process of occipital bone.

Constrictor pharyngis superior. *O.* petrous portion of temporal bone, lower part of internal pterygoid plate and hamular process of sphenoid bone, also intermaxillary ligament, posterior third of mylo-hyoid ridge, and side of base of tongue. *I.* cuneiform process of occipital bone and mesial line of pharynx.

MUSCLES OF THE PALATE.

Levator palati. *O.* petrous portion of temporal bone in front of foramen caroticum. *I.* broad, into the velum.

Tensor, vel circumflexus palati. *O.* depression at root of internal pterygoid plate, spinous process of sphenoid bone and fore part of Eustachian tube; tendon turns round hamular process. *I.* into velum, meeting its fellow in the mesial line.

Motores uvulæ. *O.* posterior extremity of spine of palate bones. *I.* cellular tissue of uvula.

Palatoglossus. *O.* inferior surface of velum. *I.* side of tongue.

Palato-pharyngeus. *O.* inferior surface of palate. *I.* side and back of pharynx, and superior cornu of thyroid cartilage.

LARYNX.

Thyro-hyoideus. *O.* oblique ridge of

ala of thyroid cartilage. *I.* lower edge of cornu of os hyoideus.

Crico-thyroideus. *O.* fore part of cricoid cartilage. *I.* lower border of thyroid cartilage.

Thyro-arytenoideus. *O.* posterior surface of thyroid cartilage, near its angle. *I.* anterior edge of arytenoid cartilage.

Crico-arytenoideus lateralis. *O.* upper edge of side of cricoid cartilage. *I.* base of arytenoid cartilage.

Crico-arytenoideus posticus. *O.* depression on posterior surface of cricoid cartilage. *I.* outer side of base of arytenoid cartilage.

Arytenoideus fills the interval between arytenoid cartilages, and consists of two arrangements of fibres: *oblique*, run from apex of one cartilage to base of opposite one; *transverse*, are attached to posterior surface of each cartilage.

DEEP MUSCLES ON ANTERIOR AND LATERAL PARTS OF THE NECK.

Longus colli. *O.* bodies of three superior dorsal and four inferior cervical vertebræ, intervertebral ligaments, head of first rib, and anterior tubercles of transverse processes of the four inferior cervical vertebræ. *I.* fore part of first, second, and third cervical vertebræ.

Rectus capitis anticus major. *O.* anterior tubercles of transverse processes of four inferior cervical vertebræ. *I.* cuneiform process of occipital bone.

Rectus capitis anticus minor. *O.* transverse process of atlas. *I.* cuneiform process of occipital bone.

Rectus capitis lateralis. *O.* transverse process of atlas. *I.* jugular process of occipital bone.

Scalenus anticus. *O.* anterior tubercles of transverse processes of third, fourth, fifth, and sixth cervical vertebræ. *I.* upper surface of first rib, near its cartilage.

Scalenus medius. *O.* posterior tubercles of transverse processes of four or five inferior cervical vertebræ. *I.* upper edge of second rib.

Scalenus posticus. *O.* posterior tubercles of two or three inferior cervical vertebræ. *I.* upper edge of second rib between its tubercle and angle.

THORAX.

Pectoralis major. *O.* sternal half of clavicle, anterior surface of sternum, cartilages of third, fourth, fifth, and sixth ribs, and from aponeurosis common to it to external oblique muscle. *I.* by a flat band into anterior edge of bicipital

groove, and by an aponeurosis into fascia of forearm.

Pectoralis minor. *O.* external surfaces and upper edges of third, fourth, and fifth ribs, sometimes from second. *I.* inner and upper surface of coracoid process of scapula.

Subclavius. *O.* cartilage of first rib. *I.* external half of inferior surface of clavicle.

Serratus magnus. *O.* by eight or nine fleshy slips, from eight or nine superior ribs. *I.* base of scapula.

Intercostales are twenty-two in number on each side: eleven *internal* and eleven *external*.

External. *O.* inferior edge of each rib, commencing at transverse processes of vertebræ. *I.* external lip of superior edge of rib beneath, extending to behind costal extremities of cartilages.

Internal. *O.* at sternum from the inner lip of lower edge of each cartilage and rib as far as angle. *I.* inner lip of superior edge of cartilage and rib beneath.

Levatores costarum. *O.* extremity of each dorsal transverse process. *I.* upper edge of rib below, between tubercle and angle.

Triangularis sterni. *O.* posterior surface and edge of lower part of sternum and ensiform cartilage. *I.* cartilages of fourth, fifth, and sixth ribs.

MUSCLES OF THE BACK.

First Layer.

Trapezius. *O.* internal third of superior transverse ridge of occipital bone, ligamentum nuchæ, and spinous process of last cervical and all dorsal vertebræ. *I.* posterior border of external third of clavicle and acromion process, also superior edge of spine of scapula.

Latissimus dorsi. *O.* six inferior dorsal spines, and by lumbar fascia from all lumbar spines, from back of sacrum, posterior third of crest of ilium, and from three to four inferior ribs. *I.* posterior edge of bicipital groove of humerus.

Second Layer.

Rhomboides minor. *O.* lower part of ligamentum nuchæ and two last cervical spinous processes. *I.* base of scapula, opposite to and above its spine.

Rhomboides major. *O.* four or five superior dorsal spines. *I.* base of scapula from spine to inferior angle.

Levator anguli scapulae. *O.* posterior tubercles of transverse processes of four

or five superior cervical vertebræ. I. vertebral margin of scapula, between spine and superior angle.

Serratus posticus superior. O. ligamentum nuchæ, and two or three dorsal spines. I. second, third, and fourth ribs, external to angles.

Serratus posticus inferior. O. two last dorsal and two superior lumbar spines. I. lower edges of four inferior ribs anterior to angles.

Splenius colli. O. spines of third, fourth, fifth, and sixth dorsal vertebræ. I. transverse processes of three or four superior cervical vertebræ.

Splenius capitis. O. spines of two superior dorsal, and three inferior cervical vertebræ and ligamentum nuchæ. I. posterior part of mastoid process, and occipital bone, below its superior transverse ridge.

Third Layer.

Sacro-lumbalis. O. posterior third of crest of ilium, oblique and transverse processes of sacrum, sacro-iliac ligaments, and transverse and oblique processes of lumbar vertebræ. I. all the ribs, near their angles.

Longissimus dorsi. O. posterior surface of sacrum, and transverse and oblique processes of lumbar vertebræ. I. all dorsal vertebræ, and ribs between tubercles and angles.

Spinalis dorsi. O. two superior lumbar and three inferior dorsal spines. I. nine superior dorsal spines.

Musculi accessorii. O. superior edge of each rib. I. tendons of sacro-lumbalis.

Cervicalis descendens. O. from four or five superior ribs, between tubercles and angles. I. transverse processes of fourth, fifth, and sixth cervical vertebræ.

Transversalis colli. O. transverse processes of five or six superior dorsal vertebræ. I. transverse processes of three or four inferior cervical vertebræ.

Trachelo-mastoideus. O. transverse processes of three or four superior dorsal vertebræ, and as many inferior cervical. I. inner and back part of mastoid process.

Complexus. O. transverse and oblique processes of three or four inferior cervical and five or six superior dorsal vertebræ. I. into occipital bone, between its two transverse ridges.

Fourth Layer.

Spinalis colli. O. extremities of transverse processes of five or six superior

dorsal vertebræ. I. by four heads into spines of second, third, fourth, and fifth cervical vertebræ.

Semi-spinalis dorsi. O. by five or six tendons, from transverse processes of dorsal vertebræ, from fifth to eleventh. I. extremity of spines of two inferior cervical and three or four superior dorsal vertebræ.

Multifidus spinæ. O. first fasciculus arises from spine of vertebra dentata, and is inserted into transverse process of third, each successively in a similar manner down to the last, which arises from the spine of last lumbar vertebra, and is inserted into false transverse process of sacrum.

Interspinales—are situated between spinous processes of vertebræ.

Intertransversales—attached and situated as their name implies.

Rectus capitis posticus major. O. spinous process of second vertebra. I. inferior transverse ridge of os occipitis.

Rectus capitis posticus minor. O. posterior part of atlas. I. occipital bone, behind foramen magnum.

Obliquus capitis inferior. O. spinous process of second vertebra. I. extremity of transverse process of atlas.

Obliquus capitis superior. O. upper part of transverse process of atlas. I. occipital bone, between its transverse ridges, posterior to mastoid process.

UPPER EXTREMITY.

Shoulder Arm.

Deltoideus. O. lower edge of spine of scapula, anterior edge of acromion, and external third of clavicle. I. rough surface on outer side of humerus, near its centre.

Supra-spinatus. O. all scapula above the spine, which forms supra-spinous fossa, and from fascia covering muscle. I. upper and fore part of great tuberosity of humerus.

Infra-spinatus. O. inferior surface of spine and dorsum of scapula beneath, as low down as posterior ridge on inferior costa. I. middle of great tuberosity of humerus.

Teres minor. O. depression between the two ridges on inferior costa of scapula, from fascia covering it, and ligamentous septa. I. inferior depression on great tuberosity of humerus.

Subscapularis. O. all the surface and circumference of subscapular fossa. I. lesser tubercle of humerus.

Teres major. O. rough surface on in-

ferior angle of scapula, below infra spinatus. I. posterior edge of bicipital groove.

Coraco-brachialis. O. coracoid process and tendon of short head of biceps. I. internal side of humerus, about its middle, and by an aponeurosis, into ridge leading to internal condyle.

Biceps. O. short head, from coracoid process, long head, from upper edge of glenoid cavity. I. back part of tubercle of radius.

Brachialis anticus. O. centre of humerus by two slips on either side of insertion of deltoid, and fore part of humerus to its condyles. I. coronoid process of ulna and rough surface beneath.

Triceps extensor cubiti. O. long head, from lower part of neck of scapula and inferior costa. Second head, from ridge on humerus, below insertion of teres minor. Third head, from ridge below insertion of teres major, leading to the internal condyle, and from internal intermuscular ligament. I. olecranon process of ulna, and fascia of forearm.

Forearm and Hand.

Palmaris brevis. O. annular ligament and palmar fascia. I. integuments on inner side of palm.

Pronator radii teres. O. anterior part of internal condyle, fascia of forearm, intermuscular septa, and coronoid process of ulna. I. outer and back part of radius, about its centre.

Flexor carpi radialis. O. inner condyle and intermuscular septa. I. base of metacarpal bone of index finger.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

MAY 9,

DR. BRIGHT, President.

A short communication from Dr. Bosstock on the subject of the analysis of three specimens of urine, from a patient under the care of Mr. Earle, with rheumatism, who was treated with mercury. The author describes the first portion examined before the commencement of the mercurial course as the most aqueous he had ever seen, its solid contents being only 1.33 per cent., and the earthy salts being scarcely perceptible. After 13 days' use of mercury, the solid contents were increased to nearly 2 per cent., of which there was about the natural proportion of

the healthy phosphates. After a further interval of 11 days, the solid contents were increased to 4 per cent., and the phosphoric salts were greatly increased in quantity. In a specimen of the blood of the same patient, which the author received with the first specimen of urine, he found on analysis a quantity of urea.

REMARKS ON THE MALIGNANT DISEASES OF THE SKIN AND OF THE FACE. BY MR. CESAR HAWKINS.

The object of the author's communication is to describe a peculiar form of malignant disease of the face, which does not appear to him to have received any distinct notice by surgical writers, although its character is so well marked as to require a separate consideration. The term "malignant disease," however, having been employed in a very vague and ill-defined manner, the author commences by stating that he restricts the term *malignant* to such diseases as essentially possess a new structure, capable of exerting a poisonous influence in one or more of these several degrees—1st, upon the neighbouring textures, which are converted into a substance exactly similar, or at least analogous to that of the new formation; 2ndly, upon the absorbent system, so that the next glands become enlarged into a tumour, like that originally deposited, or 3dly, upon the whole constitution, so that the poisonous secretion of the newly formed part gains access to the circulating fluids, and tubercles of various forms, but of the same or analogous character, become developed in some distant organs or textures, which have no direct communication except through the blood with the parts in which the new structure was first formed. By this restriction of the term, the author excludes from among the malignant diseases of the face; 1st, the irritable and intractable ulcers, described by Mr. Earle in the 12th volume of the transactions of the society. 2ndly, the various forms of scrophulous lupus, which attack the nose, eyelids, and cheeks, and 3rdly, the several varieties of tubercular sebaceous disease, tubercular lupus, noli-me-tangere, &c., which occur in the same parts, and 4thly, hypertrophy of the nose, described by Mr. Hey, Civadier, and others. None of these contain any new structures to entitle them to be included in his definition. The author then proceeds to describe these distinct forms of malignant disease, which are illustrated by several drawings, casts, and

preparations, presented to the examination of members of the society. With the *common cancer of the face*, as it shows itself in the lower lip, most surgeons are familiar. When removed by the knife in its early stage, this disease does not return; if permitted, however, to advance until the contiguous glands become affected, the patient usually falls a victim to the irritation of the disease. In a few of these cases the poison is absorbed, contaminating the whole system, in which case tubercles are found in the liver and other viscera.

The second form of disease to which the author applies the name of *cancerous ulcer*, or phagedenic ulcer, occurs in the face of old persons, is usually stationary for a long time, until excited to ulceration by some accidental violence, and differs from the ulcer of ordinary cancer, by the skin around not being thickened and inflamed; by the almost entire absence of pain; by its slow progress, and other characters. This disease the author considers to be malignant only in the lowest degree, and advises its removal by the knife, or when the new substance is not very deep, by the chloride of zinc. To the 3rd form of the disease, the author employs the name of *cancerous tumour of fungous cancer of the face* of old persons, a disease which he believes to be hitherto undescribed. This disease presents the appearance at first of a small round tumour in the skin, generally in the cheek over the malar bone, or on the ala nasi. It is a little whiter than the surrounding cutis, being thinned by the growth of the tumour. It is easily distinguished from ordinary cancer by many characters of peculiarity, and is usually unattended with lancinating pain, previously to ulceration. When it forms upon the ala nasi, it is readily distinguished from hypertrophy of that part by the absence of surrounding redness and thickening, by its defined cyst-like limits, and by the absence of enlarged sebaceous follicles.

The author considers the disease to be intermediate in malignancy between the cancerous ulcer, and the common cancer, and that if sufficient care be taken to excise the whole, it may be removed with almost certainty of success.

The President asked, if in the symptoms any peculiarities arise from the mode of growth or the structure of the malignant tumours of the face.

Mr. Hawkins could not satisfy himself that any peculiarity existed in the pro-

gress of formation of these tumours, which he had termed schirrous and fungoid.

Mr. Perry wished to know from Mr. Hawkins, whether in cancer scroti, the liver, kidneys, or any internal viscera, were subject to contamination, and whether the enlargement of the inguinal glands was unfavourable towards an operation, for Mr. P. had seen cases where the operation was performed under those circumstances, when the enlargement disappeared soon afterwards.

Mr. Hawkins had not had an opportunity of examining many fatal cases of cancer scroti, and had not seen any morbid lesion in the internal organs; but he referred to a case of Mr. Langstaff, ably described in the transactions of the Society. Such cases were unusual. Mr. Hawkins would not regard the enlargement of the glands as a bar to the performance of the operation.

Mr. Macilwain wished to elicit from Mr. Hawkins some account of the constitutional symptoms which present themselves in those cancerous diseases. It happened to Mr. M., in the course of 16 years, to have six or seven tumours under his observation, which it was impossible to distinguish from carcinomatous formations. An operation in these cases was about to be performed, but during the delay occasioned by some accidental circumstance, they got quite well, and no one he observed would conclude these to be cancerous. He was once struck with a case of cancer of the lip in Bartholomew's Hospital, where an operation was also about to be performed, but owing to some slight delay, the case completely got well by the use of arsenic employed locally. In the treatment of these cases he has found more relief obtained by directing remedies to the constitutional symptoms than to any of the local ones; and the most common and, perhaps, constant general symptom in these cases, is an unusual excitability of the nervous system, not dependent on the disease, but existing prior to the symptoms of the disease in question.

REMARKS ON A PECULIAR SYMPTOM OCCURRING IN SOME CASES OF ENLARGED LIVER, BY I. G. MALCOLMSON, ESQ. SURGEON, MADRAS ESTABLISHMENT.

The object of the author of this paper is to describe a condition of disease in the liver, which he had observed to be productive of a peculiar sound as heard through the stethoscope. This sound was between a crepitous rattle and a

bleating, audible to the patient and even to the by-stander, and accompanied by a vibration of the parietes of the chest, communicated to the hand applied to the part. The author was at first unable to account for this symptom, but subsequent experience has enabled him to refer it to enlargement from abscess in the liver, or other abdominal tumour, compressing and forcing upwards a portion of the lung. In one instance the patient amused himself by producing, and removing by various changes of posture, what he (being a surgeon) had taken for intimation of approaching death. In a subsequent part of the paper, the author lays much stress on the danger of opening abscesses in the liver, before adhesion shall have taken place.

MEDICO-BOTANICAL SOCIETY.

May 10, 1837.—*Earl Stanhope, President.*

Twenty-Seven Years' Retention of Power by the Howary Poison.—This evening Mr. Iliff detailed some experiments which he had made with the howary poison, brought by Dr. Hancock from Guiana in 1810, and mentioned in the last report from this Society. The object of the experiments was not to determine by what mode poisons act on the system, but simply to ascertain whether the specimens of the howary arrows, prepared at least twenty-seven years since, still maintained their virtues. For this purpose, he dipped the tip of one of the arrows in warm water, and quickly withdrew it, and inserted it into the thigh of a rabbit; the effect was very slight; there were some twitches of the muscles, but the animal shortly after recovered. Another arrow, soaked for the space of two minutes, until the poison was fully moistened, was then inserted into the thigh of the same rabbit, and the animal became paralysed, and died in a few minutes. This experiment was repeated on another animal, in which it produced great quickness of respiration, convulsive twitches, and death, in the course of a few minutes. In this instance it was also found necessary to well moisten the point of the arrow. Some of the poison scraped off, and introduced by the mouth with the food, had not the slightest effect. In one instance in which the poison was inserted into the thigh, it retained its influence over the animal for some hours, but the rabbit eventually recovered. It

was, Mr. Iliff said, probable that, in this instance, the poison was not sufficiently applied. The two last facts were interesting, as showing the necessity of an abraded surface for the development of the action of the poison, and also the recovery of an animal, after remaining under its influence for several hours. The latter effect, he believed, had also been noticed by Dr. Addison, in his experiments with the howary poison. Mr. Iliff thought that the publication of the experiments which he had made might produce benefit, by preventing individuals from giving poisoned arrows away, however long they had been kept, without sufficient precaution.

LONDON MEDICAL SOCIETY.

May 15, 1837.—*Mr Bryant, President.*

ANEURISM OF THE ARCH OF THE AORTA.

SUDDEN DEATH FROM FUNCTIONAL DISEASE OF THE HEART.

Mr. Hooper exhibited a specimen of aneurism of the arch of the aorta, which had burst into the pericardium. He had been called to see the patient just as he had suddenly expired, and not having attended him before, he could only obtain the following history of his case:—He was forty-five years of age, and two months since had suffered from an attack of influenza, which left many of the symptoms of dyspepsia behind it, with occasional difficulty of breathing, and a rising in the throat, resembling the globus hystericus. For these symptoms he had been in the habit of consulting a physician, who considered the affection to be dyspepsia. On the day on which he died, he felt the difficulty of breathing coming on as he was walking out, and took soda-water for relief; as he was drinking the second bottle he fell down suddenly, and died immediately. On examination, an aneurism of the arch of the aorta, which had burst into the pericardium, was detected. The pericardium contained a clot of blood, weighing about a pound. The lungs, the liver, and the other viscera, were healthy.

Dr. Bennett related a case of sudden death from what he considered to be a functional disorder of the heart. The patient, a man, forty-one years of age, had generally enjoyed good health, but during the last five or six years had been subjected to great mental distress, and

for five or six months past had suffered from symptoms of dyspepsia, not of an urgent character, which did not lay him up, and only induced him to apply for medical advice occasionally. On Sunday he rose as well as usual, and ate a hearty dinner, at two o'clock; between four and five o'clock he was seized with great pain in the epigastrium, and a sense of constriction across the chest, with pain and contraction of both arms. He had suffered from pain in the left arm before. He took brandy and water, but gradually got worse. At seven o'clock a medical man was sent for, and on his arrival in a very short time afterwards, he found that the patient had been dead, apparently, for twenty minutes. On examination, the body, externally, was muscular; the neck and face were livid. The chest was remarkably large and well formed; lungs not collapsed, but gorged with blood in every part. There were some old adhesions of the pleuræ. *Pericardium* healthy; *heart* flattened, flabby, and somewhat enlarged; a quantity of fatty matter was at its base. Its cavities displayed nothing particular, but there was a slight hypertrophy and dilatation generally. Coronary arteries healthy. *Stomach* distended with partially-digested food. Intestines and brain healthy. He (Dr. B.) believed that the heart was subject to variety of functional diseases, which might cause death, without the presence of any apparent lesion.

Dr. Whiting inquired whether the patient might not have been suddenly attacked with severe peripneumonia? He thought this more probable than that the heart was in fault in the present instance.

Dr. Bennett said, that there were no symptoms which could be attributed to peripneumony. Such general engorgement of the lungs was against the presumption of the presence of peripneumony; the sudden functional disease of the heart would, however, account for this symptom.

EPILEPSY, AND FUNCTIONAL NERVOUS DERANGEMENTS.

Dr. Uwins being now called on for his announced paper on this subject, stated that he should have had more reluctance in breaking into the course of discussion which the narration of Dr. Bennett's case might lead to, did he not feel that the few remarks which he had just put together, and now held in his hand, had an especial bearing upon the same principle

as that which Dr. B. advocated, namely, that a vast deal of morbid condition often existed without any cognizable change in structure. Functional disorders, (the Doctor went on to say, in his paper,) were the disorders to which he was desirous of directing the attention of the Society at this time, because it was of such maladies as epilepsy, and all its numerous alliances, that we might rightly predicate that they had neither "local habitation" nor "name." He objected, *in toto*, to the very principle itself of classification and nomenclature, and hailed the approach of that æra in medicine when it should be studied and cultivated, as now are the collateral sciences of anatomy, physiology, and surgery. He had recently, he said, been hearing some masterly lectures on the spinal and cranial brain, and so different were they from the cutting and slicing and piecemeal demonstrations which were wont to be exhibited, that he could not avoid, for the time, wishing that the period of his own youth and pupillage had been postponed to the present day. "It is," Dr. U. went on to say, "because medicine still retains the barbarisms and crampings of these scholastic methods of designation and definition, that it has not made the same progress as physiology and surgery. But it will not long be thus obstructed. The wheel-drags are fast being loosened, nosology is vanishing into the nothingness out of which it originated, and the theory and practice of our art are about to assume a novel and commanding aspect." He then attacked the principles which referred all functional lesion to vascular change as its *primum mobile*. "Inflammation!" he exclaimed, "where is the inflammation in that inmate of a madhouse, who is raving to a terrific excess? Where, in that melancholic, who, in the corner of his apartment, is muttering to himself in the most incoherent manner; or in that epileptic who lies on the floor exhibiting direful contortions and convulsions? What evidences of inflammation do we find in the stertorous and insensible apoplectic, in the laughing, weeping, singing, and bawling of hysteria? No, all these affections are but manifestations of irregularity in cerebral energy,—of this faculty and function being in a condition of morbid activity, while others are as morbidly passive, or quiet." He had no wish at the present moment "to touch upon the brink of all that was hateful" in the minds of many of his respected compeers; but

he felt assured that to homœopathy and to phrenology would the practice and theory of our art henceforth find itself most indebted. He did not mean to deny that many discoveries had been made by experiments on animals; he admitted that to Le Gallois were we beholden for having discovered many functional peculiarities about the regions of the cerebellum and medulla oblongata; that to Wilson Philip were we obliged for his manifestation of the faculties resident in the eighth pair of nerves; to Charles Bell and Mayo for demonstrating the absolute origin of the nerves of motion, as different from those of feeling; to Magendie for some insight into the distinctive functions of the fifth pair; but to those physiologists and pathologists were we still more indebted who, at vast pains and labour, had, by observation alone, detected the laws of life, and discovered the elements of morbid being.

Having thus traced out the errors of the old pathologists, the Doctor made especial reference to epilepsy as appearing to have considerable connexion with those parts where the cranial and the spinal brain make their junction. He alluded to the doctrine of Boerrhawe as being substantially correct, and referred to two experiments, the one by the late Dr. Fothergill, of electricity having both suspended and immediately afterwards restored an animal to life; and the other by Mr. Sewell, related in Mr. Mayo's "Pathology," in which a horse having a locked-jaw was killed by poison—or, at least, both life and the disease were suspended,—and restored to animation by inflation of his lungs; in which last experiment, as well as in the first, Dr. Uwins seemed to suppose that electric energies were brought into play. The paper was concluded by several corollaries, which mainly bore upon what the author seemed to have principally in view during the whole of the reading,—viz., that a due and especial regard in all our reasonings should be paid to the laws of organism; that then symptoms should be registered, nosology banished, and practice (directed by the teachings of disturbed organism) established on its ruins.

Dr. Shearman considered that two of the assertions made by Dr. Uwins had not yet been proved, namely, that to various portions of the brain various functions should be allotted, or that nosology was established on nonentities, for it gave name to an assemblage of symptoms which were evidences of the disease.

For instance, who ever saw jaundice without the *cutis flava*, and that was one of the symptoms on which the name was founded?

Mr. Jones was fully of opinion that many cases occurred in which the symptoms preceding death were not indicated by examination afterwards. He thought, however, that the opinion that all diseases were of this character, was erroneous.

Mr. Kingdon agreed with Dr. Uwins, that nosology was badly founded. Indeed, after twenty-five years' practice, he had never seen an assemblage of symptoms which bore out the name of the disease. When a student in the hospital, he had never been able to get a physician or surgeon in those institutions, when pressed hard, to give a name to a disease.

The debate was here adjourned.

HOW TO STOP BLEEDING.

The *Revue Medicale* states, that when all other means fail in arresting hæmorrhage, a little oil of tobacco has immediately succeeded. That which collects in the stems of pipes which have been long smoked will answer perfectly. The discovery was made by Humel, a chemist, at Berlin, and his mixture is eight ounces of distilled water, two drams of oil of tobacco, and a few drops of ethereal animal oil. This has been found so effectual, that, by a recent decree of the Minister of the interior at Munich, all apothecaries are ordered to keep it prepared.

PRESERVATION OF ANIMAL SUBSTANCES.

M. Gannal, of Paris, has discovered, that a solution of the acetate of alumina injected into the arteries of a dead body will preserve it for a long time. This is also applicable to the preparation of specimens of natural history. It will enable the anatomist to pursue his labours with comfort at all seasons of the air, and even without the aid of the chlorides of lime or soda.

CHLORIDE OF ZINC AS A REMEDY FOR NÆVUS MATERNUS.

Mr. Calloway, of Guy's Hospital, has lately applied chloride of zinc, like a piece of caustic, to nœvus maternus, at repeated intervals, until the skin became slightly discoloured. It has been attended with considerable success. It has also appeared useful in some cases of lupus.

NOTES OF LECTURES ON PHYSIOLOGY.

By DR. FLETCHER.

*Delivered in the Argyle Square School of
Medicine, Edinburgh.*

No. XXV.

ETIOLOGY.

Predisposing Causes of Disease—Habit of Body—Typhus and Synocha—Four Different Kinds of Plethora—Apoplexy—Diseases of Summer and Winter—Individual and National Constitutions—The Plague, Yellow Fever, and Sudor Anglicanus—Climate and Diet—Diseases of Hot and Cold Countries—Diseases of the Skin, Liver, Lungs, and Kidneys—Diseases of the Rich and of the Poor—Exciting Causes—Ancient and Modern Opinions—Balance of the Fluids—Humoral Pathology of Phlegmon, Erysipelas, Scirrhus, and Dropsy—Bad Humours and Ill Tempers—Pathology of the Arabians—Vitiation of the Fluids—Hoffman and Cullen—Fluidists and Solidists—Peccant Humours—Explanation of Dr. Brown's System—Direct and Indirect Debility—Sthenic and Asthenic Diseases—Errors of his System—His Good Pathology and Bad Practice—Changes of the Blood in Different Diseases—Cause of the Buffy Coat—Sir Everard Home, on Colourless Globules, with coloured Envelopes—Holland on the Blood in Inflammation—Parr on Scrofula—Blood in Scurvy, Diabetes, Gout, Phthisis, and the Exanthemata—Acid and Alkaline Blood—Albuminous Blood—Diseases not propagated by the Blood—Home's Experiments on Inoculation—Hydrogen and Carbon in the Blood—Spontaneous Combustion—Cyanosis, Cynanche Trachealis, Rachitis, and Exostosis—Heat and Cold—Analogous Effects of a Hot Iron and Frozen

No. 9.

Mercury—Air—Pressure of the Atmosphere—Influence of its Changes on Diseases—Range of the Barometer—Medical Use of the Diving Bell—Mode of killing Whales—Pain in the Tympanum, in Rarefied Air—Moisture in the Air—Effect of Odours and Putrid Effluvia—Deleterious Gases—Smoke and Dust—Contagion and Infection—Difference between them—Marsh Miasmata—Mode in which they act on the System—Sir Astley Cooper's Experiment—Latent Stage of Diseases—Aliment—Poisons—Acrid Poisons—Corrosive Poisons—Narcotic Poisons—Habitual Use of Poisons—Poison-proof Persons—Narcotic Acrid Poisons—Indian and American Poisons—Astringent Poisons—Poisoning with Lead—Septic Poisons—Difference between a Venum and a Virus—Venom of the Rattle Snake—Virus of Hydrophobia—Venomous Reptiles—Poisonous Fishes.

4. Habit of Body.—It is not climate and diet that are the predisposing causes of disease, though they are often said to be so, but the habit of body induced by them. The equilibrium of the functions is only maintained in temperate climates. People are more subject to typhus in hot countries, and synocha in cold, from the greater plethora which exists in the latter. This plethora may be divided into four species:—1. Plethora vera. 2. Plethora ad molem, where the blood swells within its vessels. 3. Plethora ad spatium, where the vessels contract on the blood. 4. Plethora ad vires, where the propelling strength is lessened. In winter, we are more liable to apoplexy, owing to the alternations of temperature to which we are then subject; and, in consequence of which, the plethora ad molem and the plethora ad spatium, are constantly encountering each other. In summer, we are liable to the plethora ad molem only; for we cannot make ourselves cold then, though we can make

ourselves warm in winter. Apoplexy, therefore, is less frequent in summer.

There is such a thing as a national, as well as an individual constitution. It generally displays itself in exempting natives from those diseases to which foreigners arriving in the country are liable. Thus, it protects the Turks at Constantinople from the plague, and the natives of the West Indies from the yellow fever. But, sometimes, this constitution predisposes to disease, as in the case of the sudor Anglicanus, which spared all foreigners in England, and attacked Englishmen abroad. It was the same with the plague at Copenhagen, and with fever at Basle, in Switzerland.

Climate and diet have great influence in producing that habit of body which predisposes to disease. In hot countries the skin and the liver are more liable to disease, and the lungs and the kidneys in cold; because those parts have respectively more to do in a hot and in a cold climate. The liver is vicarious of the lungs, and the skin of the kidneys.

With respect to diet, excess in any particular kind of food predisposes to certain diseases, through the medium of the habit of body which it induces. The rich are less prone to contract diseases, but are more liable to sink under them.

II. *Exciting Causes.*—These consist principally of peculiarities in the stimuli to irritability, which, as we saw when treating on that subject, are either direct or indirect. The principal of them are heat, air, aliment, sympathy, and the passions. We shall treat of them in order, after giving a sketch of the ancient and modern systems of medicine, as founded on the supposed action of these exciting causes.

Health was anciently thought to consist in a *κρᾶσις*, or balance of the four fluids of the body;—blood, yellow bile, black bile, and phlegm. A loss of this balance, (called *ἀκρᾶσις*, or *intemperies*,) was of course thought to constitute disease. A phlegmon was attributed to a preponderance of blood; erysipelas, to that of yellow bile; scirrhus, to black bile; and dropsy to phlegm. This was the first humoral pathology, but was not founded on vitiation of the fluids. We still speak of “a bad humour,” or “an ill temper.”

Themison was one of the mechanists who attributed all diseases to stricture and laxum. The Arabians introduced vitiation of the blood. This was another humoral pathology. It continued even

to the time of Cullen, and is still prevalent among the vulgar. Hoffman propagated the doctrine, that disease depended not on vitiation of the fluids, but on a disturbance of the molecular actions of the solids. Before him it was thought that the vis medicatrix nature (by whatever name it was known) sent out an army to repel the invasion of some “peccant humour” which had intruded into the system. If they caught the enemy, they boiled him (“coction of the humours,”) and thus obliged him to depart in an abscess (*abcedo*). If, on the other hand, the enemy prevailed, gangrene was the result.

Brown said that all diseases depended on a loss of balance between the irritability of the system, and the stimuli to that irritability. According to him, debility existed in every case; but was either direct or indirect. Indirect debility he attributed to increased stimuli, and the disease was then called sthenic. Direct debility was from accumulated excitability; and the disease was then asthenic. On these principles he explained the fact, that a hot iron and frozen mercury will produce the same effect. He was wrong in saying that a certain stock of irritability was given to every man at birth, instead of its being continually renewed; and that this irritability was the same in all parts of the body; whereas it is different in every organ. He was also wrong in allowing his views of asthenic diseases (fever, for instance) to make him give stimuli, and forbid bleeding. He regarded the blood as a stimulus only; whereas it is also a load. He stimulated in all cases. He always whipped the horse; and we do so sometimes, as in ophthalmia; but we generally lighten the load also. He was probably the best pathologist and the worst practitioner that ever lived.

The blood is said to be vitiated in inflammation, scrofula, diabetes, the exanthemata, scurvy, gout, putrid diseases, &c. The blood is changed in these diseases, but probably only as an effect; for all exciting causes are supposed to act primarily on the nervous system.

In inflammation, the coagulum of the blood is finer than in health, and is buffed and cupped. The tunica coriacea, or buffy coat, has been said to be owing to the descent of the red globules of the blood, from its coagulating more slowly than in health. But if this were the case, the line of demarkation between the buffy coat and the other part of the co-

agulum would not be so well marked as it is. Again, if we draw a streak on paper with the blood, the buffy coat will be at the sides, and not on the surface. Beside, the coagulation of the blood is not slower, but quicker, in inflammation. The buffy coat may, perhaps, be owing to the quicker and firmer coagulation, which presses out the red particles; and thus quicker and firmer coagulation is owing to molecular changes. It was once thought to be from something mixed with the blood, and to be not the effect, but the cause, of the disease. Bleeding was therefore ordered again and again, to get rid of it. It consists, as Sir Everard Home says, of globules of lymph, divested of their colouring envelope; and which swim from their less specific gravity. Holland says there is more oxygen in the blood in inflammation, owing to the expirations predominating over the inspirations.

In scrofula, according to Parr, the blood is too albuminous; and, according to others, too acid and stimulating. Hence soda was given. In scurvy it was thought to be too alkaline; and hence acids were given: but a cabbage will cure scurvy as well as acids.

In diabetes there is said to be too little nitrogen in the blood, so that it does not form urea in the kidneys, but sugar. There is no sugar in diabetic blood, though it was once thought there was. In gout there is thought to be too much nitrogen, and lithic acid abounds.

There is no proof of vitiation of the blood in exanthematous diseases; for we cannot communicate them by inoculation with the blood. Home endeavoured to prove that they could be so communicated. He scarified the arm of a person affected with measles; dipped cotton in the blood, and applied it to the nostrils of another person. The latter took the disease; but no doubt some of the secretion from the skin was also taken up by the cotton, and the person inhaled the miasm.

Phthisis has been referred to excess of oxygen in the blood; and gout to a deficiency. Spontaneous combustion has been attributed to an excess of hydrogen; and cyanosis to an excess of carbon. There has been said to be too much fibrin in cynanche trachealis, because a fibrous membrane lines the trachea; too much acid in rachitis; and too little in exostosis. This doctrine is dying a natural death.

We now come to a consideration,

in detail, of the exciting causes of disease.

1. *Caloric, and its abstraction.*—Cold can never cause a primary contraction of the blood vessels. It first produces a collapse, to which excitement and contraction succeed; but if the cold be very great, life may not be supported till reaction occurs.

2 *Air.*—A change in the density of the surrounding air, is said to cause hæmorrhage and asthma. The range of the barometer (three inches) makes a difference in the pressure of the atmosphere on a man's body, of four thousand pounds out of forty thousand. Carson suggested a descent in a diving bell, as a cure for phthisis; but the patient he sent down, was killed by hæmorrhage on coming up, the manner in which whales are killed, illustrates the influence of a difference in density of the surrounding medium. When struck, they dive to great depths; and on coming up, blood spouts profusely from every wound. If a great and sudden change take place in the density of the surrounding air, great pain is felt in the tympanum, from the expansion or compression of the air contained in it; which causes severe pressure either from within or from without, on the membrana tympani. This is experienced in ascending a high mountain or rising in a balloon; and from an opposite state of the surrounding air, in going down in a diving bell. Changes in the moisture of the air do not affect diseases *per se*; but they do from the difference of temperature which they occasion. Atmospheric air generally contains five grains of water in a cubic foot. Moist air is favourable in phthisis because less stimulating.

Odoriferous particles in the air can only cause syncope. Putrid effluvia are not deleterious, unless by exciting disgust; in which case they act through the medium of the passions. Contagious miasmata are positively deleterious; putrid effluvia (as proved by Chisholm and Bancroft) only indirectly so.

Deleterious gases may cause asphyxia, either by closing the glottis (as all stimulating gases do), or by entering the lungs; where they are inert, but exclude respirable air. The latter comprehend oxygen, hydrogen, nitrogen, the protoxide of nitrogen, and carbonic oxide; all the others belong to the first class. Recoveries are more frequent after exposure to the first class, than after inhaling the second; and therefore carbonic acid is less fatal than carbonic oxide.

Smoke and Dust are said to produce asthma, bronchial calculi, or phthisis, and ophthalmia. Those are liable to such diseases who work in dusty places; as dry-grinders, needle-makers, chimney-sweepers, and flax-carders.

With respect to contagion and infection, the first (according to Baillie) comprehends the diseases which are communicable from one person to another; while the latter affects several persons together; infection is the consequence of the general state of the air, and not of communication from one person to another. An epidemic may belong either to one class or to the other. Typhus fever seems to belong to both. Scarlet fever, measles, small-pox, syphilis, hydrophobia, &c., are contagious, from vitiated secretions. Intermittent fever arises from infection.

Contagious miasmata have no sensible properties. Fontanelle and Mescati analyzed marsh miasmata, and the contagious effluvia of the plague and fever; and found their composition the same as that of pure air. They have been said to contain various gases, hydrogen being the chief ingredient; but we can form all the combinations of hydrogen, and yet we cannot produce miasms. The latter are derived from vitiated secretions of animals and vegetables, and cannot be imitated in the laboratory. The decomposition of organized matter never produces them: they come not from dead but from diseased and dying animals and vegetables. Hence it is more dangerous to open a body recently dead, than after a longer period; because the secretions are not yet decomposed. The poison of the viper has the same composition as gum arabic,—the most bland substance in nature; and therefore we are not to be surprised if we detect nothing peculiar in the analysis of miasmata.

With regard to the absorption of these miasmata, the lungs, the stomach, and the skin, are said to be the avenues by which it takes place. The lungs are the most likely, their surface being greater than that of the stomach or skin; the access of air to them more frequent; and the absorption from them more rapid. Sir Astley Cooper inclosed all his body except the head, in vapour of turpentine, and found that his secretions were not affected; but a single whiff of air loaded with this vapour, taken into the lungs, made the secretions smell of turpentine. It is questionable whether such vapours

and miasmata may not act without being absorbed at all; by causing a primary irritation, which is propagated by sympathy. No doubt many substances are absorbed; but it is doubtful whether this is necessary. When a mother communicates variola to the foetus, it is thought to be through the medium of her vitiated blood; but in another case the foetus may become affected with variola while the mother remains free from it. Here it must be through the medium of miasmata, and probably is so in the former case.

Marsh miasms increase the liability of those who suffer from, to imbibe the same diseases afterward; but all other infectious matters lessen the subsequent liability. If this were not the case, a patient would hardly recover in a fever hospital. But his disease has lessened his susceptibility to the surrounding contagion. This is probably from exhaustion of irritability. In the same way, in the case of those diseases which affect a person only once in the course of his life, this subsequent immunity appears to be from the loss of irritability of certain tissues. He may be liable to other diseases, in the same way as a person who has a diminished irritability of the nose for snuff, is as sensible as ever to ammonia, and various odours. The specific irritability is lessened, but the general irritability remains unimpaired.

The latent stage of contagious diseases is that period of the excitement of the blood vessels which precedes their collapse. Its length varies in different diseases, and in different instances of the same disease. Some contagions act at once; others, after several days. Small-pox, by inoculation, takes effect in seven days; but if taken naturally, it requires fourteen. It is less violent in the former case, owing to the collapse being less after the shorter excitement. The sooner catarrh comes on after exposure to its cause, the slighter it will be, and the sooner over. A pinch of a sarum applied to the nostrils produces a long excitement, during which it appears to have no effect; but the collapse which succeeds is proportionately violent. A blistering plaster acts the moment it is applied to the skin; but we do not feel it till the collapse of the vessels takes place, for then the blood presses on the nerves.

3. *Aliment*.—Excess of food leads to apoplexy, gout, angina pectoris, asthma, polysania, calculi, and inflammations of various kinds. Deficiency of food ex-

poses to diabetes, dropsy, and all the diseases arising from debility.

Poisons may be divided into six classes:—1. *Acrid*. 2. *Corrosive*. 3. *Narcotic*. 4. *Narcotico-acrid*. 5. *Astringent*. 6. *Septic*. They produce catarrh, cholera, jaundice, apoplexy, palsy, tetanus, and various other diseases, as we shall see more particularly when we come to enumerate them in detail.

1. *Acrid*.—This class includes oxalic acid, elaterium, colocyinth, and all strong purgatives. They act vitally, producing inflammation.

2. *Corrosive*.—These act chemically, destroying the part to which they are applied. They comprehend all mineral acids, alkalies, and salts, except those of lead.

3. *Narcotic*.—These produce stupor; as opium, hydrocyanic acid, &c. In former times, only narcotic poisons were known; and it is only in those times that we meet with stories of persons who could not be poisoned. No doubt, however, the habitual use of poisons lessens the susceptibility of the system to their influence.

4. *Narcotico-acrid*.—They produce inflammation as well as stupor. This class comprises belladonna, hyoscinianus, conium, tobacco, and all the poisons which produce tetanus; such as urari, bruca, arsenic, secale cornutum, strychnia, arnica, rhus tox-icodendron, upas artiar, ignatia amara, menispermum cocculus, &c.

5. *Astringent*.—The salts of lead furnish the only examples of this class. They act by constricting the muscular fibres.

6. *Septic*.—To this class belong sulphurated hydrogen, poisonous fish, and all venoms and viruses. The difference between a venom and a virus is, that the former is a natural secretion designed for the use or protection of the animal, like the poison of the rattle-snake, or the wasp; whereas the latter is a morbid secretion, the consequence of disease, or the poison of hydrophobia. The principal venomous animals are the coluber berus (viper), the apis mellifera (bee), the nespa (wasp), the guat, and the scorpion. Orfila mentions the boa constrictor; but it probably kills only by constriction. The principal poisonous fish are the mybilus marinus, or muscle; the balistes, or old wife; the coryphæna, the perca major, the scomba maximus, the yellow-billed sprat, and other West Indian fish. The diseases which these septic animals produce are urticaria, catarrh, jaundice,

cholera, and at last palsy, and nervous apoplexy. When fatal, it is generally through the medium of the last. Sulphuretted hydrogen is not poisonous, unless introduced into the blood. When it does harm, therefore, in any other way, it is through the medium of the passions, from the disgust which it excites owing to its disagreeable odour, and its being the result of putrefaction.

LECTURES ON SURGERY,

BY

JOHN HUNTER, F.R.S.

ORGANIZATION AND ACTION.

General Views of Organization and Action—Arrangement of matter into certain Forms to answer the End required—Formation of Organs—Organs arranged according to certain Laws constitute Animals—Organization and Life distinct from each other Mr. Hunter's own Case—Of the second, Digestion, circulation, and Respiration are most closely connected with the first—Others, as Motion of the Limbs, more distantly—Motion may be caused by elastic Forces, reacting as in Ligaments—Nutrition and Absorption—Arteries, Veins, and Absorbents.

From what I have already said, it must appear that original or common matter has been first so decomposed, and then again so combined, as to become animal matter. This animal matter next became so arranged as to become alive. Now I shall observe that these combinations and arrangements are differently modified, so as to produce the various kinds of animal substances; some of which have their parts so disposed as to have motion among themselves, as muscles; others to have sensation, as brain and nerves; and in others the living parts are so disposed as to acquire other properties, as elasticity, rigidity, &c.

Solidity, in a certain degree, is necessary for self-motion; for parts cannot produce motion in one another without some resistance or fixed point of motion. We therefore find the acting parts of an animal composed of solids, or the parts which compose them could not coalesce together by the attraction of cohesion; and it is necessary that it should be so, as

without this no determined action could be produced.

Now we have gone so far with the materials of an animal, let us next examine how these materials are disposed so as to form an animal. These materials may now be considered in a mechanical point of view, like the component parts of a machine, each of which has its destined use and own peculiarity of form. These are united with each other to form parts, the whole forming organs of various kinds to produce the mechanical effects required. These organs, again, united according to certain established rules, form animals. This compounding of animal matter is what should be understood by organization.

Now if this idea of organization is just, organization and life are two different things; for, according to this definition, a dead body is as much organized as a living one, for in the dead body the same mechanism exists as in the living one.

Organization, then, comes nearest our ideas of the mechanical formation of parts, and the ultimate effect must be mechanical; for it is impossible to produce motion in matter without having a mechanical effect.

Having considered simple life, and the general idea of what is called organization, I shall next consider *the Actions of an Animal*.

I have said that animal matter is so constructed as to be endued with a power of self-motion, as in a muscle; and as we can hardly conceive any part of an animal entirely passive or free from motion, since all parts grow and are nourished, we must suppose this muscular structure very universal in an animal body, though this power has been considered principally in regard to muscles, properly so called, whose actions are plainly visible to the eye.

The different circumstances necessary for the composition of a muscular fibre, with the mode of action of a muscle, I shall not touch upon, the field being too large for my present purpose. I shall only observe that they are the animal powers by the immediate actions of which every, even the smallest part, of an animal is moved.

Every machine has its power; a clock has either a spring or weight, and so on. In mechanics the parts are dependent on one another, so that some *one* power is necessary to put the whole in motion; in mechanics too there is commonly but one ultimate effect produced,

whereas in an animal body there are a thousand. The powers therefore of an animal body are differently placed and circumstanced from what they are in an inanimate machine: it is not one power that is setting the whole to work, because if that were the case an animal's actions would always be the same, but he is at rest in one part, moving in another, and so on; and as this is the case, he must have power in every part, so that his powers are diffused through the whole animal, which is almost composed of powers.

The actions of an animal, considered as a whole, should be divided into two kinds. 1st. Those actions common to every part alike, such as those which are employed in the internal operations of the machine, as growth, alteration, building up, taking down, &c., every individual part (the smallest conceivable) acting for itself only, which actions may be called immediate. These are probably performed by the ends of vessels, whether the terminations of arteries or the beginning of absorbents; and the actions of the brain are likewise of this kind. 2nd. Those actions which are of whole parts, and which vary according to their composition or construction, being employed chiefly respecting other matter, not for the immediate use of themselves, as in those above mentioned, but still absolutely necessary for the first. These actions are of whole parts, as the stomach, heart, organs of respiration, organs of sensation, mind and will. That these actions differ from the first is evident, because the organs in which they are found have also the first, and are indebted to the first for their existence, in the same way that the first are indebted to the second for their continuance: the stomach, lungs, heart, and other organs of life, may be said to be continually supplying materials with which the first are employed in building and repairing the system. The second kind may be called labourers, being subservient to the first, which, as being engaged in laying down and taking up parts, may be called the bricklayers. It is the first which compose the movements of the true animal, being those which are immediately employed about itself. It is the operations of these which properly constitute the animal economy, and it will be these which I shall principally consider.

The whole of the first kind of actions are involuntary, the will having no power over them, the mind being not even con-

scious of them, although it has, involuntarily, considerable influence over them, under circumstances of diseased and irregular action. Most of the actions of the second kind are subservient to the first, and are absolutely necessary to the continuation of their existence. These have therefore a certain degree of regularity, and according to the relationship or immediate necessity of the second to the first, are these second permanent and constant; indeed, we seldom find in them any intermission, perhaps never in health; though, in disease they are sometimes stopped. There have been instances where the motion of the heart has ceased, and also the involuntary action of breathing:—this once happened to myself.

I had the gout in my feet three springs successively, and missed it the fourth. In the fifth spring, one day at ten o'clock in the forenoon, I was attacked suddenly with a pain nearly about the pylorus: it was a pain peculiar to those parts, and became so violent that I tried every position to relieve myself, but could get no ease. I then took a tea-spoonful of tincture of rhubarb, with thirty drops of laudanum, but still found no relief. As I was walking about the room, I cast my eyes on a looking-glass, and observed my countenance pale, my lips white, and I had the appearance of a dead man looking at himself. This alarmed me. I could feel no pulse in either arm. The pain still continuing, I began to think it very serious. I found myself at times not breathing; and being afraid of death soon taking place if I did not breathe, I produced a voluntary action of breathing, working my lungs by the power of my will. I continued in this state three quarters of an hour, when the pain lessened, the pulse was felt, and involuntary breathing began to take place. During this state I took madeira, brandy, ginger, and other warm things; but I believe nothing did any good, as the return of health was very gradual. About two o'clock I was able to go about my business.

Here, then, was a suspension of the most material involuntary actions, so much so that the involuntary action of breathing stopped, while sensation and all the voluntary actions were as strong as before.

Quære: What would have been the consequence if I had not breathed? At the time, it struck me that I should have died; but that most probably would not have been the consequence, because, most

probably, breathing is only necessary for the blood when it is circulating; but as there was no circulation going on, so no good could have arisen from breathing.

The stomach appears to have been the seat of this affection. Affections of the stomach appear to have more influence on every part of the body than any other one part has on another; and this sympathy is reciprocal, for every part has a power of affecting the stomach, which shall be more fully treated of hereafter.

Of the second kind of actions, those which may be considered as having the nearest relationship to the first, are digestion, circulation, and respiration; these are all secondary actions of the machine. Those which are not so closely connected with the first, but respect more the actions of other parts of the same body, or what may be called remote parts of the animal economy, are the actions of muscles in moving the limbs, sensations, and voluntary actions employed on external objects, as progressive motion, mode of catching food, &c. We may just observe, that in a muscle itself, which has the power of moving other parts, we find the two kinds of actions; first, growth and support as in every other part; and, secondly, the action peculiar to the muscle itself. The first kind of actions arise immediately from the living principle, and have always been ranked as involuntary actions; the second are either involuntary, as the actions of whole organs,—the stomach, the heart, &c.—or are voluntary and dependent on the will, as common muscles, &c.: but these last I shall leave till I have spoken of the brain and nerves.

Besides this action in parts, which I have said is confined to muscles, there is another mode of action introduced, that of parts having the living principle which yet have not a power of self-action like muscles; these are the elastic ligaments.

The elasticity of these parts does not depend on life, for it exists equally in dead as in live parts. Ligaments are employed to assist muscles in keeping certain parts in their places, the position of which is long continued. They may be considered as producing a secondary action in the machine. These are more common in some parts in some animals than in others; such as the neck of quadrupeds, especially those with long necks, as the camel; and on the abdomen of some animals, as the elephant: this power is also introduced in the vascular system.

There are other parts introduced into

the machine which possess no action that can affect any other part, but have a kind of passive use in the machine. These vary in their consistence according to the uses made of them, some being extremely firm, as bones, tendons, &c., which sustain the actions of different parts of the animal, and without which it could not subsist; others are less firm, and are employed in uniting the various parts as cellular membrane.

From all that has been advanced, we see that by the juxtaposition or union of living parts organs are formed, which gives us the first mode of action, and the form of bodies gives the secondary mode. By the union of these various parts compound motion is produced. In this manner the whole of the most complicated animal machine is produced. The power of self action which animal and vegetable matter possesses, distinguishes it from matter endued with any other properties than life, and also distinguishes living from dead matter.

Of the Stomach.—Every animal body, however compounded, must have the means of support, especially as it is by gradual increase to complete its own magnitude. To this end the living parts fitted for preparing nourishment are thrown into the form of a bag, which is adapted for retaining the food; and this bag is endued with the power of secreting a matter which has the property of converting many vegetable, and all animal, substances into a homogeneous matter. This part is called the stomach, and in the less perfect animals it not only makes a considerable part of the whole animal in respect to size, but also in respect to its use in the machine, being the most considerable part of the whole. It may be considered as the first part of an animal, always becoming more and more simple as the animal becomes more simple; and also as the animal becomes more perfect, becoming proportionately the larger part of the animal.

The stomach is the distinguishing part between an animal and a vegetable; for we do not know any vegetable that has a stomach nor any animal without one. It is the converter of the food by hidden powers into part of ourselves, and is what may be called the true animal, no animal being without it; and in many, perhaps in most, it is what constitutes the principal part of an animal. A polypus is little more than stomach. An animal can exist without any senses, brain, or nervous system, without limbs, heart, or

circulation, in short, without any thing but a stomach. But for the continuance of the species you must have parts of generation; and a polypus is a stomach and parts of generation in one; and the complicating an animal is no more than adding other parts for various purposes. To one animal which has a brain and nervous system, you have ten thousand without them.

The power and operation of digestion is perhaps as curious a part of the animal economy as any whatever; at present, however, it is not for me to explain these operations, but it is necessary for me to take some notice of the connexion between this viscus and the animal economy in general; in doing which we shall find it to be as much the seat of universal stimulus and irritability as the brain is of sensibility. This connexion, as in the case of sensibility, is much greater in some parts than in others: the connexion that all the vital parts have with the stomach is much greater than between the others, which may be called voluntary, which is only saying in other words that the connexions among the vital parts is more immediate than between the vital parts and those which are not vital.

In diseases the brain seems to be intimately connected with the stomach, and *vice versâ*. It was as necessary for the stomach to be connected with the whole body as for the brain, although not in so marked a manner; but that it is as immediately connected with the body as the brain we may certainly assert. The affections of the stomach with the body are not so strong as those of the brain, the mind being made sensible of the least injury done to a part, while the stomach is not at all affected under many partial injuries of the body.

The stomach is more affected from the internal economy of the animal than from external influence, which is the reverse of the brain; for external influence in general can only be local, and local injury does not affect the stomach unless it be previously disturbed, or unless the injury is in certain parts, as the brain, the testes, and many of the vital organs, which, as I observed, have a more intimate connexion with the stomach.

The strongest natural affections of the stomach, as respects the body, are those connected with nutrition. These are of the greatest consequence in the machine, and may be said to be of two kinds, namely, want, and the contrary. Want

has often been known to produce madness: the contrary may be divided into two kinds,—repletion, and the want of health rendering nourishment unnecessary; and under such circumstances of the machine it is refused to be taken in. Perhaps repletion may be only a negative affection of the stomach with the body; the other is a positive one, and is often carried so far as to produce a sensation in the stomach, namely, sickness.

The stomach is affected by injuries in parts of the body which have no connexion with nutrition, and more especially with parts which have the least action in the machine. Although it may be difficult to understand why it should happen, yet we find that the stomach is more readily affected by injuries done to tendinous parts, and those which have little sensibility, than by injuries of muscular parts, especially of muscles under the control of the will. This is very remarkable in strains of tendons and ligaments.

The stomach is no less connected with the brain in the internal operations of that viscus concerning external objects or mental operations than in cases of real injury done to that part. A man cannot hear a horrible story or behold distressing circumstances but he will often experience sickness, vomiting, or purging, especially the latter.

The Vascular System.—In many animals, especially the more perfect, the nourishment, or whatever is taken into the system, is taken up and carried from the stomach to the heart, and from thence is thrown out to all parts of the system, through tubes; and from the system it is again returned to the heart by other tubes or vessels. It is absolutely necessary for the surgeon to have a tolerably clear idea of the operations of these vessels. The teaching of the structure and offices of these different vessels more properly belongs to the anatomist than to the surgeon; but as there is one use of the absorbent vessels not generally known, and which is of great importance in many local diseases, and has also an immediate connection with the original formation of the body, it will be necessary that I should explain this: at present, however, I shall do so but slightly, and trace the action more at large in speaking of local diseases. For the better understanding the whole action of the absorbents, it will not be improper to give a short sketch of the vascular system.

An animal body has in general been

considered under the idea of an hydraulic machine, because it appears to be almost wholly composed of tubes in which fluids move. I shall not at present enter into all the different opinions concerning the uses of these tubes, especially of that system called arteries; how they are variously affected, and how they produce their various actions, according to the different stimuli either of health or disease; but shall only give some general ideas of the most important uses of the three different sets of vessels, namely, arteries, veins, and absorbents.

Arteries.—These carry the blood from the general reservoir, the heart, to all the different parts of the body; the veins return it to the heart. The arteries constantly dispose of a part of the fluid which they contain in the different operations of the body, according to the different functions of the parts: adding to the whole where growth is necessary; making up losses where the whole is either improper or destroyed; and throwing out of the direct line of motion parts of that fluid, which, according to the different affections and actions of these arteries, become considerably altered in the process: this is called secretion.

Juices so secreted are intended for various purposes in the machine; some for stimulants, as the bile; some for mechanical purposes, as the tears, synovia, saliva, &c.; some for a store of nourishment, as the fat, &c.; while others are thrown out of the body as useless, because they have already performed all their purposes, as the urine, &c.

Veins.—The other set of vessels, the veins, are considered as less active, being principally employed in bringing back the red part of the blood, after it has lost its most salutary parts, or done those offices, whatever they are, for which it was sent out. This, of carrying back red blood, was not considered as the only office of the veins; many of their beginnings were supposed to arise, not from the terminations of arteries, but from most if not all the surfaces of the body, internal and external: making so many inlets into the general system, and bringing matter into the common mass of fluid for the support of the whole, and also to bring back many of the parts secreted by the arteries from the blood for the different purposes of the machine, such as synovia and lubricating fluids of all kinds; which fluids, having answered their different purposes, and having become unfit for every other use in the

machine, were obliged to be brought back again into the circulation, to be changed in the lungs and again thrown out of the circulation by the arteries.

Absorbents.—Such were considered to be the uses of the veins before the discovery of the lacteals; but by the discovery of these they were deprived of part of their supposed offices, namely, that of absorbing the chyle; still they were thought to absorb matter from the cavity of the intestines for the secretion of bile. The other part of the absorbent system, called the lymphatics, though long known, was not in the least suspected of performing the operation of absorption, but was still supposed to be the terminations of the extreme ends of the arteries, not large enough to carry red blood but only serum or lymph; though from their similarity to the lacteals, which were known to be absorbents, it became at last evident to common sense that they must absorb.

Before this idea was started, the general opinion of the vascular system ran thus. The arteries were supposed to carry blood for nourishment, secretion, &c. throughout the machine; the veins to return the red blood, as also to absorb from every surface of the body; the lymphatics to return the lymph or blood which came along the arteries: and the lacteals to absorb part of the chyle from the intestines.

But some experiments which I made to ascertain whether the veins of the mesentery absorbed, proved that they had not the power of absorption. I do not suppose the veins, even in an erection of the penis, to have the power of absorption; but I consider the corpora cavernosa as veins through which the blood is constantly flowing from the arteries, and that other veins carry off the blood from the corpora cavernosa: that in erection there is a spasm on the extremities of these veins, which prevents the blood from flowing into them, in consequence of which an accumulation and distension takes place, which causes an erection, and this ceases with the spasms on the veins. By tying the veins of a dog's penis, I found I could cause an erection at pleasure, while the arteries continued free. Now, therefore, the offices of the three systems of vessels were as follow. The arteries remain as before; the veins reconvey the blood to the heart, for a continuance of the actions of the arteries as before, but have lost their supposed power of absorbing; the absorbents alone are employed to take up whatever is to

be carried into the circulating system. Now let us consider what are the substances always allowed to be absorbed. 1st, Extraneous matter, in which is included nourishment. 2nd, Secreted, superfluous and extravasated matter, whether natural or diseased. 3rd, The fat. 4th, That portion of parts which, being absorbed, causes the waste of parts, as muscles becoming smaller, bones lighter, &c. Although these two last effects were perhaps not expressly said to be carried on by absorption, either by the veins or the other system of vessels, yet we must suppose it was understood.

So far the absorbents have been considered as an active part in the animal oeconomy; but, from a further knowledge of these vessels, we shall find that they are of much more consequence in the body than has been imagined, and that they are often taking down what arteries had formerly built up, thus becoming modellers of the body; and that they are also removing many diseased parts, which were beyond the power of cure.

As these vessels are productive of a vast variety of effects in the animal oeconomy, which are very dissimilar in their intention and effects, they may be viewed in a variety of lights, and admit of a variety of divisions. We shall first consider them under two views. 1st, As absorbing matter which is not part of the machine. 2nd, As absorbing the machine itself.

The first is a well-known office of the absorbents, and is of two kinds; 1st, the absorption of exterior matter, in which may be ranked everything that is applied to the skin, as also the chyle. 2nd, The absorption of interior matter, such as many of the secreted fluids, the fat, the earth of bones, &c. It may be necessary to observe that I do not consider the fat and earth of bones as part of the animal, as they have no action within themselves, and have not the principle of life.

These actions of absorption are principally employed with a view to the nourishment of the animal, as also to answer many other purposes, as in the absorption of foreign matter, which is extremely extensive and is very important: for, besides its salutary effects, it is often the cause of a thousand diseases, especially from poisons; all which are not to our present purposes.

The second office of the absorbents which we are to consider is that of removing parts of the body itself, which

may be of two kinds. The first of these is where only a gradual wasting is produced, either of the whole machine, as in atrophy, or of a part, as in the muscles of a leg or arm, from an injury done to a nerve, tendinous part, or joint: this I call interstitial absorption, because it is the removing a part of the body out of that part which remains, leaving the part still a whole or complete part; a muscle, for instance, that is wasted remains still a perfect muscle. The second is where the absorbents are removing whole parts of the body, and this may be divided into natural and diseased. In the natural, these vessels are to be considered as the modellers of the original construction of the body; and if we were to consider them fully in this view, we should find that no alteration can take place in the original formation of many parts, either in natural growths or in parts arising from disease, without the absorbents being in action to take a considerable part in it. This kind of absorption I shall call modelling absorption. If I was to consider this function in these lights, it would lead me to a vast variety of facts, as extensive as those connected with any principle in the animal œconomy, for bones cannot be formed without it, nor probably many other parts.

A part which was of use in one stage of life, and becomes entirely useless in another, is removed. This is evident in many animals: the thymus gland is removed, the ductus arteriosus and membrana pupillaris are removed. This process is perhaps more remarkable in the changes of insects than in any other animals. The changes in an insect are very curious. The insect is first a maggot or caterpillar, then goes into the chrysalis state, and comes out a butterfly. Whilst in the chrysalis state it is totally changed, the old parts are almost wholly taken up, and new parts formed: and it is this modelling process that occasions these changes.

Bones do not grow by having new particles put into the interstices of previously formed parts, so as to remove these to a greater distance from each other, by which means they should grow larger,—as, for instance, if I put a sponge into water, the water getting into all the interstices, makes it larger,—but they grow by the addition of new bone on the external surface.

I took a pig of a very large breed when young, bored two holes in the tibia, and put a shot into each, measuring on a card

the distance of each from the other. I allowed this pig to grow up to its full size, then killed it and took out the bone, and I found the two holes at exactly the same distance from one another as at first. Now if the bone had grown in all its parts, these two shot would have been removed to a distance from each other proportionate to the growth of the bone.

This fact is also ascertained by feeding animals on madder at different intervals, by which means we shall get strata of red and white bone.

Since we know that bones do not grow by fresh matter being put into all parts, so as to push the old matter to a greater distance, but by new matter laid upon the external surface, let us see whether it is possible for bone to grow and retain its form without being taken down. We take the head of the thigh-bone of a fœtus. Now if the increase was accomplished by superimposed layers, one over the other, the head of the bone would necessarily become of an enormous size, and in time would come down so as to occupy the middle of the bone, while the cavity in the centre would not be enlarged. Absorption, therefore, must necessarily go on to keep the bone of its proper shape. Hence I call this the modelling process, for without this combined action of absorption and deposition the animal could not grow as it now does.

The absorbents possess the power of removing complete parts of the body, in consequence of disease, an operation which is somewhat similar to the first of this division, or the modelling process, but very different in the intention, and therefore in the ultimate effect. This process of removing whole parts, in consequence of disease, in some cases produces effects unlike what it produces in others, one of which is a sore or ulcer; in other cases no sore or ulcer is produced, although the whole part is removed. The first I call ulcerative absorption; but for the other I have not been able to find a term.

This process of the removal of a whole solid part of the body, or that power which the animal œconomy possesses of taking part of itself into the circulation by the absorbent vessels when necessary, is a fact that has not been in the least attended to, nor even been supposed possible; and as I now mean to give a general idea of it, I may just be allowed once more to observe, that the oil or fat of the animal, and the earth of bones, have always been considered as subject to

absorption, and some other parts of the body most liable to waste have been supposed to suffer by absorption; but that any solid part should be totally absorbed is a new doctrine. The use of the absorbents I have been able to demonstrate. The first hint I received of it was in the waste of the sockets of the teeth, and also of the fangs of the shedding teeth, which was in the years 1754 and 1755 (see *Treatise on the Teeth*, first and second parts.) This opinion was strengthened by what I observed in the process going on in the exfoliation of bones.

It may be difficult to conceive how part of the body should remove itself, but it is just as difficult to conceive how the body can form itself. They are both equally facts. The knowledge of their mode of action would perhaps answer but little purpose.

This, at least, I may assert, that when any solid part of the body undergoes diminution, brought on in consequence of disease, it is the absorbent system that has done it; the absorbents are the thieves.

The remote cause of absorption of whole and living parts implies the existence of two conditions, the first of which is a consciousness, in the part to be absorbed, of the unfitness or impossibility of remaining under such circumstances, whatever they be, and therefore they become ready for removal, and submit to it with ease. The second is a consciousness of the absorbents of such a state of the parts. Both these concurring, they have nothing to do but to fall to the work.

Now the part that is to be absorbed is alive, it must feel its own inefficacy and admit of absorption. The vessels must have the stimulus of imperfection of this part, as if they were sensible that this part were unfit; therefore take it up. There must be a sensation in both parts.

When the matter to be absorbed is a dead part, as nourishment and extraneous matter of all kinds, then the whole disposition is in the absorbents.

This is the only mode in which this power is capable of producing such effects, and, like all other operations of the machine, arises from either stimulus or irritation, all the other modes of destruction being either mechanical or chemical.

The knowledge of the use of the absorbent vessels is of late date, and the knowledge of their different modes of action still later. Physiologists have endeavoured to account for their modes of

action on the principle of capillary tubes at their beginning, and this is the most common notion, because it is a familiar one. But this is too confined an idea for an animal machine; nor can it account for every kind of absorption. But as solids are often absorbed, as indurated tumours, coagulated blood, earth of bones, &c., they were driven to the necessity of supposing a solvent. This may or may not be so; it is one of those hypotheses that can neither be proved nor disproved, and must for ever rest as an opinion. My idea is, however, that nature leaves as little as possible to chance alone, and that the whole operation of absorption is performed by one action in the mouths of the absorbents.

But even under the idea of capillary tubes, physiologists were obliged still to have recourse to the actions of these vessels, to carry on the matter absorbed; therefore they might as well have extended the action to the mouths of the vessels.

As we know nothing of the mouths of these vessels, it is impossible we can form any opinion that can be relied on; but as they are capable of absorbing substances in a state of solidity and fluidity, it is reasonable to suppose that they have different modes of action; for although any construction of parts that is capable of absorbing a solid may also be such as is capable of absorbing a fluid, yet I can suppose a construction capable of absorbing a fluid that is not fitted for the absorption of a solid, though this is not likely.

To see the possible correctness of this notion more forcibly, let us only recollect the variety in the mouths of different animals, and I will venture to say that the mouths of all the different animals have not a greater variety of substances to work upon than the absorbents have; and it may be observed, that with all the variety in the mouths of different animals, this variety is only for the purpose of adapting them to the forms of solids, which admit of great variety, every one being capable of absorbing fluids, which admit of no variety.

I have often said, on this point, that if we could see the mouths of these vessels, we might perhaps class the modes of absorption as animals have been classed, by their teeth, &c.

Matter taken into the constitution by the absorbents is capable of being altered in its nature from what it was out of the constitution. Although this may have

been conjectured or imagined, it never has been absolutely known, and even now the only proof we have of it is the change produced in venereal matter. If the matter of chancre or gonorrhœa be absorbed, it produces disease: this disease is not similar to the original; it is not pocky matter which is produced from the ulcers, but this matter has been changed from its original nature in the circulation; although the change was of such a kind as still to retain its power of stimulating and producing disease: but as it was changed, the disease produced was not similar to that from whence it came.

That there is a change in venereal matter is very evident, for if venereal matter out of the constitution be applied to a living part, it always produces an effect according to the nature of the part, which part may be of two kinds, either, 1st, a secreting surface, producing then gonorrhœa; or, 2nd, a non-secreting surface, producing then a chancre.

That this process of altering substances in the constitution is not a universal principle and common effect of all kinds of matter which enter the circulation, is evident; for we do not as yet know, for certain, of any other matter being altered.

TABLE OF ABSORPTION.

Absorption connected with growth.	Absorption for nourishment.	Extraneous matter to become useful, as chyle, fat, &c. Interstitial absorption of parts of the body itself, as cellular membrane, muscles, &c.
	Absorption of useless, inconvenient, or hurtful parts.	Extraneous, that have been useful, as synovia and other secretions, become useless.
		Parts of the body itself.
		Producing wasting of a part, as a leg, an arm, &c.; or wasting of the whole body.
Absorption in consequence of disease.		Absorption of the whole parts.
		As modellers in the time of growth.
		In consequence of weakness, as in the removal of calluses.
		From parts becoming wholly useless, as the alveoli.
	Interstitial absorption.	Partial wasting of a leg, an arm, &c.; or of the whole body, as in atrophy.
		Total wasting of a callus, of a testicle.
		As when pus or any extraneous body is brought to the skin.
	Progressive absorption.	In the process of exfoliation of bones.
		In the process of sloughing.
		In the formation of ulcers.
		In the removal of the fangs of the teeth.
	Mixed.	As the progress of pus, tumours, &c. to the skin.
		Attended with supuration.

A PRACTICAL VIEW
OF
LITHOTRITY:
WITH REMARKS ON
THE LATERAL OPERATION OF
LITHOTOMY.

BY MR. ASTON KEY.

(Continued from page 237.)

Setting aside hæmorrhage, the injury inflicted on the neck of the bladder and prostate gland gives rise to the most formidable danger that attends lithotomy. In this respect it resembles lithotritry; for in both operations it is the violence done

to the neck of the bladder that destroys the patient, in the majority of fatal cases. It is the manner in which the injury is inflicted that constitutes the danger. If we may judge from experience, the prostate gland would appear to sustain without inconvenience the effect of laceration: and this the experienced lithotomist bears in mind, in the act of extracting the stone. But contusion is most disastrous in its effects: it appears to cause sloughing, and diffuse inflammation of a destructive character in the neighbouring structures. In making the incision, and in extracting the stone, the object of the operator should be, to make a sufficient aperture to allow the stone to pass without bruising the gland; and not to carry

the knife too far laterally, so as to divide the deep perineal fascia, and thus expose the cellular basin of the pelvis. The knife, if used incautiously, exposes the patient to this danger. If the prostate be large, and the stone of considerable size, a large aperture is required; and if the substance of the gland be indurated, the lips of the incision do not yield. To obviate these inconveniences, the surgeon carries the knife more freely through the prostate, and thus adds to the risk of opening the deep fascia that of hæmorrhage from the arteries of the gland. Under these circumstances, I always look to the assistance which the blunt gorget affords, as obviating both the difficulties, without inflicting an injury of a serious kind upon the gland. This instrument, in the hands of the late Mr. Martineau, has had its merits fully tried; and its success is sufficient answer to any objection that can be urged against it. His object, in this part of the operation, was three-fold—to make a small incision in the gland with the knife; to enlarge the incision with the blade of the blunt gorget; and to take time in drawing the stone from the bladder. In so conducting the operation, the gland is not bruised, but torn: the slow introduction of the blunt gorget separates the fibres of the gland, and enlarges the incision as far as the deep fascia, without dividing it; for the fascia yields, and stretches, as the gorget enters the bladder. Sudden violence, in the act of introducing the gorget, is nearly as much to be deprecated as the violent extraction of the stone. The kind of violence which the blunt gorget, properly employed, inflicts, is well borne by the gland, and symptoms of high inflammation are rare, after such an operation.

The extraction of the stone is attended with more hazard to the gland. A nervous or a violent operator, feeling some resistance to his efforts, redoubles them, until he finds the stone obeying the force that he employs. If the opening in the gland be made with a cutting instrument alone, and be small, the stone is brought with difficulty into the incision, as the lips of the wound do not open. Additional force is then employed; and the operator, in ignorance of what he is doing, drags the gland before the stone, separates it from its attachment to the deep fascia, and brings it nearly to the external aperture before his efforts succeed. The consequence of such an injudicious proceeding is, to bruise the

gland, to cause it to slough, and to render infiltration of urine almost inevitable, by the laceration of the deep prostatic connexions. The danger is, in part, prevented by the use of a broad blunt gorget, which enables the broad end of a large stone to enter the incision; and renders it obedient to the gentle but continued force of the surgeon. In this step of the operation, time must be given for the parts that embrace the stone to dilate: the muscular structure at the neck of the bladder, the firm substance of the prostate gland, and the deep fascia, will each stretch, and yield to the sustained efforts of a firm but gentle hand. In cases of enlarged and hard prostate, I have occasionally opened the incision while passing the forceps through the prostate, by separating the blades in a vertical direction: this, however, should be done without violence.

The gland is sometimes injured in withdrawing the stone, by the forceps embracing a portion of it, and tearing it away from the body. This accident happens when the central portion of the gland, or, as it is termed, the third lobe, is enlarged, and presents a narrow ridge at the entrance of the bladder. The forceps, where the blades diverge, close on this projection, as they embrace the stone; and the operator is unaware of it, until a piece of the gland is brought away in the blades. It may be avoided, by passing the finger below the forceps, and disengaging the gland from the forceps after the stone is seized. In my operations, I always pass the left fore-finger along the staff, after the knife is withdrawn; and reconnoitre the size of the incision, the texture and form of the gland, and situation of the stone. If the finger feels a projecting portion of gland that rises between the blades of the forceps as they are opened laterally, care should be taken to prevent it being entangled, by depressing it as the stone is brought forward. As soon as the stone enters the incision, the danger is past. I do not, however, wish to magnify the extent of this danger; for, in truth, it is less than might be expected. The injured portion is brought away, and not left to slough; and the surface from which it is brought is a lacerated wound, without contusion. In one case, that of an elderly gentleman, it happened to myself in operating; but the patient, after suffering for a few days with irritative fever, ultimately did well: and I have observed, in the few cases that have oc-

curring in the operations of other surgeons, that a slight degree only of fever, with fetid urine, has been the consequence, and in a few days has passed away. The neck of the bladder becomes slightly inflamed; but the incision prevents the ordinary severe effects of cystitis, by allowing the urine to drain away—an advantage that lithotripsy does not possess.

The body of the prostate may receive injury from being grasped in the forceps, by the operator expanding the blades before they are fairly in the bladder. One blade slips beneath the lobe, while the other enters the bladder; and the operator, on closing them, thinking that they embrace the stone, uses considerable force in his attempt to extract it. The contusion and pressure which the gland undergoes are sufficient to induce inflammation, and, probably, some of its worst consequences.

In many, or perhaps most, of the fatal cases of lithotomy, inflammation of the peritoneum, investing the fundus of the bladder, is found to exist to a greater or less extent. In some few cases, it is of sufficient intensity to cause the destruction of life; but even where the mischief about the neck of the bladder is evidently of itself the cause of death, the peritoneum often partakes of the morbid action. This disposition of the peritoneum to participate in the inflammation of the perineal structure is not confined to the operation of lithotomy, but manifests itself in other operations on the perineum. In the opening of the membranous part of the urethra for stricture, where the cellular membrane and muscles of the perineum are divided, it is not uncommon to find the patient labouring, in a few days, under a sharp attack of peritonitis; and, in some instances, under a fatal form of the disease. The action appears to be propagated by the cellular membrane of the perineum to the peritoneum. On examination after death, the continuity of the inflammation, or at least its effects, cannot be discovered in the reticular tissue; but the most probable explanation of the frequent connexion between the morbid states of the two parts is the continuity of action. This is one source of danger to which the wound in the perineum exposes the patient.

Lithotomy is altogether free from the risk of leaving fragments in the bladder, where ordinary care is taken to examine the cavity, and to wash out whatever fragments may have been occasioned by

the accidental breaking of the stone. If a fragment or two remain behind, they usually pass through the wound by the fourth day, when the tumefaction occasioned by incision has subsided; and clots of blood are rarely retained for any length of time. These often collect in the bladder, through the oozing from the prostatic vessels; but occasion sufficient irritation to induce the bladder to expel them. The patient may be rendered very uneasy after the operation, by a sense of distension in the region of the bladder, and of bearing down in the perineum; which continues until the repeated efforts of the bladder expel some small masses of coagula: or, if the distress be great soon after the patient is put to bed, and continues toward the evening, it is often found to arise from coagula obstructing the flow of urine; and the gentle introduction of the finger along the wound is followed by a copious discharge of urine mixed with coagula.

I will not omit the danger attending a wound of the rectum, though I cannot attach much importance to it. It appears to me, that undue importance is given to the accident. It is a very rare occurrence, so far as my experience extends. Among all the operations that I have witnessed, I have only once known the rectum to be wounded, and then without the supervention of any untoward circumstance. It occurs usually, I apprehend, in making the second deep incision, in reaching the groove of the staff; or in dilating this incision after the groove is exposed. In doing this, the operator carries his knife more freely downwards, to divide the transverse muscles of the perineum and the fascia that reaches to the levator ani; and if the rectum be distended with air or feces, the knife may easily open it. When other sources of danger and irritation exist, such an additional evil adds to the aggregate of the danger; but, taken by itself, the wound of the bowel, occurring as it does close to the sphincter, is a matter of no serious moment.

The after-consequences of the operation of an untoward kind may be summed up in the accidents of fistula in perinæo, impotency, and incontinence of urine. The first I have not witnessed as a consequence of the operation for vesical calculus. The operation of extracting prostatic calculi, when they are large and the gland diseased, is sometimes followed by difficulty in healing the external incision; and the formation of a fistula, through

which some drops of urine escape. But in lithotomy, the incision, being made through healthy structures, heals quickly, by a healthy process of granulation; and fistula is, therefore, a very uncommon occurrence. In a gentleman verging upon eighty years of age, whom I cut about three years since, an abscess formed in the prostate gland, and burst into the rectum. Benefit, rather than inconvenience, followed this; for the prostate, being very much enlarged, had obstructed the free escape of urine from the bladder, and partial retention often occurred: the aperture into the rectum remedied the difficulty, by allowing the bladder to empty itself more completely; and was otherwise of little inconvenience to him. The external wound healed in the usual manner. Impotency I have known to occur, in one instance: at least, it was attributed to the operation by the patient, who was otherwise a healthy person. Incontinence of urine rarely occurs in the adult, according to my experience. In the young subject, partial incontinence will sometimes occur, if the patient is allowed to leave his bed too soon after the operation, before the neck of the bladder is firmly healed, and the sphincter has recovered its tone. Instances, therefore, are met with, of young boys, who, if they retain their water inconveniently long, find it dribble away as they move about. In bed, the urine is perfectly retained. When they arrive at the age of puberty, the power of retaining it becomes increased.

The preceding sketch will serve to bring before the surgeon the several difficulties which surround lithotomy; and to remind him, that although, in the hands of English surgeons, it is a most successful operation, it nevertheless has dangers, for which he cannot be wholly prepared, and against which he cannot with certainty guard. Were it possible to foresee the occurrence of hæmorrhage, and its effects on the constitution of the individual—and, when it does occur, to arrest it with ease and certainty—the operation would be divested of one half of its risk. Or, if the causes of inflammation could be seen and warded off by any previous management, and all constitutional infirmity remedied, the lithotomist would have little to fear. But no experience, however great, can enable us to foresee the perils that suddenly arise, in the midst of apparent security. Judicious preparation of the patient, by regimen and medicine, may diminish his

sensibility and disposition to inflammation; but the unexpected results of cases teach us that there are unknown causes in operation that prostrate the patient's powers, even when he appears to be in the most favourable state for the operation, and the utmost skill is employed in the performance of it. In the knowledge that we have of coming danger, the balance is much on the side of lithotrixy.

In the observations that I shall make on lithotrixy, I shall consider the circumstances that render it practicable, the mode of performing it, and the dangers attending it: and having described the several steps of the operation, I shall endeavour to lay down some rules to assist in determining which operation is more eligible, in each particular case.

To the discovery of the calculus in its earliest stage, I have already adverted, as one of the greatest benefits conferred by lithotrixy; and the very first intimation of the presence of a stone in the bladder should not be neglected. The symptoms of its existence are too well known, and have been too often described, to require a repetition of them here. The previous occurrence of a nephritic attack, and the descent of a stone through the ureter, should lead us to look for some vesical symptoms occasioned by the attempt of a small calculus to enter the urethra. A stone, when it has descended into the bladder, is usually of very small size, and causes scarcely any noticeable sensation in the act of micturition; it often lies quiet in the base of the bladder for some weeks, until, by its continual presence, irritation is produced, and forcible and repeated efforts to expel it are made after each evacuation of the urine. The pain which the patient suffers results not so much from the contraction of the viscus on the stone, as from the force with which it is pushed towards the orifice of the urethra, and the consequent spasmodic action of the muscles at the cervix. Sometimes the stone becomes partly impacted in the orifice of the urethra, and gives the patient excruciating pain, until the contraction of the bladder ceases, and the stone again falls back into its cavity. The sufferings in this way occasioned by a very small calculus are often greater than when the stone is larger, until inflammation arises at the neck of the bladder, and then the pain becomes much aggravated. A stone, when it first begins to occasion symptoms, is usually not larger than a small horse-bean; and the smallness of its size often occasions it to

elude an examination of the bladder, imperfectly or hastily conducted.

The operation of sounding has been rendered much more exact by the assistance afforded by Heurteloup's bed. Had this expert lithotritist contributed nothing else to the operation, lithotripsy would be greatly indebted to him. The certainty with which the presence of a stone may be ascertained, be it ever so small, will not fail to strike a surgeon accustomed to the former inexact method of sounding. A common sound introduced into the bladder of an adult with a full-sized prostate gland can with difficulty be brought in contact with a small stone lying in the hollow of the bladder behind the gland, especially if there be a few ounces of water collected in the cavity. The convex part of the beak cannot, by any ingenuity, be so turned or moved in the bladder as to reach it; and the patient is pronounced to have not a stone until it increases in size, and acquires magnitude sufficient to meet the sound. The important period is thus lost; one seizure of a stone so small would be sufficient to crush it; but the imperfect manner of conducting the examination, in too many instances, leads the surgeon to form an erroneous opinion. These difficulties are wholly obviated by the lithotritic bed; which in addition to its utility in the operation of crushing the stone, enables us to detect its presence in the earliest stage, and even to ascertain its size with a great degree of precision. For the purpose of examination, the bladder should be neither quite empty, nor should it contain a large quantity of water. The former state is, of the two, the less objectionable; for the stone is sometimes met with at the entrance of the bladder, when the latter is empty; and its presence is at once recognised by a sharp tap against it, as the sound enters the bladder. But it is more desirable to have a small quantity of water in the bladder, as the stone can be both felt and examined as to its physical qualities. The inconvenience of a large quantity of water may be experienced in the following manner. If the patient lie on a sofa, and about two ounces of water be injected through the catheter, the stone will generally be felt at the lower part of the bladder, and its size and depth may often be pretty accurately ascertained: if two or three more ounces of water be injected, the stone sinks down into the base of the bladder, and its upper surface can alone be felt, and that

imperfectly: if the quantity of water be increased by a further injection of three or four ounces more, the stone sinks wholly below the level of the instrument, and altogether eludes it. This arises from the peculiar manner in which the bladder dilates, as water accumulates in its cavity; of which I shall have occasion to speak more particularly. The operator may think, that the more water the bladder is made to contain, the more easy will be his examination; the motion of the instrument being more free in a large than in a small cavity. The quantity of water should, indeed, be sufficient to allow the short beak of the catheter to move freely, in a lateral direction: about three ounces will be sufficient in an ordinary bladder; but, in order to make the examination more satisfactory, the stone should be dislodged from behind the prostate, by suddenly inclining the patient backward, and altering the axis of the bladder: this is effected by the couch or chair.

The London Medical

AND

Surgical Journal.

Saturday, June 3rd, 1837.

THE METROPOLITAN UNIVERSITY.

The organization of the New London University is advancing as rapidly and as satisfactorily as could have been reasonably anticipated by its most ardent well-wishers. From the discordant elements of which the Senate was necessarily composed, it was fully anticipated, that the representatives of the corruptionists, who were admitted, though in a small proportion, into that body, would use all their efforts to oppose every measure which, from its liberality, would be likely to give general satisfaction to the public

T

mind, and thus encroach on the old rotten establishments. The pertinacious and inflexible opposition of Dr. Peter Mark Roget to every recommendation of Mr. Warburton, affords us a gratifying, though lamentable proof, of the forebodings which we ventured to predict of the conduct of that eminent physiologist, and no less distinguished philosopher. We had no hesitation in formerly stating that there were two distinct and very opposite opinions entertained, as to the propriety of electing Dr. Peter Mark Roget; at the same time, we were decidedly of opinion, that it would be of essential service, more particularly whilst the New University was in its infancy, to admit a few individuals, a chosen few, whose principles and conduct had ever been in direct opposition to those of the New Establishment, and, therefore, we considered Dr. Peter Mark Roget as an individual pre-eminently qualified to advocate the sentiments, and propound the doctrines of that sect, appropriately denominated ultra-corruptionists. In these hopes we have not been disappointed, and the meetings of the Senate of the New University have had ample testimony of his talents and zeal in the great cause which he has undertaken to support. In accomplishing his important projects, Dr. Peter Mark Roget has been ably assisted by only four partisans in his boldest measures, though, in those of minor importance, he had the co-operation of occasionally pliable and less determined characters. Besides, the learned Doctor of Laws, and President of the College of Bristol, the ROGET DILLY contained as inside passengers Dr. James Clark, and Dr. Neil Arnott, whose naval tactics rendered them particularly useful in all arduous navigations.

There is no point on which Dr. Roget has more strenuously, and less success-

fully, combatted the measures of the enlightened members of the Senate, than in the opposition which he and his liberal phalanx have offered to the *open* manner in which business of the University was to be conducted; and it will be scarcely credited that the Secretary of the Royal Society made use of every argument to convince the Senate that all matters concerning the University should be executed by SECRET COMMITTEES. We cannot help expressing our opinion that the very proposal of such measures, and by such individuals, will have the most salutary effect; and that it is fortunate a member of the Senate should have been discovered, and been induced to have become one of its body, who had a sufficient quantity of moral courage to bring such monstrous propositions before the Council of a University established in the Metropolis of the British Dominions, in the year of our Lord ONE THOUSAND EIGHT HUNDRED and THIRTY-SEVEN.

However judicious the Chancellor of the Exchequer may have been, when selecting the different individuals who composed the Senate, and of making that selection from amongst those, not only different political, as well as religious creeds, but also of introducing some remnants of the old corruptionists; and, although, on reducing the list, the poisonous materials contained in it appear to form but a small proportion to the antidote which is introduced; yet an event has occurred which, though of minor importance, shows the necessity of watching with a vigilant eye every movement of the Roget Dilly. The medical profession will be astonished, though they may not altogether be disappointed, that in the selection of the members of the Medical Senate of the New University the name of Mr. Warburton has been excluded; an object which was attained by one of those

skilful manœuvres, which will occasionally take place, unless the fraudulent purposes of certain intriguing members of the Senate be not frustrated by the more liberal and enlightened members of this National Institution.

AN ADDRESS

DELIVERED TO THE MEMBERS OF THE

WORCESTERSHIRE

NATURAL HISTORY SOCIETY,

ON THE OPENING OF THE

WORCESTERSHIRE MUSEUM,

SEPTEMBER 15, 1836.

BY CHARLES HASTINGS, M.D. F.G.S.

(Continued from page 232.)

We may pause a little to reflect on the character of Ray, who may be selected as one of a host of naturalists who considered it to be among the noblest ends of Natural History to generate in the mind of man love and veneration for the Creator, and admiration of the beauty and sublimity of his works. His "Wisdom of God manifested in the Works of Creation" was the first attempt ever made in the Christian era to confirm the truths of revealed religion, by facts drawn from the natural world. He was the friend and companion of Willughby, and their works were many of them carried on together. They were among the earliest Fellows of the Royal Society of London, a Society which may be said to have introduced the study of Natural History, as a science into England.

I might here dwell upon the labours of other naturalists, who, about this time, enriched the volume of Natural History; but it is impossible in this short sketch to do more than allude to the general results of the works of the most distinguished of them.

The most prominent of these stands the imperishable name of Linnæus, a man who, with some faults, possessed in so high a degree the intellectual and moral endowments which give dignity to man, that for ages yet to come he must be regarded as one of the benefactors of the

human race. So great is his fame that it may be placed in competition with that of Aristotle and Bacon. His admirers may perhaps, in some instances, have gone too far in praise of his system, and may have too servilely followed his precepts, a result which has led several of late years to undervalue the exertions of Linnæus: but we may venture to predict, that so long as the study of nature finds admirers, so long will the ardent and zealous exertions of the Swedish naturalist exact from succeeding generations the tribute of just applause. Before the Society I now address, who annually assemble to declare the honour due to him, by making his natal day their anniversary, I need not insist upon the gratitude due to departed greatness; but the occasion seems to call forth an expression, feeble though it may be, of those feelings of admiration which must necessarily spring up in every enlightened mind, when reflecting on the brilliant career of the Swedish philosopher.

Charles Linné, or as he is now generally called, Linnæus, was born on May 24th, 1707, in a village called Roeskult in Smaland, where his father Nicholas Linné was then vicar. Charles was destined for the church, but he early showed so decided a taste for natural history, that he was educated as a physician. Being entirely destitute of fortune, he had to contend with very great difficulties, and his early life is one continued history of laborious exertion in the pursuit of the favourite science which he ardently loved. Who can read the account of the interesting, perilous, and fatiguing journey, made by Linnæus on foot, through the whole of Lapland as far as the Frozen Ocean, without being penetrated with feelings of admiration for the undaunted and unconquerable spirit with which he overcame all obstacles, or without experiencing a glow of satisfaction at the success with which the labours of this young adventurer were crowned.

Pursuing his course onward in life, we find his merits as a naturalist duly appreciated by his contemporaries. He did not graduate as a physician until 1735; about which time he published the celebrated work upon which his fame principally rests, the *Systema Nature*. By this it appears that he had, before he was twenty-four years old, laid the basis of that structure which he afterwards erected to the increase of his own fame as well as of natural science.

The system of Linnæus was, in one

sense, confessedly artificial. He divided vegetables or plants in twenty-four classes, according to the number, the insertion, the comparative length, the union, or separation of the stamina. This arrangement brought together many discordant species: it has nevertheless been found to be admirably adapted to facilitate the knowledge of plants.

After the appearance of this great work, the fame of Linnæus became European, and in 1736 he visited England, where he was received with distinction, and became acquainted with Dillenius, Martyn, Rand, Miller, Lawson, and Collinson, who were then successful cultivators of his favourite science in this country.

After this time he was favourably noticed by almost every scientific body in Europe; and in 1757, his reputation having then procured for him honours from almost all the Royal Societies in Europe, Adolphus Frederic created him a noble of Sweden. His successor, Gustavus III. doubled his pension in 1776, and settled a liberal donation of landed property on his family. Thus we see the persevering Swede, who began life in poverty and neglect, by the influence of exertions, greater than we can often find related in the biography of great men, raised himself to be the companion of princes, and to a fame which the passing away of a century has rather tended to increase than diminish.

Doubtless there were many things in the state of Natural History at the time that Linnæus became its zealous cultivator, which were favourable to the reformation in the science, which he was the means of effecting. We must not forget that the horizon of science had been illuminated by the brightness cast upon it by Bacon. Dr. Grew had by this time published his catalogue of the Museum of the Royal Society, which showed how zealously Natural History was then cultivated by that learned body. Sir Hans Sloane had also formed his celebrated museum, and Bradley, Fermin, Klein, Knorr, Renard, Brown, and others of inferior note had each done something to advance the progress of our science. But taking all these things into account, and giving to those who have preceded him their just meed of applause, we must admit that the services which Linnæus rendered natural history, at the time he wrote, were immense, and will never be forgotten. His unrivalled invention of nomenclature, which came from his hands, as it were, perfect, will remain of

undiminished value so long as science exists, while, to use the words of Mr. Swainson, the simplicity of those rules by which he arranged all the productions of nature then known, cannot be too closely imitated, however different may be the series in which these productions are disposed.

Naturalists were surprised and delighted with the luminous order in which Linnæus arranged his information, and thus he insured for his science many admirers, who duly appreciated a system which required from them no previous study to reveal the beauties of nature. Thus natural history arose in Sweden, under his culture, to a state of perfection unknown elsewhere, and was thence disseminated through all Europe.

Nearly contemporary with Linnæus, but certainly much his inferior in those solid endowments which are necessary to form the scientific naturalist, was the Count de Buffon. He was born at Montbard in Burgundy, the 7th of September 1707. He was intended for the law, but became enamoured of natural history, which was the cherished idol of his heart. Unlike Linnæus he had no pecuniary difficulties to struggle with in the commencement of his career, but succeeded at twenty-two years of age to an ample fortune. So far, however, was this circumstance from damping the ardour with which he investigated nature, that it seems to have given a fresh stimulus to his exertions, and he thus affords a bright example to the affluent, who may from him learn that one good purpose which the possession of wealth may serve is the advancement of scientific research. Buffon's unwearied industry has been the theme of general applause, and the fruits of it were several works of interest on his favourite study. The work, however, on which his fame principally rests is that on Natural History. But Buffon, as a philosopher, was not profound, and all his writings are deficient in method. He arranges nothing upon principle; he groups and accumulates, and notes marks of likeness, but he does not distinguish, nor analyze, nor observe the unity of nature. In 1739 he was, by Louis XIV., appointed Intendant of the Royal Garden and Cabinet of Paris, the treasures of which were considerably augmented under his management. He there formed a friendship with Daubenton, to whom he was indebted for much of his anatomical information.

After all, we must admit that as a dis-

coverer Buffon did but little. His chief merit consists in the fascinating garb in which he presented natural history before the public, and thus made its study popular throughout France. The sustained dignity of his style and the brilliancy of his descriptions have been universally admitted. It is unreasonable to expect that a man like Buffon should excel in such opposite qualities as rigid and laborious research, cautious deduction, and flowery eloquence, but as a minister of the temple of nature, he is always instructive and engaging.

But the great defect observable throughout the writings of Buffon, and which certainly should not be concealed, is, that on no occasion does the contemplation of the works of nature call forth from him a religious sentiment, and he consequently has often been accused of indifference to the great First Cause of the sublimities of creation. It is certainly desirable that we at all times remark with delicacy upon the failings of departed genius; but as one great object for which this Society was formed is to point out the hand of the Great Designer in the works of the universe, I feel that I do not transgress the bounds of charity when I say that the works of Buffon would be more in accordance with the spirit of true philosophy if this important omission had been supplied.

After the disappearance of Linnæus and Buffon from the stage they had each of them numerous followers, but their disciples were of a very different character. Those who admired scientific arrangement and profound views of nature studied the works of the great Swedish naturalist; whilst the writings of the French philosopher being more acceptable to the general reader, and being completely in accordance with the character of that nation to which he belonged, there were found many among his own countrymen and throughout Europe, not deeply versed in science, who consulted his splendid compositions.

It would not be consistent with this short sketch to enter into any full account of the numerous contributors to Natural History who adorned the termination of the last century; but there is one great genius that shed a lustre upon England about this time, to whom, as a comparative anatomist whose labours did much to forward the progress of natural history, it would be unpardonable not to allude. The whole life of the celebrated surgeon, John Hunter, was a series of

incessant labour, or rather of delightful occupation, for it was spent in pursuits to which he was devoted heart and soul. The extent and variety of the treasures contained in his famous Museum, and the beautiful dissection and display of each specimen, in reference to its intended object, proclaim the active exertion and industry of this great man, and seem to tell us that there is not one among us who may be disposed to lend his time and zealous exertions to assist in forming the museum which this society is now collecting, to elucidate the several branches of the science we cultivate, however humble may be his talent, who may not signalize himself by adding some interesting object to our collection, and thus by dint of observation and industry contribute to our stock of knowledge.

By the members of the medical profession this appeal should be forcibly felt; to them may belong the honour of forming what I may call a physiological series of comparative anatomy. This series may, in the course of years, become so extensive as to embrace most of the structures, and each subdivision may, as the Hunterian Museum, be arranged in an ascending scale from the most simple to the most complicated, and thus the cultivators of medical science, residing in this town and county, by taking the collections of the immortal Hunter for their guide, may, during the present generation, be the means of collecting together an epitome of general anatomy and physiology. Such a collection will contain the philosophy of life, and by disclosing the grounds on which all the principal divisions of natural history must be founded, will afford the basis of systematic zoology.

In returning from the digression into which I have just been led by the transcendent genius of Hunter, let me endeavour to say a few words explanatory of the progress of natural history in Europe after the death of Linnæus and Buffon, which occurred towards the close of the last century. I may observe that the followers of Buffon may be considered as a dilettanti sect of philosophers, who were pleased to gather the honey from the flowers of science; but the disciples of Linnæus were a more systematic class, and pursued natural history according to more rigorous rules. Too strict an adherence to the letter of the Linnæan system, however, soon became apparent in the writers upon natural history, and this implicit obedience to the authority of

Linnaeus at length rose to such a degree that it became considered a sort of heresy to propose a new division or to name a new genus. The effect of this passive obedience was to stir up in the minds of independent men a distrust of the Linnaean system, and in no branch of natural history has this distrust been carried to a greater length than in botany, and attempts have consequently been made in this country, and more especially in France, to unite the *artificial* arrangements with the *natural* method. This has been termed the *analytic*, and has been exhibited in the "*Flora of France*," published by Lamarck and De Candolle some years back. Long previous to this period Bernard de Jussieu had arranged the plants of the Botanic Garden at Trianon; but the principles that guided him were unknown till his nephew published the basis of his system, under the title of "*Genera Plantarum*," in 1789.

I cannot attempt to do justice to the labours of the numerous naturalists who have adorned this department of science since the Linnaean epoch. From the termination of the last century to the present time has been an era in the history of the world, unparalleled by the degree of intellectual activity which has been displayed, and by the consequent advancement of art and science. After a quarter of a century being distinguished by all the horrors produced by the desolations of war, and after the carnage of millions of human beings had taken place to gratify the ambitious views of a few restless spirits, the nations of Europe seem now to be engaged in the far more glorious rivalry of a zealous prosecution of the branches of useful knowledge and the cultivation of the arts of peace; the result of which is, that a continual interchange of knowledge is going on between the nations of the world, and the scientific investigations of their great men are universally diffused. No branch of knowledge has been more favourably affected by this peaceful repose than natural history. The circumstance of the continent being thrown open to Englishmen has, in this respect, had the happiest effect; for the splendid collections of natural history that are to be found in Paris and in other great capitals of Europe, have been the means of inspiring many a wanderer from this country with a desire to see similar museums spring up in England. Thus a decided taste for this science is propagated abroad, and seems likely to be widely disseminated. But

not only so, the number of books on this subject that have been translated from the French, shows how much we owe to this communication with other countries. There is one extraordinary man, whose prodigious industry and labour have so impressed themselves on the volume of natural history, that he will for ages stand prominently forth as one of the greatest ornaments of this era. The lately departed Cuvier has secured for himself an undying fame, and will be spoken of by succeeding generations as a kindred spirit with Aristotle, and Bacon, and Linnaeus.

Cuvier was born at Montbéliard, in Alsace, in the year 1769, and died in the year 1832. He had comparatively small advantages of education in early life, but showed a decided inclination for the pursuit of zoology—a pursuit into which he seems to have been led by the eloquent descriptions of Buffon.

Circumstances conspired to take Cuvier to Paris, after having, in a secluded situation, devoted himself assiduously to the study of the Mollusca. He there gave lectures which gained him much reputation, and at the establishment of the Institute in 1796, he was chosen one of the original members; and the papers which he read before that body, giving an account of his researches and discoveries in comparative anatomy, enriched their memoirs, and procured for him a high and widely-extended reputation at an early period of life. In 1800 he was appointed Secretary to the Institute. In the same year Buonaparte was appointed President. Cuvier thus, by virtue of his office, was brought into immediate and frequent communication with that extraordinary man, an event which had a material influence upon his future destiny, and opened to him new and wide fields of usefulness and distinction. Such were the powers of his mind, and so great was the versatility of his genius, that in whatever situation he was placed his superiority was soon acknowledged by his associates.

It so happened that the attention of Cuvier had, early in life, been directed precisely to those parts of zoology which the inquiries of preceding zoologists had left the most imperfectly investigated,—the mollusca, vermes, and zoophytes. All these were included in one class by Linnaeus, the class of vermes. This arrangement was materially modified by Cuvier, who based his distinctions of animals principally on their properties of sensation and motion, the most marked

attributes of animals. Observation taught him that certain species of the mollusca, which had been indiscriminately denominated white-blooded, had red blood and a circulating system; he collected them into a distinct class, the Annelides; still correctly included, in conformity to his general view, among the invertebrated animals, although previously both incorrectly classified and designated. The best proof of the correctness of the principle of Cuvier's classification is, that in the progress of his observations it became confirmed by a wider application, and the principle of the masterly arrangement of his great work on the animal kingdom. Thus examining the modifications of the organs of the circulation, respiration, and sensation throughout the animal kingdom; instead of the six classes of Linneus, namely, quadrupeds, birds, reptiles, fishes, insects, and worms, M. Cuvier established four great types,—vertebrated animals, molluscous animals, articulated animals, and radiated animals, which he calls *embranchemens*, and divides these into classes of nearly equal value with those long established among the vertebrated animals.

(To be Continued.)

THE ANATOMIST.

MUSCLES.

Palmaris longus. O. inner condyle and fascia of forearm. I. Annular ligament and palmar aponeurosis, near root of thumb.

Flexor carpi ulnaris. O. inner condyle, inner side of olecranon, inner edge of nearly whole length of ulna, and forearm. I. os pisiforme and base of fifth metacarpal bone.

Flexor digitorum sublimis perforatus. O. inner condyle, internal lateral ligament, coronoid process, and radius below tubercle. I. anterior part of second phalanges of each finger.

Flexor digitorum profundus perforans. O. three upper fourths of anterior surface of ulna, internal half of interosseous ligament, sometimes from radius below its tubercle. I. last phalanx of each finger.

Flexor pollicis longus. O. fore part of radius below the tubercle, and from interosseous membrane to within two inches of carpus, sometimes from coronoid process. I. last phalanx of thumb.

Pronator quadratus. O. inferior fifth of anterior surface of ulna. I. anterior part of inferior fourth of radius.

Supinator radii longus. O. external ridge of humerus to within two inches of outer condyle, and from intermuscular ligament. I. rough surface on the outside of radius, near its styloid process.

Extensor carpi radialis longior. O. ridge of humerus, between supinator longus and external condyle. I. back part of carpal extremity of metacarpal bone of index finger.

Extensor carpi radialis brevior. O. inferior and posterior part of external condyle, and external lateral ligament. I. carpal extremity of third metacarpal bone.

Extensor digitorum communis. O. external condyle, fascia of forearm and its intermuscular septa, and from ulna. I. posterior aspect of all the phalanges of four fingers.

Extensor carpi ulnaris. O. external condyle, fascia, and septa, and from ulna. I. carpal end of fifth metacarpal bone.

Anonæus. O. posterior and inferior part of external condyle and lateral ligament. I. external surface of olecranon, and superior fifth of posterior surface of ulna.

Extensor minimi digiti. O. in common with and between extensor digitorum communis and extensor carpi ulnaris. I. posterior part of phalanges of little finger.

Supinator radii brevis. O. external condyle, external lateral, and coronary ligaments, and from a ridge on outer side of ulna, which commences below its lesser sigmoid cavity. I. upper third of external and anterior surface of radius, from above its tubercle to the insertion of pronator radii teres.

Extensor ossis metacarpi pollicis. O. middle of posterior part of ulna, below the anconeus, interosseous ligament, and posterior surface of radius. I. os trapezium and upper and back part of metacarpal bone of thumb.

Extensor primi internodii pollicis. O. back part of ulna, below its middle, interosseous ligament, and radius. I. posterior part of first phalanx, and often the second.

Extensor secundi internodii pollicis. O. posterior surface of ulna, above its centre, and from interosseous ligament. I. posterior part of last phalanx.

Extensor indicis. O. middle of posterior surface of ulna, and interosseous ligament. I. second and third phalanges.

Abductor pollicis. O. anterior aspect of annular ligament, os naviculare, and trapezium. I. outside of base of first phalanx, and by an expansion into both phalanges.

Opponens pollicis. O. annular ligament and os naviculare. I. anterior extremity of metacarpal bone of thumb.

Flexor pollicis brevis. O. external head, from inside of annular ligament and trapezium and scaphoid bones. I. external sesamoid bone and base of first phalanx of thumb. *Internal head.* O. from os magnum and base of metacarpal bone of middle finger. I. internal sesamoid bone and base of first phalanx.

Adductor pollicis. O. three-fourths of anterior surface of the third metacarpal bone. I. inner side of root of first phalanx of thumb.

Abductor indicis. O. metacarpal bone of fore finger and one-half of that of thumb. I. outer side of base of first phalanx.

Lumbricales. O. outer side of the tendons of flexor profundus, near the carpus, a little beyond annular ligament. I. middle of first phalanx into tendinous expansion covering the back of each finger.

Abductor minimi digiti. O. annular ligament and os pisiforme. I. ulnar side of first phalanx.

Flexor brevis minimi digiti. O. annular ligament and unciform bone. I. base of first phalanx of little finger.

Adductor minimi digiti. O. internal to last, and overlapped by it. I. all the metacarpal bone of little finger.

Interossei antici, vel interni, vel palmares. O. sides of metacarpal bones. I. first phalanges and tendinous expansion, covering the dorsum of each finger.

1st, *vel prior, vel externus indicis.* O. radial side of second metacarpal bone. I. external side of first phalanx of fore finger.

2nd, *vel posterior, vel internus, vel adductor indicis.* O. ulnar side of second metacarpal bone. I. inner side of first phalanx of ring finger.

3d, *vel prior, vel externus, vel adductor annularis.* O. radial side of fourth metacarpal bone. I. external side of first phalanx of fore finger.

4th, *vel abductor minimi digiti.* O. radial side of fifth metacarpal bone. I. outside of first phalanx of little finger.

Interossei posteriores. O. opposed sides of two metacarpal bones. I. base of first phalanx of each finger and posterior tendinous expansion.

1st, *prior vel externus medii.* O. second and third metacarpal bones. I. outer side of base of first phalanx of middle finger.

2nd, *vel internus medii.* O. between the metacarpal bones of middle and ring fingers. I. inner side of first phalanx of middle finger.

3rd, *vel externus annularis.* O. between fourth and fifth metacarpal bones. I. inner side of ring finger.

ABDOMEN.

Obliquus externus vel descendens. O. external surfaces of eight or nine inferior ribs at a little distance from their cartilages. I. ensiform cartilage, linea alba, os pubis, Poupart's ligament, anterior superior spinous process of ilium, and outer edge of two anterior thirds of crista ilii.

Obliquus internus vel ascendens. O. fascia lumborum, all the crista ilii, and external third or fourth of Poupart's ligament. I. cartilages of seven inferior ribs, ensiform cartilage, linea alba, also by conjoined tendons into symphysis and upper edge of pubis, and into linea ileopectinea.

Cremaster. This muscle, deriving part of its origin from internal oblique, is here described, though being a muscle of the testicle. O. inner surface of external third of Poupart's ligament, and from lower edge of obliquus internus, and sometimes from transversalis; it often has an attachment to the pubis. I. tunica vaginalis and scrotum.

Transversalis. O. fascia lumborum, posterior part of crista ilii, iliac third of Poupart's ligament, and inner side of seven inferior ribs. I. along with posterior lamina of obliquus internus, into the whole length of linea alba, upper edge of pubis and the linea innominata.

Rectus. O. upper and anterior part of pubis. I. ensiform cartilage, costoxiphoid ligament, and cartilages of sixth and seventh ribs.

Pyramidalis. O. broad from pubis. I. linea alba, mid-way to umbilicus; sometimes wanting.

DEEP MUSCLES OF THE ABDOMEN.

Diaphragm is divided into two portions; a superior broad or true diaphragm; and an inferior lesser portion, or crura diaphragm.

True diaphragm. O. posterior surface of xiphoid cartilage, internal surfaces of cartilages of the last true and all the

false ribs, external or false ligament arcuatum, and convex edge of true ligamentum arcuatum. *I.* cordiform tendon.

False or lesser diaphragm, or crura. *O.* right crus, from fore part of bodies of four superior lumbar vertebræ. Left crus from the sides of the two or three superior lumbar vertebræ. *I.* posterior border of cordiform tendon.

Quadratus lumborum. *O.* posterior fourth of spine of ilium, and from ilio-lumbar ligament. *I.* extremity of transverse processes of four superior lumbar and last dorsal vertebræ, also inner surface of posterior half of last rib.

Psoas parvus. *O.* side of last dorsal and first lumbar vertebræ. *I.* linea ileo-pectinea, fascia iliaca, and fascia lata, behind the femoral vessels; sometimes wanting.

Psoas magnus. *O.* sides of bodies of two last dorsal, and from bodies and transverse processes of all the lumbar vertebræ, also from inter-vertebral ligaments. *I.* inferior part of lesser trochanter and ridge below that process.

Iliacus internus. *O.* transverse process of last lumbar vertebra, inner margin of three anterior fourths of crista ilii, and its two anterior spinous processes and intervening notch, brim of acetabulum, capsular ligament, iliac fossa, and iliac fascia. *I.* into psoas magnus; the inferior fibres are inserted into anterior and inner surface of femur, below trochanter minor.

MUSCLES OF MALE PERINÆUM.

Sphincter ani. *O.* ano-coccygeal ligament. *I.* into raphe, superficial fascia, and common central point of perinæum.

Sphincter internus encircles the lower part of rectum.

Erector penis. *O.* inner surface of tuber ischii, and from insertion of great or inferior sciatic ligament. *I.* fibrous membrane of crus penis.

Accelerator urinæ. *O.* 1st, triangular ligament of the urethra; 2nd, by a broad tendon common to opposite muscles, which lies above urethra, between it and pubis; 3rd, by a tendinous expansion from the side of crus penis. *I.* middle tendinous line or raphe of perinæum.

Transversalis perinæi. *O.* inside of tuber ischii. *I.* central point of perinæum.

Levator ani. *O.* posterior part of symphysis pubis, obturator fascia, ilium above thyroid foramen, inner surface of ischium, and its spinous process. *I.* anterior fibres into central point of peri-

næum and fore part of rectum; middle fibres into side of rectum, posterior fibres into back part of rectum, os coccygis, and last bones of sacrum.

Compressor urethræ. *O.* by a tendon from the inside of symphysis pubis. *I.* below membranous portion of urethra, into the narrow tendinous line, which becomes lost in central point of perinæum.

Coccygeus. *O.* inner surface of spine of ischium. *I.* extremity of sacrum and side of coccyx.

MUSCLES OF FEMALE PERINÆUM.

Sphincter ani. *O.* ano-coccygeal ligament. *I.* raphe, superficial fascia, and common central point of perinæum.

Levator ani. *O.* posterior part of symphysis pubis, below true ligaments of bladder, obturator fascia, ilium above thyroid foramen, inner surface, and spine of ischium. *I.* the same as in the male.

Coccygeus, as in the male.

Transversalis perinæi, as in the male.

Erector clitoridis. *O.* inner surface of tuber ischii, and insertion of great sciatic ligament. *I.* fibrous membrane of crus clitoridis.

Sphincter vaginæ, extends from clitoris superiorly, around each side of vagina to central point of perinæum, in front of anus.

MUSCLES OF THE INFERIOR EXTREMITY.

Fore Part and Sides of the Thigh.

Tensor vaginæ femoris. *O.* external part of anterior superior spine of ilium. *I.* fascia lata about three inches below the great trochanter.

Sartorius. *O.* anterior superior spine of ilium and notch beneath it. *I.* inner side of upper end of tibia, below its tubercle.

Rectus femoris. *O.* anterior inferior spinous process of ilium, acetabulum, capsular ligament. *I.* upper edge of patella.

Vastus externus. *O.* root and anterior part of great trochanter, outer edge of linea aspera, oblique ridge leading to external condyle, all internal surface of femur, and fascia lata. *I.* external surface of tendon of rectus, side of patella, and head of tibia.

Vastus internus. *O.* anterior part of femur, linea inter-trochanterica, inner edge of linea aspera, and inside of femur. *I.* inner edge of tendon of rectus, patella, and head of tibia.

Cruræus. *O.* anterior and external

part of femur, commencing at linea intertrochanterica, and extending along three-fourth of the bone, as far outwards as linea aspera. *I.* upper and outer edge of patella, and synovial membrane of knee joint.

Subcrureus or *capsularis*. *O.* inferior fourth of anterior surface of femur. *I.* synovial membrane of knee joint.

Gracilis. *O.* lower half of symphysis, and inner edge of descending ramus of os pubis. *I.* superior part of internal surface of tibia.

Pectineus. *O.* linea innominata on horizontal ramus of pubis. *I.* rough ridge leading from lesser trochanter to linea aspera.

Triceps adductor femoris.

1st, *adductor longus*. *O.* anterior surface of pubis, between spine, and symphysis. *I.* middle third of linea aspera.

2nd, *adductor brevis*. *O.* anterior inferior surface of pubis, between symphysis and thyroid foramen. *I.* superior third of internal root of linea aspera to three inches below lesser trochanter.

3d, *adductor magnus*. *O.* anterior surface of descending ramus of pubis, ramus of ischium, and external border of its tuberosity. *I.* rough ridge leading from great trochanter to linea aspera, linea aspera, and internal condyle of femur.

MUSCLES OF HIP.

Glutæus maximus. *O.* posterior fifth of crista ilii, the rough surface between it, and superior semicircular ridge, posterior ilio-sacral ligaments, lumbar fascia, spines of sacrum, side of coccyx, and great sciatic ligament. *I.* rough ridge leading from great trochanter to linea aspera, upper third of linea aspera, and fascia lata.

Glutæus medius. *O.* deep surface of fascia covering it, three anterior fourths of crista ilii, superior semicircular ridge, and surface of ilium above and below it. *I.* upper and outer part of great trochanter.

Glutæi minimus. *O.* inferior semicircular ridge on dorsum of ilium, rough surface between it, and edge of acetabulum. *I.* upper and anterior part of great trochanter.

Pyriformis. *O.* concave aspect of 2nd, 3rd, and 4th divisions of sacrum, upper and back part of ilium, and anterior surface of great sciatic ligament. *I.* upper part of digital fossa.

Gemellus superior. *O.* spine of ischium. *I.* upper part of digital fossa.

Gemellus inferior. *O.* upper part of tuber ischii, and great sciatic ligament. *I.* digital fossa.

Obturator internus. *O.* pelvic surface of obturator ligament, circumference of obturator foramen, and obturator fascia. *I.* digital fossa.

Quadratus femoris. *O.* external surface of tuber ischii. *I.* Inferior and posterior part of great trochanter and posterior inter-trochanteric line.

Obturator externus. *O.* inferior surface of obturator ligament and surrounding surfaces of pubis and ischium. *I.* digital fossa.

MUSCLES ON BACK PART OF THIGH.

Biceps flexor cruris. *Long head*. *O.* outer and back part of tuber ischii. *Short head*. *O.* linea aspera, from below insertion of glutæus maximus to within two inches of external condyle. *I.* head of fibula.

Semitendinosus. *O.* tuberosity of ischium, and from three inches of the tendon, long head of biceps. *I.* anterior angle of tibia, below tubercle.

Semimembranosus. *O.* upper and outer part of tuber ischii. *I.* external condyle of femur, forming the ligament of Winslow, posterior heads of tibia and fibula, and head of tibia.

MUSCLES ON ANTERIOR AND EXTERNAL PART OF LEG.

Tibialis anticus. *O.* outer part of two superior thirds of tibia head of fibula, inner half of interosseous ligament, fascia of leg, and intermuscular septa, *I.* inner side of internal cuneiform bone and base of first metatarsal bone.

Extensor digitorum longus. *O.* external part of head of tibia, head and three-fourths of fibula, part of interosseous ligament, fascia of leg, and intermuscular septa. *I.* last phalanges of four external toes.

Extensor pollicis proprius. *O.* inner edge of middle third of fibula, interosseous ligament, and lower part of tibia. *I.* bases of first and second phalanges of great toe.

Peronæus tertius. *O.* anterior surface of lower half of fibula. *I.* base of fifth metatarsal bone.

Extensor digitorum brevis. *O.* upper and anterior part of os calcis, cuboid bone, astragalus and annular ligament. *I.* internal tendon into base of first phalanx of great toe, the three others join the outer edges of corresponding tendons of extensor digitorum longus.

MUSCLES ON OUTER PART OF LEG.

Peroneus longus. O. around head of fibula, adjacent surface of tibia, upper half of external angle of fibula, fascia and intermuscular septa. I. outer side of metatarsal bone of great toe, adjacent sesamoid bone, internal cuneiform bone and base of second metatarsal bone.

Peroneus brevis. O. outer and back part of lower half of fibula, and intermuscular septa. I. on cuboides and base of metatarsal bone of little toe.

WORKING OF THE NEW POOR LAW ACT.

Southwark, May 24, 1837.

SIR,—The Council of the British Medical Association consider that the publication of the enclosed copies of a correspondence between Dr. Webster, our President, and Mr. Chadwick may be useful and interesting to the profession at the present moment. they have therefore instructed me to transmit them to you, with a request that you will please to insert them in your Journal.

I am, Sir, your obedient servant,
Wm. EALES, Hon. Sec.
To M. Ryan, Esq., M.D.

Dulwich, 21st April, 1837.

SIR,—As the President of a large Medical Association, and referring to the conversation I had the honor of holding with you on Saturday last, I desire respectfully to submit the following queries through you, to the consideration of the Board of Commissioners.

1st.—If medical gentlemen be proposed or appointed, as parochial attendants, by a Board of Guardians, and their appointments confirmed by the Poor Law Commissioners, is it considered that such gentlemen hold their situations of the Guardians or the Commissioners?

2nd.—Can parish surgeons, so appointed, be suspended or removed without the approval of the Commissioners?

3rd.—Are such appointments considered to be during good behaviour? Are they annual appointments as under the old law? Or can they be terminated at the pleasure of the Guardians, without any particular reason, such as inattention, misconduct, &c.?

4th.—Would the Poor Law Com-

missioners sanction any Board of Guardians in passing certain resolutions (to be made known to five only out of thirty medical gentlemen, in the parish or union) making it a *sine qua non* that the candidates for the office of parish surgeon should belong to any medical club that might be formed in such parish?

5th.—Has the Board of Guardians any power to fix the qualifications of parish surgeons, in so far, that the candidates must be members of the College of Surgeons, and also licentiates of the Apothecaries' Company? Is not this exceeding the limits of the Act of Parliament?

6th.—Are members of the Scotch and Irish Colleges equally eligible with members of the London Colleges to the office of medical attendant to the poor?

Answers to the above queries would be gratifying to the Committee of the British Medical Association, now sitting to consider the effects of the present plan for administering medical relief to the sick poor.

I beg to forward the pamphlets which I mentioned to you as, in my humble opinion, worthy the consideration of yourself and the Commissioners,

I am, Sir,
your most obedient servant,
(Signed) GEO. WEBSTER, M.D.
To Edwin Chadwick, Esq.,
Secretary to the Poor Law Commissioners.

Poor Law Commission Office,
Somerset House, 18th May, 1837,

SIR,—Your letter of the 21st ultimo has been brought under the consideration of the Poor Law Commissioners for England and Wales, who, in reply to your several inquiries, desire to state.—

1st.—That the terms of a medical officer's appointment are prescribed by his contract; he is subject to the Guardians' immediate orders under the rules of the Commissioners, and is only liable to be dismissed by the Commissioners, under the 48th section of the Poor Law Amendment Act.

2nd.—A medical officer can be suspended or removed only for gross misconduct, or such neglect of his contract as would disentitle him to the benefit of its provisions.

3rd.—The appointments of medical officers are annual.

4th.—The Commissioners could not sanction the passing of any resolution by the Guardians, to the effect described in your fourth inquiry. The only qualifi-

cation for medical officers which the Commissioners can allow, are:—

1. The being authorized by law to practice.

2. That the person has not rendered himself objectionable, by forfeiting character for skill or propriety of conduct.

5th.—It is competent to the Guardians to appoint any qualified person as medical officer; but it would not be illegal, if they, with their present discretion, should insist upon a concentration of legal qualifications, such as are instanced in the inquiry.

6th.—The office of medical attendant is not simply that of an Apothecary, the Commissioners, therefore, do not consider that members of the Scotch and Irish Colleges are excluded.

Signed, by order of the Board,
E. CHADWICK, Secretary.

METROPOLITAN FREE HOSPITAL,

29, Carey-street, Lincoln's Inn Fields,

Established in June, 1836, for the Gratuitous Relief of the Sick Poor of every Nation and Class, without Letter or other Introduction.

REPORT OF THE COMMITTEE, &c., 1837.

THE Committee of the METROPOLITAN FREE HOSPITAL, in presenting this their first annual Address, beg leave to congratulate the Vice-Presidents and Governors on the increasing prosperity of this Institution, which has, in a period of eleven months, enabled them to alleviate the sufferings of 3,928 of their fellow-creatures.

This Institution requires no letter of introduction or recommendation to afford the objects of its bounty immediate and efficient aid in sickness and disease,—a circumstance it should be remembered not general in the Hospitals of this Metropolis; indeed, it stands almost or quite alone in that particular, benefitting immensely by such plan its suffering applicants, as must be obvious to all, even without the strong confirmation of the great increase of its patients, as exhibited in the Medical Officers' Report. Letters of recommendation are at times procured with difficulty, too frequently unattainable, and more especially by the forlorn and destitute stranger, who, unknown and unpitied, often seeks in vain for a letter

of admission; and if success attends a wearied and exhausted supplicant, it is often after a dangerous and fatal delay; but here disease and destitution are the only requisite credentials for the afflicted poor to find relief,—who may with grateful hearts truly exclaim with the holy Psalmist, “Blessed be the man that provides for the sick and needy.”

To the Medical Report the Committee refer with the utmost confidence, proving, as it clearly does, the extensive operations of this Charity, during a season of unusual severity, accompanied by an epidemic of unexampled prevalence.

The demands upon a charity so extensive and unlimited must necessarily be great, the generous sympathy, however, of its subscribers has hitherto supplied them.

The financial affairs are subjected to the most searching inquiry, with the view of using the donations with strict economy, and advancing to the utmost your benevolent intentions most ably seconded as they are by the gratuitous aid of the officers.

The Committee, however, notwithstanding the pleasure they find in the relief afforded to the great number of persons stated, 184 of which were surgical accidents, and 54 cases of disease of the eye, feel themselves most anxious to extend the field of generous labour, by providing a building, which will enable them to receive within wards, such patients whose cases demand constant indoor attendance, or where severe surgical operations are required. Strongly impressed with so great and necessary an advantage, the committee have already commenced a subscription, met, as they think, by a willingness and spirit, cheering the hope of triumphant success; they earnestly appeal, therefore, to the nobility and public in general, to furnish them with supplies, the only means of more largely ameliorating the sufferings of the poor: and take into their serious consideration how greatly such object will be advanced by their giving cordial assistance and support to the “Building Fund of the Metropolitan Free Hospital.

REPORT OF THE MEDICAL COMMITTEE.

Eleven months have elapsed since the Metropolitan Free Hospital was first opened to the public, and the medical officers experience no small degree of gratification in reverting to their proceedings during that period.

Situated in the midst of a thickly inhabited district, abounding in poor, whose means of subsistence are scanty and uncertain, and amongst whom disease might well be expected to keep pace with destitution, the medical officers of the Metropolitan Free Hospital have found ample opportunity, and no lack of applicants, upon whom to exercise the charity that has been supplied by the generosity and benevolence of a liberal body of governors.

In the first eleven months of their duty they have relieved no fewer than 3,928 poor persons, giving an average of 4,285 upon the year ending on the 14th of May, 1837; the medical officers feel some degree of confidence in the consciousness that their exertions have in a great majority of instances availed in restoring to perfect health these unfortunate applicants.

During the long and inclement winter now scarcely passed, the distress of the poor was greatly increased by an epidemic of unusual severity; it attacked all indiscriminately,—the strong and robust men not less than the delicate female or the tender and helpless infant. At this time the Metropolitan Free Hospital was of incalculable advantage to the poor in its vicinity; and the medical officers have no hesitation in believing that, by its means, many a parent has been saved to his destitute and unprovided family.

They believe that the success which this Institution has achieved is without precedent in the history of medical charities of the Metropolis. The numbers relieved in its first year of its existence, and the extremely moderate cost at which it has been done, furnish matter of congratulation to those who have been the almoners of the charitable governors, and at the same time encourages the latter not to relax in their contributions for the same useful purposes.

There has been an election for Apothecary to the hospital, in place of Mr. Hentsch who had resigned. While the medical officers express their approbation of the manner in which Mr. H. performed his duties, they believe that they have reason to congratulate the governors in the appointment of an efficient successor in the person of Mr. Jones.

The apothecary's department has necessarily participated in the general expenditure attendant upon a first outlay; but they are instituting an arrangement in it, by which they hope that the expense will be further materially diminished, without in any way inter-

fering with the general efficiency of the establishment.

The medical officers report with pleasure the establishment of an ophthalmic department in this hospital, by which the poor, afflicted with diseases of the eye, may find immediate relief on application at those hours set apart for this purpose.

The medical officers cannot close their report without recording their unanimous acknowledgments of the courteous manner and cordial desire of co-operation which has ever characterized the conduct of the committee of management towards them. It augurs well for the prosperity of the hospital, that men so zealous should have had the controul of its affairs, and they congratulate themselves in having been associated with gentlemen so fully entitled to their confidence and respect.

METROPOLITAN FREE HOSPITAL.

GENERAL REGISTER.

We, the undersigned President of the Royal College of Physicians, President of the Royal College of Surgeons, and Master of the Worshipful Society of Apothecaries, having authority from the several bodies whom we represent, do resolve to fulfil the intentions of the Legis-

lature in procuring a better registration of the causes of death, being convinced that such an improved registration cannot fail to lead to a more accurate statistical account of the prevalence of particular diseases from time to time.

We pledge ourselves, therefore, to give in every instance which may fall under our care, an authentic name of the fatal disease.

And we entreat all authorized practitioners throughout the country to follow our example, and adopt the same practice, and so assist in establishing a better registration in future throughout England; for which purpose we invite them to attend to the subjoined explanatory statement, in which they will set forth the provisions of the recent statute, and the means whereby the important object we have recommended may most effectually be attained.

HENRY HALFORD,
President of the Royal Col. of Physicians.

ASTLEY COOPER,
President of the Royal Col. of Surgeons.

J. HINGESTAN,
Master of the Society of Apothecaries.

EXPLANATORY STATEMENT.

The recent Act for registering births, deaths, and marriages in England, presents an opportunity for obtaining that great desideratum in medical statistics—a more exact statement of the causes of death, in the case of every registered death throughout the whole of England and Wales, after the month of June next ensuing.

The register-books in which all deaths are to be registered after the last day of June, 1837, contain columns wherein may be inserted the cause of death in juxtaposition with those other important illustrative circumstances, the sex, the age, and the profession or calling of the deceased person. Each register-book will also be assigned to a particular district of small extent, and will thus show in what part of the kingdom each death has occurred. If, therefore, the cause of death be correctly inserted, there will exist thenceforward public documents, from whence may be derived a more accurate knowledge, not only of the comparative prevalence of various mortal diseases, as regards the whole of England and Wales, but also of the localities in which they respectively prevail, and the sex, age, and

condition of life which each principally affects.

For the attainment of this object it is necessary to ensure, as far as possible, the “cause of death.” It is obvious that on this subject the requisite information can seldom be given to the registrar, except by the medical attendant on the deceased person, and that even if the registrar be a medical practitioner (which in many instances will be the case), yet will he often be unable to ascertain the truth in this respect, if he is to depend solely on the reports of persons ignorant of medicine, and of the names and nature of diseases; and it cannot be expected that from his own knowledge he will be able so far to correct their errors as to ensure a statement worthy of credit. The requisite information must therefore be supplied, either directly or indirectly, by the medical attendant of the deceased person; that is to say, if such medical attendant is not applied to by the registrar, he must afford the requisite information to those other persons to whom the registrar must apply.

The persons who, according to the act for registering births, deaths, and marriages in England, must give information to the registrar on being requested so to do, are “some person present at the death, or in attendance during the last illness,” or “in case of the death, illness, inability, or default of all such persons, the occupier of the house or tenement, or, if the occupier be the person who shall have died, some inmate of the house or tenement in which such death shall have happened.” It is also provided that “for the purposes of this act the master or keeper of every gaol, prison, or house of correction, or workhouse, hospital, or lunatic asylum, or public or charitable institution, shall be deemed the occupier thereof.”

It is therefore earnestly recommended that every practising member of any branch of the medical profession who may have been present at the death, or in attendance during the last illness, of any person, shall immediately after such death place in the hands of such other persons as were in attendance, of the occupier of the house in which the death occurred, and of some inmate who may probably be required to give information, written statements of the cause of death, which such persons may show to the registrar, and give as their information on that subject.

It is desirable that such statement

should be very short, the column in the register-book in which it is to be inserted being not more than sufficient for the insertion of about ten words of moderate length. It should, therefore contain only the name of the disease which was considered to be the cause of death, and not a detailed account either of antecedent symptoms, or of the appearances which may have presented themselves after death. It is also desirable that such statement should exhibit the popular or common name of the disease, in preference to such as is known only to medical men, whenever the popular name will denote the cause of death with sufficient precision.

CASE OF STRANGULATED CRURAL HERNIA.

Occurring in a Pregnant Female, in which an Operation was successfully performed.

BY JOHN PAUL, M.D.,
Surgeon to Gray's Hospital, Elgin,

Mrs. Ritchie, æt. 35, the mother of five children, was seized with symptoms of strangulation in an irreducible crural hernia of the right side, on August 30, 1836. The protrusion, she said, had taken place about two years and a half before during severe vomitings, which she had in the incipient stage of a former pregnancy; and since that time she has never been free from pain in her back, which has always given her a feeling of something dragging down there. The bowels too became so torpid in their peristaltic motion, that they never acted without drastic purgatives, and then only with very great uneasiness. The tumour was tense, somewhat tender, and larger than what a crural hernia generally is; vomiting was most distressing and almost incessant; the bowels were completely obstructed—Mrs R. considered herself three months advanced in pregnancy.

It was thought useless to make any very great effort at reduction by the taxis, as the hernia had never been reduced from the time it first protruded. Powerful enemata were administered in the first instance, by introducing a tube into the bowel as far as possible, but without any effect in relieving the obstruction. The patient was then bled and put into a warm bath, with no better result. On the following day the symptoms of strangula-

tion were more urgent, stercoraceous vomiting was almost incessant, the tumour was very tense and painful, and the pulse getting very rapid. I urged the necessity of an immediate operation, which was agreed to. On opening the sac I found it contained a large knucle of intestine and a portion of omentum twisted into the form of a cord, without a particle of adipose matter; there was considerable adhesion between the intestine and sac which I separated with my finger. The stricture being divided the bowel was returned with greater ease, the edges of the wound were kept together by stitches, and a compress and bandage applied; a glyster was in less than an hour administered which procured a large liquid stool, this was followed up in the course of a few hours by small doses of Epsom salts, which operated freely; and for a time alvine discharges were daily elicited by some mild aperient. On removing the stitches on the fifth day I observed the portion of corded omentum again in the sac, in a sloughy condition; in the course of eight or ten days it was removed, and then the wound granulated kindly. On the 6th of March my patient was delivered of a full grown female child, and is now in the enjoyment of excellent health.

I have been induced to put this case on record, because I am not aware that an operation has been performed for the reduction of strangulated hernia in a pregnant female; but whether the case is unique or not it cannot fail to be interesting, inasmuch as it is additional proof, if not the first case to establish the fact, that strangulated hernia may be relieved in pregnancy by operation without its inducing abortion. When every other means of reduction have failed, pregnancy must not be considered an objection to operating; uterine contraction supervening, no doubt materially adds to the danger which always exists under ordinary circumstances; but this, great as it may be, will bear no comparison to that danger to which the patient is inevitably exposed if left without this last resource of surgery.

Elgin, May 20, 1837.

[This case reflects very great credit on Dr. Paul, as there are few surgeons who would venture to operate under similar circumstances, though the patient would have most probably died, without an operation. There are few, if any, cases of this description on record, which shows the judicious boldness and solid judgment of the operator.]—Eds.

THE KING'S HEALTH.

(From our Windsor Correspondent.)

No sooner had the nation been gladdened by the intelligence of a temporary improvement in Her Majesty's health, than they received the announcement of serious indisposition of the King. Those who were in the habit of visiting Windsor, had, for some time past, been struck with a perceptible change in the general appearance of His Majesty; and though his condition was anxiously watched by Mr. Davis, Surgeon to the household, it was not until the evening of Sunday, the 21st of May, that the Royal Family became so alarmed as to deem it expedient no longer to delay procuring the able assistance of the distinguished President of the Royal College of Physicians. Accordingly, an express was sent, commanding Sir Henry's immediate attendance, and the worthy Baronet arrived at full speed soon after ten o'clock within the gates of the castle; and though considerable alarm was excited by his meteor-like appearance, yet the loyal feelings of the people of Windsor were highly gratified in the Royal patient being placed under the skilful and judicious vigilance of a physician so thoroughly and inimitably acquainted with the constitution and habits of the Royal Family, as well as in one in whom the Sovereign, and all the branches of the Royal Family, as well as the nobility and gentry of England, have long placed a most unbounded confidence. Though the medical attendants of the Royal Household are necessarily bound not to divulge the secrets of the Royal bed-chamber, the intense interest which prevailed throughout all classes, led many circumstances to transpire touching the health of His Majesty, which in moments of less anxiety would never have been matters of conversation. Indeed, from the commencement, His Majesty has expressed a particular desire that his ailment should not become a matter of conversation, far less that any individual of the Household should make any communications in writing on the subject; and it is in accordance with these feelings of His Majesty that no bulletins have been issued, documents which, from the pen of Sir Henry, though they would have given high satisfaction to those who are interested in the particulars of His Majesty's complaint, yet might have created so much public anxiety, as to have been prejudicial to the interests of the State.

The great embarrassment in His Majesty's breathing, and profuse mucous expectoration, along with the symptoms of extreme debility with which they were accompanied, were a just cause of alarm during several of the first days of Sir Henry's attendance. By the judicious administration of medicine, a very remarkable mitigation of the more severe symptoms of His Majesty's disease, was effected; though I deeply regret to state that other symptoms have been super-added, which though not of so severe a nature, are still far from being of a favourable character,—I allude to the swellings of the extremities, the precise degree of which I have not been as yet able to ascertain, as all those visitors by whom the King has been seen, particularly mention that the dress of His Majesty is so contrived as completely to veil his external appearance. The royal mind, I rejoice to state, continues to possess its wonted vigor and activity, so that the King has not only given audiences to the great officers of state, but has continued to give his personal commands to the various individuals of His Majesty's Household.

REVIEW.

De la Generation. Par Ch. Girou de Buzareingues, Correspondent de l'Academie Royale de Science, &c. &c.

On Generation. By Ch. Girou de Buzareingues, Corresponding Member of the Royal Academy of Sciences, &c. &c. 8vo. pp. 340.

The author of this work confines his conclusions to the inferior order of mammiferæ, and especially to those animals which are under the observation of agriculturists. He commences by noticing the principal systems of generation, comments upon them, and offers general considerations on the influence of the fathers and mothers in relation to the resemblance and sex of the offspring. He next proceeds to notice the results of his observations on the reproduction of the conformation and sexes, and the general influence of parents on the external and internal characters. After a careful comparison of the facts stated in this work, with those we have already published in this Journal, we are constrained to admit, that we find nothing new, or what has not been already described by preceding writers. He is also silent on human generation, with the exception of a very brief account of the theories of the physiologists.

NOTES OF LECTURES ON PHYSIOLOGY.

BY DR. FLETCHER.

*Delivered in the Argyle Square School of
Medicine, Edinburgh.*

No. XXVI.

ETIOLOGY.

Exciting Causes of Disease—Poisons—
Arsenic—Mode in which it Destroys
Life—Different Effects of Large, Small,
and Moderate Doses—Analogy with Cho-
lera—Character of the pain produced by
it—Experiment on a Dog—Corrosive
Sublimate—Hydrophobia—Manner in
which the Virus acts—Tabular view of
Poisons—Diseases and the principal Poi-
sons which produce them—Organic Dis-
eases—Functional Diseases—Poisons
and the principal Diseases which they
produce—Animal Poisons—Vegetable
Poisons—Mineral Poisons—Tests for
Poisons—Sympathy—Diseases which
have been attributed to it—Critical Dis-
charges—Opinions of Hippocrates, De
Haen, Hoffman, Scudamore, Abernethy,
Alibert, Bateman, Broussais, and Mar-
shall Hall—Wounds—Mode in which
they produce Tetanus—Venoms and Vi-
ruses—Cause of their Fatal Effects—
Indian Serpents and other Venomous
Animals—Effects of the Bite of the
Tarantula—List of the Principal Viruses
—Wounds in Dissection—Cause of their
Dangerous Effects—Poison from Gan-
grene—Alleged Vitiating of the Blood—
Arguments against it—Innoculation by
the Blood—Congenital Syphilis—Syphi-
lis Communicated by Suckling—Hydro-
phobia from Fright—Various Theories
on the Difference between Innoculated
and Natural Small-pox—Manner in
which Cow-Pock secures from Small-Pox
—Poison of the Viper—Suppressed Se-
cretions—Explanation of their Injurious

No. 10.

Effects—Diseases produced by suppressed
Perspiration, Nasal Mucus, Menses, and
Lochia—Effects of Snuff Taking—Re-
tained Secretions—Diseases produced
by Retained Bile, Feces, Urine, and
Milk—Secondary Effects of Retained
Secretions—Exercise—Diseases pro-
duced by the Abuse and by the Neglect
of Exercise—Effects of want of Exer-
cise on Animals—Stalled Oxen and Fat-
ted Geese—Sleep—Analogous Effects
to those of Food and want of Exercise—
Diseases produced by too much Sleep—
Diseases produced by too little Sleep.

Arsenic kills by paralyzing the brain,
the heart and the stomach; it acts on the
nervous system and not by inflammation.
Its effects are too quick to be attributed
to the latter. In a small dose it produces
tetanus, in a larger, not tetanus but in-
flammation, but in a still larger dose, it
kills at once without either; in this re-
spect it resembles cholera. The part of
the intestinal canal which, after the sto-
mach, is most affected by the inflamma-
tion produced by arsenic, is the lower
part of the rectum; and this is the case
at whatever part of the system the poison
may be introduced. On the other hand,
the inflammation from corrosive subli-
mate, however introduced, affects chiefly
the upper part of the intestinal tube.
Baillie and Jager noticed this difference
between arsenic and corrosive sublimate;
a difference which illustrates the doctrine
of specific irritabilities. For the same
reason, if we wash our hands in a de-
coction of aloes it acts on the rectum,
because the irritability of the latter is
adapted to its influence.

The pain arising from arsenic is not
inflammatory but spasmodic. I poisoned
a dog with it, and the animal relieved the
pain by pressing the abdomen against a
projecting object. A poison must not
necessarily be absorbed in order to pro-
duce its effect; for it may act by sym-^upa-

thy, the stimulus being conveyed probably by the respiratory nerves. I question whether the poison of hydrophobia is absorbed, for it always produces a local disease, before the constitutional effects manifest themselves, although the wound may have healed. The following is a tabular view of poisons, adapted to the "physiological classification of diseases." (See the London Medical and Surgical Journal, Vol. 6,—No. 148, Page 551). It is divided into three parts.—1, Diseases, and the principal poisons which produce them. 2, Poisons and the principal diseases which they produce. 3, Principal tests of poisons.

PART I.

DISEASES, AND THE PRINCIPAL POISONS WHICH PRODUCE THEM.

Organic Diseases.

Bronchitis.—Chlorine.

Inflammation of the gullet.—Viruses, meloe, atropa, euphorbia, aconitum, ranunculus, iodine, oxalic acid, sulphuric acid, nitric acid, ammonia, lime, potassa, powder of arsenic, powder of mercury.

Gastro-enteritis.—Viruses and venoms, meloe, honey, atropa, datura, strychnos, conium, cicuta, colchicum, laurus, euphorbia, hydrocyanic acid, aconitum, helleborus, ranunculus, digitalis, cucumis, momordica, menispermum, juniperus, veratrum, agaricus, iodine, chlorine, oxalic acid, phosphorus, sulphuric acid, hydrosulphuric acid, nitric acid, ammonia, lime, baryta, potassa, powder of zinc, tin, arsenic, antimony, copper mercury silver, and gold.

Cystitis.—Meloe, arsenic, mercury.

Glossitis.—Arum, oxalic acid, sulphuric acid, nitric acid, powder of arsenic and mercury.

Urticaria.—Viruses, datura.

Phlegmasia dolens.—Viruses and venoms.

Arachnitis.—Viruses and venoms meloe, honey, alcohol, cicuta, colchicum, laurus, helleborus, veratrum, agaricus, carbonic oxide, sulphurous acid, powder of antimony.

Jaundice.—Viruses and venoms.

Dysentery.—Cucumis, helleborus, juniperus, arsenic.

Catarrh.—Viruses.

Ptyalism.—Digitalis, iodine, nitric acid, powder of mercury and gold.

Hæmoptysis.—Chlorine.

Hæmatemesis.—Meloe, oxalic acid, sulphuric acid, nitric acid, powder of arsenic, and mercury.

Hæmorrhoids.—Meloe, cucumis, momordica, juniperus.

Hæmaturia.—Meloe.

Purpura.—Venoms.

Tympanites.—Agaricus, Powder of arsenic.

Pneumatosis.—Venoms.

Functional Diseases.

Colic.—Powder of lead.

Priapism.—Meloe, datura, Powder of arsenic.

Tetanus.—Venoms, secale, datura, strychnos, brucia, cicuta, hydrocyanic acid, aconitum, ranunculus, Powder of arsenic, antimony and lead.

Insanity.—Meloe, hyoscyamus, atropa, datura, conium, aconitum.

Delirium tremens.—Lolium, alcohol, hyoscyamus, atropa, datura, nicotiana, powder of mercury.

Epilepsy.—Viruses, honey, secale, nicotiana, conium, cicuta, colchicum, laurus, hydrocyanic acid, papaver, helleborus, digitalis, arum, memispermum, veratrum, agaricus, carbonic oxide, phosphorus, hydrosulphuric acid, nitrous oxide, baryta, powder of arsenic, antimony, lead, copper, mercury, silver, and gold.

Syncope.—Atropa, nicotiana, powder of mercury.

Amaurosis.—Hyoscyamus, atropa, datura, cicuta, carbonic oxide.

Idiotism.—Datura, aconitum.

Nervous apoplexy.—Secale, alcohol, hyoscyamus, atropa, datura, nicotiana, strychnos, brucia, conium, cicuta, laurus, hydrocyanic acid, papaver, digitalis, agaricus, carbonic oxide, carburetted hydrogen, sulphurous acid, hydrosulphuric acid, nitrous oxide, baryta, powder of arsenic, antimony, lead, copper, mercury, and silver.

Local palsy.—Powder of lead.

PART II.

POISONS, AND THE PRINCIPAL DISEASES WHICH THEY PRODUCE.

Animal Poisons.

Capra, bos, sus, ornithorhynchus.—phlegmasia, dolens, tetanus.

Phasianus.—Gastro-enteritis.

Rana, cohiber, crotalus, boa.—Gastro-enteritis, phlegmasia dolens, arachnitis, jaundice, purpura, pneumatosis.

Balistes, tetrodon, murena, coryphæna, spams, clupæa.—Inflammation of the gullet, gastro-enteritis, urticaria, arachnitis, jaundice, catarrh, epilepsy.

Meloe.—Inflammation of the gullet,

gastro-enteritis, cystitis, arachnitis, hæmatemesis, hæmorrhoids, hæmaturia, priapism, insanity.

Apis (honey).—Gastro-enteritis, arachnitis, epilepsy.

Aranea, *scorpio*, *cancer*, *scolopendra*.—Gastro-enteritis, phlegmasia dolens, arachnitis, jaundice, purpura, pneumatosis.

Ostrea mytilus.—Inflammation of the gullet, gastro-enteritis, urticaria, arachnitis, jaundice, catarrh, epilepsy.

Vegetable Poisons.

Secale.—Gastro-enteritis, tetanus, epilepsy, nervous apoplexy.

Lolium.—Gastro-enteritis, delirium, tremens.

Hordeum (alcohol).—Arachnitis, delirium tremens, nervous apoplexy.

Hyoscyamus.—Insanity, delirium, tremens, amaurosis, nervous apoplexy.

Atropa.—Inflammation of the gullet, gastro-enteritis, delirium, tremens, syncope, amaurosis, nervous apoplexy.

Datura.—Gastro-enteritis, urticaria, priapism, tetanus, insanity, delirium, tremens, amaurosis, idiotism, nervous apoplexy.

Nicotiana.—Gastro-enteritis, delirium, tremens, epilepsy, syncope, nervous apoplexy.

Strychnos.—Gastro-enteritis, tetanus, nervous apoplexy.

Brucia.—Gastro-enteritis, tetanus, nervous apoplexy.

Conium.—Gastro-enteritis, insanity, epilepsy, nervous apoplexy.

Cicuta.—Gastro-enteritis, arachnitis, tetanus, epilepsy, amaurosis, nervous apoplexy.

Colchicum.—Gastro-enteritis, arachnitis, epilepsy.

Laurus.—Gastro-enteritis, arachnitis, syncope, epilepsy, nervous apoplexy.

Euphorbia.—Inflammation of the gullet, gastro-enteritis.

Amygdalus (hydrocyanic acid).—Gastro-enteritis, tetanus, epilepsy, nervous apoplexy.

Papaver.—Epilepsy, nervous apoplexy.

Aconitum.—Inflammation of the gullet, gastro-enteritis, tetanus, insanity, idiotism.

Helleborus.—Gastro-enteritis, arachnitis, dysentery, epilepsy.

Ranunculus.—Inflammation of the gullet, gastro-enteritis, tetanus.

Digitalis.—Gastro-enteritis, ptialism, syncope, epilepsy.

Arum.—Glossitis, epilepsy.

Cucumis.—Gastro-enteritis, dysentery, hæmorrhoids.

Mormordica.—Gastro-enteritis, dysentery, hæmorrhoids.

Menispermum.—Gastro-enteritis, epilepsy.

Juniperus.—Gastro-enteritis, dysentery, hæmorrhoids.

Veratrum.—Gastro-enteritis, arachnitis, epilepsy.

Agricus.—Gastro-enteritis, sympanites, epilepsy, nervous apoplexy.

MINERAL POISONS.

Iodine, *Hydriodate of potash*.—Inflammation of the gullet, gastro-enteritis, ptialism.

Chlorine.—Bronchitis, gastro-enteritis, hæmoptysis.

Carbonic oxide, *carbonic acid*.—Arachnitis, epilepsy, amaurosis, nervous apoplexy.

Oxalic acid, *oxalate of potash*.—Inflammation of the gullet, gastro-enteritis, glossitis, hæmatemesis.

Carburetted hydrogen.—Nervous apoplexy.

Phosphorus.—Gastro-enteritis, epilepsy.

Sulphurous acid.—Arachnitis, nervous apoplexy.

Sulphuric acid.—Inflammation of the gullet, gastro-enteritis, glossitis, hæmatemesis.

Hydro-sulphuric acid, *hydro-sulphuret of potash*.—Gastro-enteritis, epilepsy, nervous apoplexy.

Nitrous oxide.—Epilepsy, nervous apoplexy.

Nitric acid, *nitrate of potash*.—Inflammation of the gullet, gastro-enteritis, glossitis, hæmatemesis.

Ammonia.—Inflammation of the gullet, gastro-enteritis.

Lime.—Inflammation of the gullet, gastro-enteritis.

Baryta, *carbonate of baryta*, *muriate of baryta*.—Gastro-enteritis, epilepsy.

Potassa, *subcarbonate of potash*.—Inflammation of the gullet, gastro-enteritis.

Sulphate of zinc.—Gastro-enteritis.

Muriate of tin.—Gastro-enteritis.

Black oxide of arsenic, *arsenious acid*, *arsenite of potash*, *arsenic acid*, *arsenate of potash*, *arsenuretted hydrogen*, *sulphurets of arsenic*.—Inflammation of the gullet, gastro-enteritis, cystitis, glossitis, dysentery, hæmatemesis, sympanites, priapism, tetanus, epilepsy, nervous apoplexy.

Oxide of antimony, *tartrate of antimony*.—Gastro-enteritis, arachnitis, tetanus, epilepsy, nervous apoplexy.

Oxide of lead, *carbonate of lead*, *acetate*

of lead.—Colic, epilepsy, tetanus, local palsy.

Carbonate of copper, acetate of copper, sulphate of copper.—Gastro-enteritis, epilepsy.

Oxide of mercury, muriate of mercury.—Inflammation of the gullet, gastro-enteritis, cystitis, glossitis, pyalism, hæmatemesia, delirium, tremors, epilepsy, syncope.

Nitrate of silver.—Gastro-enteritis, epilepsy.

Muriate of gold.—Gastro-enteritis, pyalism, epilepsy.

PART III.

PRINCIPAL TESTS OF POISONS.

Ferrocyanate of potash—morphia—gallic acid—hydriodate of potash—hydrochloric acid—perchloric acid—sulphuric acid—hydrosulphuric acid—hydrosulphuret of ammonia—nitric acid—ammonia—lime—potassa—carbonate of potash—chromate of potash—phosphate of soda—zinc—iron—permuriate of iron—proto-sulphate of iron—tin—proto-muriate of tin—arsenite of potash—acetate of lead—sulphate of copper—ammoniac—sulphate of copper—permuriate of mercury—protonitrate of mercury—nitrate of silver—ammoniac—nitrate of silver—muriate of gold—muriate of platinum.

4. *Sympathy*.—It is to sympathy that Roupil, in his review of Broussais, attributes critical discharges. He considers them to be, not the cause, but the effect of the cessation of diseased action. This is the best account that has been given of them. Scrofula was attributed to sympathy by the oldest Egyptian practitioners; and Broussais and Marshall Hall have lately done the same. Diseases of the skin have been referred to the same cause, by Hippocrates, De Haen, Abernethy, Alibert, Bateman, &c. Insanity was long ago attributed to it, and the opinion is very prevalent now. Rheumatism and gout were referred to it by Hoffman and Scudamore, and chorea by Sydenham. Hydrocephalus, in its first stage, is very closely imitated by worms in the intestinal canal, which shows the sympathy between the intestines and the brain. Ophthalmia, tetanus, hysteria, scrofula, and tabes mesenterica, all furnish examples of sympathy. The stomach has the respiratory system of nerves very largely distributed on it, and therefore its extensive sympathy. The skin, for instance, is very irritable after a debauch, so that it is generally cut during

the operation of shaving. It may be asked why the lungs do not sympathize more with the stomach, seeing how closely they are connected by the nerves which are distributed to them. But we must look, not only at the mode of communication, but also at the character of the original irritation.

Every disease has been referred to gastro-enteritis; but we cannot, with propriety, refer all diseases to gastro-enteritis under the same form. It may be the key to their pathology; but it is not their pathology altogether. I go a long way with Broussais; but his views are too exclusive. I think diseases may arise from different causes.

Fevers, from local irritation, furnish one of the best examples of sympathy, as an exciting cause of disease. Indeed, it is a question whether fevers are not always sympathetic. They were long thought to be idiopathic; but Fordyce observed that all parts of the body were not affected alike by them. These local affections, however, were thought to be the consequences, and not the cause of the fever, till Beddoes and Clutterbuck attributed fever, in every case, to a local cause. Broussais followed up this view in 1808. Hunter had remarked that every cause tending to produce fever was efficacious in the direct ratio of its connection with the stomach and bowels. Mills, in his work on the propriety of bleeding in fever, referred the disease to different organs, in different cases; and Armstrong, Cheyne, Duncan, Graham, and Bateman supported this view.

5. *The passions*.—The passions act in the same way as sympathy, in producing disease, but they differ in having the primary irritation always in the brain. The division of the passions into stimulant and sedative is ill founded. There is no question but they all act as stimulants. It is only their permanent effect we have to consider, in the production of disease.

The diseases which have been attributed to the passions are arachnitis, which produces serous apoplexy, incubus, insanity, idiotism, nervous apoplexy, catalepsy, cynanche tonsillaris, gout, biliary calculi, and jaundice. It was well known by the earliest authors, that jealousy will produce jaundice. Diarrhoea and dysentery do not take place merely from the relaxation of the sphincter ani; but from fear. Polysarcia, hæmoptysis, and epistaxis, are also attributable to the passions. The last is so common a result of

anger, that the Hebrews thought the seat of that passion was in the nose. The following diseases are likewise referred to the passions:—*scorbutus*, *angina pectoris*, palpitation of the heart, *syncope*, *dyspepsia*, *chlorosis*, *anemia*, palsy of the tongue, *epilepsy* and *hysteria*.

6. *Pressure*.—The principal diseases to which pressure gives rise are inflammation, induration, atrophy, adhesion of contiguous surfaces, strictures, &c.

7. *Blows*.—These may give rise to a great variety of diseases, which may be included under the terms fractures, dislocations, contusions, inflammation, *hernia*, extravasation of blood, &c.

8. *Wounds*.—According to Abernethy and the best writers, wounds and other causes which produce tetanus act first by causing gastro-enteritis, and afterwards tetanus by sympathy. It may be objected to the sympathetic effects of wounds and other causes, that less sympathetic effects are sometimes displayed by parts, which are the most connected by nerves. But in this case the primary irritation may not be adapted to the specific irritability of the part secondarily affected.

Some venoms and viruses are able to abrade the cuticle, and thus to affect the system; but most of them do not act when applied to the mucous membrane of intestines or lungs, or to the cuticle; but must be introduced beneath the latter. They come therefore to be considered under the head of "wounds." Poisons which act when swallowed, have already been spoken of under the head of "aliment."

All fatal venoms kill by nervous apoplexy. The principal venomous animals are the snakes of India, the viper, the wasp, the bee, the gnat, and the scorpion. The bite of the tarantula gives a tendency to a kind of convulsion, which has been represented to be like dancing. The principal viruses are gonorrhoea, lues venerea, molluscum, vaccina, porrigo, variola, scabies, frambesia, hospital gangrene, and hydrophobia. There is also great danger from dissection-wounds; owing to the secretions having been vitiated when dying. Gangrene acts like a poison; the dead mass being in contact with living parts.

The diseases produced by these viruses, are said to be from vitiation of the blood; but no change can be detected in it; nor will such blood produce similar diseases by inoculation. Jesse Foot said that syphilis might be communicated by inoculation with the blood; but Hunter

proved that it could not. In the cases which have been reported of children being born affected with syphilis, I think it was not really that disease, or else that it was communicated from the passages of the mother, while coming into the world, or afterwards from the nurse, not by the milk, but by infected nipples. If these viruses were in the blood, all parts of the body would be attacked, and the latent stage which occurs in many of the diseases caused by them is incompatible with the theory of their being produced by vitiation of the blood. Hydrophobia has sometimes been produced by pure fright, and therefore other diseases of the same kind may. Hunter said that the inoculated small-pox was milder than the natural, because less of the poison was introduced, but we know how much is introduced, or if any at all. Adam says, that when the small-pox is taken naturally it proves the existence of a predisposition to the disease, which co-operates with it instead of resisting it, as the constitution does when the disease is forced on it by inoculation. This is a good explanation; but, probably, the true one is, that from the concentrated state in which the poison is introduced by inoculation, the contraction of the vessels is so great, as to be incompatible with the long continuance of that contraction. In this respect it resembles snuff, while *asarum*, which is a milder stimulus, has a longer latent stage. The manner in which cow-pox secures from small-pox is probably by destroying the specific irritability of the parts affected. The poison of the viper has been proved by Fontana to be quite bland.

9. *Suppressed secretions*.—If secretions are suppressed, it implies that there is increased irritation, and this, by sympathy, may cause irritation in another part. Suppressed perspiration may produce catarrh, suppressed nasal mucus, ophthalmia, and serous apoplexy, suppressed menses, hemorrhage from some other part, and suppressed lochia, insanity. Persons long accustomed to snuff, may go mad if they leave it off suddenly, for the constant discharge of mucus implies diminished irritation; and, if it be suddenly stopped, it may give rise to an increased irritation, which the parts cannot bear.

10. *Retained Secretions*.—The principal of these are bile, feces, urine, and milk. Retained bile may give rise to jaundice, retained feces to dysentery, hemorrhoids, and prolapsus ani; retained

urine to calculi, or paralysis of the bladder; and retained milk to inflammation of the mamma. The secondary effects from retained secretions may be, from the urine, arachnitis, and from the feces, insanity, epilepsy, chorea, hysteria, and tenanus.

11. *Exercise*.—If, during expiration, all the functions of the body are performed with greater vigour, it may be wrong, in the case of diseased lungs, to expose them to this greater stimulus. Phthisical lungs may be strengthened by moderate exercise, but may become rapidly diseased if the exercise be violent. Too little exercise will give rise to scorbutus, chlorosis, &c. Stalled oxen are frequently found to have biliary calculi, and if geese are confined, their liver becomes diseased.

12. *Sleep*.—Too much sleep causes polysarcia, angina pectoris, apoplexy, and the other diseases which are occasioned by too much food. Too little sleep has the same effect as too much exercise. It leads to insanity, fever, and all the diseases which flow from too much excitement.

LECTURES ON SURGERY,

BY

JOHN HUNTER, F.R.S.

OF THE BRAIN AND NERVES.

Passive and active states of the Brain—too much influence attributed to the Brain in the bodily actions—actions of the Brain—five modes of impression on the Nerves, or the Senses.—Voluntary action becoming involuntary, as in chorea.—Of Sensation—Connexion of the Brain and Nerves with Life.—Of Sleep—its importance in the animal economy.

We have hitherto traced animal matter from its change from common matter to animal substance, the particles of which have possessed such an arrangement as to produce life; still it has other modes of arrangement, out of which arise other modes of action, and which only take place in some animals. These are the brain and nerves, which produce sensation, out of which arise mind and reason; for the mind could not be formed, nor could we reason without sensation; it being always about some object that the mind is affected, or that we reason.

The brain is passive in sensation, only

receiving the impression from the nerves, according to their actions called so many sensations.—In mind it is active. Mind arises from a peculiar quality in the sensation, being expressive of some quality in the body which is the object of sensation, and which gives an action to the brain answering to those qualities, as agreeable and disagreeable, with all their different species, as love, joy, hatred, anger, &c.; which actions of the brain, or states of the mind, become the causes of particular modes of action in the body affecting both involuntary and voluntary actions. The heart beats quick or slow according to those states; sickness may be produced; purging, contraction of the bladder will take place; the voluntary muscles hardly obeying the will, but performing involuntary actions, according to the state of the mind.

Reason, by influencing the will becomes the cause of the voluntary actions, and by this connexion all these principles can affect one another.

Now the brain appears to be capable of two modes of action, and out of these arises every property of the brain. We may call the actions of the brain mind; objects affect our senses so as to form a peculiar state of mind, this I call mental impression. Again, the mind can reason and exercise volition respecting objects. The former is involuntary, and belongs also to brutes: the latter is voluntary. For instance, I am challenged to fight a duel, volition and reason determine me to go to it; but when at the place, my joints tremble, my stomach turns sick; this is the effect of mental impression or feelings of the mind. The two operations are very different, and in general the feelings of the mind, if strong, will prevent all reasoning.

Much more has been ascribed to the brain and nerves than they deserve. They have been thought to be the cause of every property in an animal body; that independent of them the whole body was a dead machine, and that it was only put in action by them.

But although their actions are absolutely necessary in the machine, they are not so universally so as has been imagined. They are not the cause of growth, nor do they even preserve a part from death, although the whole as a whole cannot live without them.

The nerves have but one mode of action, namely, that of conveying impressions; but this in two different directions, one from their extremities in the

body, towards the brain, conveying impressions made on them to the brain, in order to excite actions suitable to these impressions; the other from the brain to the extremities, conveying the mandates of the will, &c.

The mode of action which is from the body towards the brain is of two kinds: one is the internal feel of the body, of perfection, imperfection, power, want, &c. The other is of those feelings of the body which are to call forth the powers of the will to perform what are called voluntary actions for the subsistence of the body, or to effect the actions which it cannot perform.

The actions of the brain towards the body are also of two kinds: one in consequence of the feelings or state of the mind at the time, whether the actions of fear, courage, anger, love, &c.; the other in consequence of the command of the will, called voluntary actions.

Those of the body to the brain are the first in order, for it is the receiving the impressions that gives rise to the others. Of the latter, the first are the feelings of the mind, and the second the will and its consequences, namely, voluntary actions, or all those actions directed principally to external objects, for which muscles are provided.

As the nerves are perfectly passive till impressed by external objects, no one could have any sensation except while an impression is made on some of the senses. Therefore a man could not feel that he exists but in thought; nor could he do that if he had never received impressions to think about, for thinking is no more than the memory of impressions put into order by the mind; nor should he have those actions which naturally arise from the brain till the brain makes the impression on the nerves.

The impression is made on the body, but the sensation is in the brain, for the effect (of a person's feeling in a part to which a nerve is distributed) on cutting or otherwise injuring a nerve, proves that sensation is in the brain and not in the body; for if it was in the body, the sensation would be referred to the part injured; but sensation being in the brain and brought from the brain by the action of the nerves, or sensation being formerly in the brain, the action of the nerves we find is referred to the beginnings of that action by the combination of the other senses; otherwise it would be only in possession of the sensation without any

reference; the reference produces a feeling in the mind receiving sensation by joining it with the seat of impression.

There are five modes of impression on nerves, or perhaps rather five modes of construction of parts, which are adapted to so many kinds of impression. These are called the five senses; but there are a great many kinds of sensation conveyed to the brain or sensorium.

The five senses are no more than parts constructed so as to be capable of receiving impressions, or so many properties of matter. Perhaps all are capable of receiving the impression of touch, or pressure, if it could be applied to all, so that every nerve may be said to feel.

But besides pressure, there are other properties of matter. Many bodies have qualities besides being tangible; some only when in solution making an impression on the tongue and causing taste; the same bodies when thrown into vapour give smell; air, besides being tangible, has a peculiar motion, arising from its repulsive quality, called vibration, which strikes the ear and produces hearing. There arises another property in another species of matter, called light, which we know less of than any other, which has a power of pervading some bodies called transparent, and gives us the sensation of sight; and from peculiarity in the formation of those transparent parts light becomes more determined in its direction.

The sensation of the glans, penis, tickling, and itching would seem to belong to feeling. The first, however, is certainly a different mode of action of the nerve from common feeling, and both itching and tickling require a particular mode of impression to produce them.

An animal can bear with ease a certain quantity of common sensation, which quantity being particularly applied will give pleasure; but if common sensation be increased beyond certain bounds, it gives great pain; so that pain is no more than an increased sensation, such as the sense of violence committed to a part.

All the five senses are subject to the same mode of sensation when applied in the same way, namely, by touch, and if the impression is so strong, give the sensation of pain. For instance, if the retina be hurt it gives pain, but not light; if the ear be hurt it gives pain, but not sound; if the nose be hurt it gives pain, but not smell. But there are exceptions to the two first, for a blow on the eye often produces light, and on the ear sound. And

besides, these senses are subject to diseases, here the sensation often arises without impression from without.

The common actions of the body, that commonly arise from the will, often become involuntary, as in palsies, St. Vitus's dance, &c.; but I suspect that these actions still arise from the brain or mind, though not the will, because they do not take place in sleep; nor do we find the same diseases in any animal but the human.

Our senses being such, have their peculiar degree of sensation and their peculiar mode of receiving impressions, and when this is carried to too great a length, they become extremely uneasy: but it is an uneasiness different from pain: it is the peculiar sense carried beyond what the mind can bear.

Sensation is in proportion to the impression made on a part, joined with the susceptibility with which the nerve is ready to act. But for distinct sensation two things are necessary, namely, time and space. It is necessary that the impression should be some time in performing, because an impression may be too quick to excite sensation, or quicker than any action in the nerves, such as a ball passing through a man's body without his feeling it; but he is capable of feeling it afterwards, which arises from an action of the injured part, not from the violence itself. Neither must the time be too long, for an impression or an injury may be so slow as not to affect the nerves at all, so as to throw them into any action. A person, for instance, shall become dropsical, and the belly shall fill with water so gradually as to give no pain from the stretching of the muscles, peritoneum, &c.; but if you were to attempt to stretch the belly of another person in a given time to such a degree, it would produce pain in proportion to the violence.

The space must also be determined, for a given quantity of impression may be concentrated so as to be within bounds of sensation; for it would appear that a single nerve, or a very few nerves, are not capable of conveying sensation, however affected; for instance, a given quantity of light may be concentrated into such a small point as not to be seen.

Every sensation, every mode of sensation, and every sense appear to depend on the quantity of nerves acted upon, and in a given time; therefore we have a great quantity of nerves going to parts that are allotted for strong sensation, that no im-

pression may be made without affecting a great many nerves at the same time.

The uneasiness arising from too strong impressions we can easily assign a reason for, as it becomes a means of avoiding that violence; but itching and tickling appear not to be so very necessary: however they must be of service in the animal œconomy. I can conceive itching becomes a cause of our keeping ourselves clean, free from vermin, &c., and becomes a substitute for pain: it naturally leads us to the cure, which gives pleasure; and the performance of it is almost similar to the indulgence of our natural appetites.

This principle of sensation is our director with respect to all other external actions, but has no absolute power over the internal œconomy of the machine. But this first principle we shall find can influence the others very materially, and thus a compound principle will be produced.

The brain and nerves also give the body a consciousness of its own muscular powers. This is more remarkable in other animals than in man: thus, a horse will at once know what he can leap, and will leap no more, nor attempt it; and, indeed, a man can for the most part tell. A nobleman, (the Duke of Queensbury) who had broken his tendo Achillis was fearful of walking about his room; but I advised him to do it as well as he could, assuring him that his gastrocnemus muscle, knowing its own business better than its master, would refuse to act if he walked, and that the action would be performed by other muscles. This he found to be true. But in the night time, I told him I could not be answerable for what his muscles would do, therefore I thought proper to put the leg into a fit posture and secure it by a bandage.

As the brain and nerves are composed of animal matter, and as that animal matter has life, or the first principle of action, in common with all the other matter composing the whole body, there arises necessarily an intimate connection between those principles, and, though totally different in their peculiar actions, yet they become blended with each other, so that one seldom acts perfectly unless the other is in perfect order, each of them calling on the other to do its part; and when both these principles are in vigour and in perfect harmony the whole machine is in health.

Life is coeval with the existence of the animal or vegetable matter itself; but sensation is a later principle, does not take

place until birth, when a new economy is set up, in which sensation is called in by the living principle for the support of the whole, beginning first in the stomach by sympathy, and then going on in a series of actions. These compound actions therefore, cannot take place until sensation takes place; and it is reasonable to suppose, that a child in the womb has no sensation, for it is just as well formed in all its parts without brain as with it, and the nerves are indebted to the brain for their formation.*

[Mr. Palmer, in his edition of Hunter's Lectures, offers the following remarks:—

"This statement is incorrect. The nerves may exist without the brain or spinal marrow, which are accessory not the fundamental parts. The same law obtains in regard to the heart and blood-vessels: and indeed it may be observed generally in regard to the progressive development of the higher animals, that at first they follow the type of inferior animals, but afterwards advance to those which are still higher and higher in the zoological scale. Hunter in the main was well acquainted with this law of development as regards the higher animals, as will appear from the following passage, in which we may remark that he has anticipated many of the leading discoveries on this subject by modern anatomists. The passage occurs in the introduction to the description of the drawings relating to incubation. 'If we were capable,' he says, 'of following the progress of increase of the number of the parts of the most perfect animal, as they first formed in succession, from the very first, to its state of full perfection, we should probably be able to compare it to some one of the incomplete animals themselves, of every order of animals in the creation, being at no stage different from some of those inferior orders; or, in other words, if we were to take a series of animals from the more imperfect to the perfect, we should probably find an imperfect animal, corresponding with some stage of the most perfect.' (Hunt. Cat., Phys. Series, vol. ii. p. iv.) Many other passages might be adduced which evince that Mr. Hunter's extensive acquaintance with comparative anatomy had enabled him to deduce the true principles which regulate the formation of the body and the co-existence of the different systems of parts in the same individual organism."]

But the moment a new mode of action takes place, actions arising from sensation must be performed for the support

of this; and an animal must die if these sensations are not produced, which cannot be produced if there is no brain*.

Actions arising from the union of the two principles, life and sensation, are extremely evident; being all those actions which constitute a state of mind, or those feelings of the mind from which instinct arises.

Sleep.—A singular result of our being possessed of the sensitive principle is sleep. Perfect sleep is an annihilation of the power of present sensation, of the power of thinking, and all traces of the past, or what we call memory. We find that there is, of course, a cessation of all voluntary actions; the will itself is in every respect at perfect rest, and we are at this time, in respect to ourselves, in a state of non-existence. But sleep has its degrees; perhaps in all cases there is a considerable loss of these principles, especially sensation; but the effects of sensation are not always lost, namely, those operations of the mind which produce actions which are very nearly voluntary. During sleep, therefore, the mind may be thinking, which forms what we call dreams; but as our present sensations do not become directors of those actions which the mind is employed about, no such action takes place as the mind forms to itself. It is even possible to dream when awake; it is only necessary for the thinking power to take possession of the mind, and proceed with an action with which the present sensation has nothing to do, so that a person neither sees objects, hears sounds, nor feels any thing that touches him; and when the mind ceases to act and sensation returns, we call it a dream. Now, whenever the body loses the consciousness of its own existence, it may be called a waking dream, and this is often the case when people are in deep thought. Sleep appears to be the sensitive, what I have already described to take place in the living principle when I mentioned my own case; but that arose from disease, while sleep is necessary.

When both these principles undergo a cessation of their actions it is called a swoon. Here there is a cessation of all actions which naturally arise in the body, but still a capability of having them reproduced. Now, in a fainting fit there

* Mr. Hunter must have been aware of many examples of fetuses without brains which have lived for some time after birth. He must here mean the medulla oblongata, without which respiration cannot take place.

seems rather a cessation of the actions of sensation, the animal becoming totally insensible to itself; but in a swoon we have this carried further: the cessation takes place not only in the sensitive but in the living principle itself, for we shall have people fall into a trance or swoon, and they shall remain in it without any kind of motion,—respiration, circulation, digestion, and every operation of the body at total rest; and if the disease, or the cause of cessation of that action, should continue a long time, they may lose the power of reproducing this sensation again. Fainting, from bleeding, fear, &c., is a swoon in a certain degree, for these principles are diminished, especially the sensitive. Sleep is not only a cessation of voluntary action, but produces cessation of involuntary action of voluntary parts, arising from their diseases, as in St. Vitus's dance, &c.

Sleep is of such material consequence to the sensitive principle of the constitution—namely, sensation, mind, and will—that it may be said to constitute one third of its duration. As it is only an annihilation of sensation and all its consequences, one might suppose that it was of little consequence to the machine; but it is as essential to it as food.

Sleep, or rather a cessation of sensation, thus taking place, while the action of life is going on, shows that there must be a peculiar structure, and a principle arising out of that structure superadded, making a compound which is endowed with life; for life for a time can go on without sensation, but cannot always go on without it.

Sensation, then, is a fatigue to life; and in proportion to the exertion of sensation, in a given time, the sooner is life wasted. For this reason, when we are in health, sensation stops at proper times; life then appears at ease. This slighter effect of health is often increased preternaturally, as in cases called lethargy.

form of a common couch, with the back inclined at an angle of 45 degrees. The position of the hind legs enables the whole to be inclined backwards by a very gentle force applied at the end to which the vice is fixed: the force of one hand is sufficient to raise it, even with the additional weight of the patient, as the two extremities of the chair are nearly in equilibrio when the fore-part is somewhat raised. By these means the operator is enabled to dispense with an assistant, at least in sounding; as he can, after introducing the catheter with one hand, throw the patient back with the other. The shock communicated to the stone in the patient's bladder can be increased at pleasure; but, in sounding, not much jar is required to dislodge it: the sudden change of position alone is sufficient to make it fall into the back part of the base; where it is readily felt, by carrying the catheter at once backward, and raising the handle nearly as much as the cervix vesicæ will permit. In dislodging fragments, the chair is especially serviceable. The force with which the end can be thrown back on the floor, will detach any fragments that may couch behind the base of the prostate. Besides being admirably adapted to the purpose for which it is principally intended, it is found useful for other surgical purposes in which a sofa may be required. To the lithotrist, such a chair or bed is indispensable: by its aid, he is enabled to discover the calculus more readily, to remove the fragments with more certainty, and to break the stone with more safety and less suffering to the patient.

The sensation which a stone communicates cannot well be mistaken. The sense of touch alone is generally sufficient to decide the presence of a calculus: if there exist a doubt, the ear should be appealed to; and the operator should not be satisfied till he has heard as well as felt the contact between the metallic instrument and the stone. The touch may sometimes mislead when there is a fungus in the bladder, or a portion of the mucuous coat morbidly thickened; in both which cases the symptoms closely resemble those of stone in the bladder. But, in these forms of disease, the ear cannot deceive the surgeon; and the absence of sound, when the foreign body is struck, is sufficient to decide against the existence of calculus. I have found, sometimes, when the friction of the sound over the foreign substance has been equivocal, that the injection of oil into the bladder has removed the deceptive sensation which the contact of metal with a

A PRACTICAL VIEW
OF
LITHOTRITY:
WITH REMARKS ON
THE LATERAL OPERATION OF
LITHOTOMY.

BY MR. ASTON KEY.

(Continued from page 267.)

The chair which I use for this purpose is constructed on the principle of Heurte-
lou's "lit rectangle." It is made in the

fungoid mass surrounded by water will produce. An instance occurred not long since, of a bleeding fungus being mistaken for a calculus. The patient was sounded more than once, by an experienced surgeon, and pronounced to have stone: he was placed under the care of a lithotritist, who fixed a day for the operation. The patient, however, became so ill before the day arrived, that it was necessary to defer the operation. On his death, which took place in a few days afterwards, no stone was discovered in the bladder; but a bleeding fungus, of considerable size, was found attached to the mucous membrane. The occurrence of a cyst enveloping the stone in the bladder, is often held out as likely to mislead the surgeon, and to prevent that satisfactory evidence being obtained that a careful operator would wish to have before proceeding to the operation. The occasional presence of a cyst around a calculus cannot be denied. In a case on which Mr. W. Wickham operated, a something was removed with the stone that resembled a cyst formed by adhesive matter: it was so thin as not to prevent a distinct sensation being communicated by the sound. Such cases are very rare. The stone may also be lodged in a sac formed by a protrusion of the mucous coat between the muscular fibres of the bladder. Such a variation in the position of the stone is seen sometimes. We have a specimen of it in the Museum; but, like the former, it is a very unusual variety in the situation of a vesical calculus. I have never met with such accidents, either in hospital or private practice, nor have I witnessed them in that of my colleagues.

The instruments that are used for the discovery of a calculus are two—the steel sound and the silver catheter. Each has its advantages. The latter has become the more general instrument, since the introduction of lithotritry, on account of its combining the office of the sound with that of injecting the bladder. The best form is that of Heurteloup's catheter: the shortness of its beak enables the surgeon to examine the bladder in all its parts; to reach even its deepest recesses behind an enlarged prostate gland; and to measure, with some degree of certainty, the depth and form of the stone. The beak can be turned in all directions, so as to sweep the lateral parts of the base, as well as the most depending part of the cavity. The sensation, however, conveyed by the hollow silver tube is less distinct than that communicated by a solid steel instru-

ment; and I have known instances where a sound or sensation of an equivocal character has been transmitted by the tube, and where all doubt has been removed by the more accurate impression given by the contact of the sound. Another disadvantage of the catheter is, the alteration that it produces in the course of the canal, by raising the prostate gland. This will be understood by contrasting the straight tube of the catheter with the curve of the sound. When the former is in the bladder, the part of it that lies in the prostatic portion of the urethra is a straight line; and when the hand is depressed, the prostatic portion is necessarily raised, and the *cul de sac* of the bladder anterior to the ureters is deepened. A small stone, or fragments, may then escape the touch of the catheter, unless they can be thrown backward into the base of the bladder. The common steel sound is free from this disadvantage: when the beak is in the bladder, its curved portion is in the prostate gland, and causes no distortion in that part of the canal; so that, as it enters the bladder, a small stone may be struck, over which the silver catheter would pass without touching it. If the bladder contains about an ounce of urine, which is sufficient to allow the sound to enter freely, the stone, however small, rarely eludes it. In the examination of persons suspected to be afflicted with calculus, I usually first employ the catheter, after injecting two or three ounces of warm water, and reclining the chair: and if I do not strike a stone, or if I meet with a something of the nature of which the silver tube fails accurately to inform me, I then allow some of the water to escape, and introduce a common steel instrument. In this way, the most exact information may be obtained of the presence of a foreign body: its size and form, as well as the existence of more than one, can be best ascertained by the catheter; but the sound and vibration are best communicated, in doubtful cases of small stones or fragments, by the solid steel instrument.

The size of the calculus forms of itself no objection to lithotritry. A large stone presents, however, several considerations for the surgeon to weigh, before he undertakes the operation. As the stone cannot be entirely crushed at one sitting, a patient with an irritable or an unsound bladder, becomes involved in most serious danger by the operation being hastily adopted. A large stone broken up into many irregular fragments, all crowded by the

contractions of the bladder against the irritable and inflamed cervix, causes excessive efforts to void the urine, and even inflammation of the mucous surface. Under such circumstances, the repetition of the operation becomes impossible, or highly dangerous; and the patient has to struggle through the stages of inflammation, with a bladder irritated by the lesser fragments. But if the bladder be free from disease, and not very irritable, it will bear the number of sittings required to break up a large stone, without much suffering to the patient, and with very little danger. The success of lithotripsy, like that of most surgical operations, mainly depends on its subject. If the constitution be good, and the power of endurance great, difficulties of most unpromising nature may be overcome. We should therefore pay more regard to the general condition of the patient, and of his bladder, than to the size of the stone, and inquire minutely into the several circumstances likely to have an influence on the result of the operation.

One of the earliest cases in which I operated was that of a Mr. T—, of unhealthy constitution, much worn down by his continued sufferings, and by calculous affection of the kidneys. The stone was so large, that, taken with other circumstances, it induced a very experienced surgeon to give an opinion adverse to lithotripsy. The patient's decided objection to lithotomy, however, left me no alternative; and by proceeding with caution, I broke up the stone, after not fewer than sixteen sittings. The irritability of his bladder decreased as the stone became diminished in volume and the fragments expelled. I know of no limits to the size of a calculus removable by lithotripsy, but the power of the lithotrite. If a powerful instrument can be brought to embrace it, and the organ be healthy, the operation may, as far as my experience goes, be attempted with propriety.

The different ages of patients to be submitted to the lithotrite or the knife are remarkably contrasted with one another. Whilst in youth and advanced age the latter is more suitable, the former is found to be generally better adapted to the middle period between puberty and the decline of life. We have seen, in speaking of lithotomy, that persons whose sexual organs are completely developed, are more liable to the accidents attending the use of the knife, than children whose organs are not yet evolved; or than the aged, whose irritability is on the wane. The

full-grown healthy adult, on the contrary, presents all the conditions most favourable for crushing the calculus. The canal is sufficiently large to admit an instrument efficient from its size: the prostate gland also is usually healthy, and free from the enlargement of age; thus rendering the neck of the bladder, a part so important in the operation, little exposed to the dangers of inflammation. When there is a normal prostate gland, the operator may manipulate his instrument without risk of bruising or otherwise injuring this most sensitive of all the parts concerned in the operation. The urethra of such patients being more free, the fragments are expelled with less difficulty, and cause less pain in their expulsion, which is also materially assisted by a sound and vigorous bladder. At this age, also, inflammation, should it supervene, is more easily controlled than in the aged subject, who cannot well bear depletion. The warm bath and free venesection speedily arrest the inflammation of the mucous membrane of the bladder; but the old are soon depressed by the diseased action, as well as by the measures required for its suppression. Inflammation, however, is less likely to occur in such healthy subjects, where the parts are not mechanically injured by the operation, and when the patient has been prepared by dietetic and other prudential measures. The aged subject, however, is not less adapted to the operation than the younger adults, if he be free from the common accidents of age—as an enlarged prostate, accompanied with an irritable state of bladder. If the parts in the aged are sound, the operation is especially successful in them; as there is less irritability in the organs of generation, and less excitability of the general system. The urethra, also, is usually larger; and if the neck of the bladder be free, it allows fragments of extraordinary size to pass. I have in my possession a piece of calculus passed by an elderly gentleman, $8\frac{1}{2}$ lines in length, and $4\frac{1}{2}$ across: it is a piece of phosphatic calculus, broken off by the first application of the percussor, and rendered smooth at its angles and edges by undergoing attrition in the bladder for three weeks. It even passed without difficulty or pain. In the old subject, however, difficulties often present themselves in consequence of the change which the parts about the neck of the bladder undergo, and the unsound condition of the bladder itself consequent on these changes. The operation in such persons is rendered dangerous by the in-

inflammatory disposition of the organ, and by the difficulty with which the fragments make their way through the prostatic portion of the canal.

The state of the bladder is perhaps, of all the circumstances that the lithotritist has to consider, the most important; and one on which the propriety of performing the operation will mainly hinge. Three conditions of this organ are necessary; and these must be ascertained, by preliminary observations and trials, before the operation is determined on:—1st, It must be capable of holding a sufficient quantity of water to facilitate the working of the percussor. 2dly, It must be free from that extreme irritability that often attends the latter stages of calculous disorders: and, 3dly, Not prone to inflammation, from slight excitement. In healthy persons, the bladder, even under the irritation of a stone, will allow several ounces of water to be injected into its cavity, without sustaining more than a slight inclination to eject it. Its retentive powers are not impaired in the early stages of the disorder: patients will go for many hours without any desire to empty the bladder, the only early symptom being a smarting, when the bladder contracts on the calculus. It is therefore rare to meet with any difficulty in injecting water sufficient for the purpose of giving space for the operation, among those who apply for advice soon after the symptoms have begun to declare themselves.

Even when, from the long-continued presence of the stone, the bladder becomes morbidly affected, and able to contain but three or four ounces of urine without an irresistible desire to expel it, much may be done, by treatment, to assuage the irritation of the mucous membrane, and tranquillize the muscular excitability. When the stone has been long resident in the bladder, and has produced a change in the mucous membrane and a copious discharge of phosphatic mucus, signs of extreme irritability come on, and almost seem to forbid any expectation of lithotritry being practicable. The desire to void urine is renewed every two hours, or oftener: the urine not only deposits a large quantity of dark-coloured mucus, but is cloudy, and loaded with small flakes of adhesive matter, the result of inflammation of the mucous lining: the pain in expelling the last few drops of mucus is intense. Such continued suffering at length affects the general health; and would seem, I say, to forbid the operation altogether. Frequently, however, will

these formidable symptoms yield to a system of diet and medicine, and the patient by degrees be unexpectedly brought into a condition to bear the operation. Two summers ago, I was consulted by a gentleman who for more than three years had experienced symptoms of stone in the bladder; which had of late increased so much, as nearly to confine him to the house. I sounded him, and discovered a stone grasped closely by a very irritable and tender bladder. On injecting, or rather attempting to inject, a small quantity of water, he complained of excessive pain from the slightest pressure on the piston of the syringe; and I endeavoured in vain to overcome the resistance of the bladder. His urine was high-coloured, and loaded with a copious secretion of a dark bloody mucus: his pulse was quick, and tongue furred. The slight examination that I made of his bladder was followed by severe rigors and fever, which remained upon him for several days. So untoward a case appeared to hold out but little prospect of being benefited by lithotritry. He was ordered to employ a mild form of diet, to abstain from all fermented liquors, and to take saline medicines, with the alkali predominating. In three months, his symptoms had so far improved, and the irritability of the bladder was so much diminished, that I crushed four calculi with very little disturbance of his system, and with decided amelioration of his vesical irritation. Instead of the mucous secretion being increased by the operation, or the desire to void urine becoming more frequent, both these symptoms were relieved; and the fragments of lithic acid were entirely discharged from the bladder, with as little irritation as I ever witnessed after an operation. An opinion cannot be formed of the real condition of the bladder by one sounding, or once injecting the bladder. Those who have irritable bladders usually experience some form of irritation, after moderate distension with water, and examination with the catheter. It generally assumes the form of rigor, occurring once or more in the twenty-four hours after the examination has been made, and followed by severe pyrexia, that lasts for several days. The rigor of itself indicates the degree of irritation produced by the sound; and if not followed by the hot stage of fever, it indicates nothing more: but the presence of pyrexia is evidence of inflammation taking place; and such a state is most unfavourable to lithotritry. A distinction, there-

fore, is to be drawn between these two states: the occurrence of a rigor need not deter the surgeon from commencing the operation—it often attends the first examination, and may never recur; but the indication of inflammation, drawn from a continued state of pyrexia, should at once induce him to defer the operation, until, by withdrawing all stimuli, he has brought the bladder into a tranquil state. This disposition to inflammation is often kept up by improper food, especially drink; and is indicated by a plethoric condition of the system, and a flushed countenance. Such a condition may be overcome; and is unlike that state of bladder which is the effect of commencing disorganization, and often associated with diseased kidneys. This state of organs is also attended by the same degree of irritability, the same bloody mucous deposit after sounding, and the same accompanying fever: but the constitution presents not the healthy aspect of temporary excitement; there is generally more pallor of countenance, amounting to a pasty state of the skin, with an occasional streak or patch of colour.

A gentleman with symptoms of stone came to town, to place himself under my care, carrying plenty of flesh, but with an appearance of depression strongly characteristic of something more than the irritation caused by the presence of a stone in the bladder, as his symptoms otherwise were not more urgent than the disease often excites in a healthy subject. His urine was much loaded with mucus, which, under exercise, assumed a bloody tint; and the pulse was quick, without any external cause of excitement to make it rise. The bladder refused to receive more than an ounce of water by injection, and that gave him severe pain: this was followed by a slight rigor. From day to day I examined the state of his water, and found it uniformly of a dark colour; the lower third of the utensil was filled with mucus of an unhealthy character; and pyrexia was present, though not of a severe form. No improvement took place in his symptoms, under the plan of medicine and diet that I prescribed for him: and as there was no appearance of his being able to undergo any operation in a short period of time, I advised him to return into the country, and, under the treatment of his medical attendant, to obtain all the relief he could, before the operation was performed. He made no complaint of pain in his loins, except after more than usual exercise, and on

the occasion of attending the musical festival in Westminster Abbey. He became worse after his return home, and in a short time he died. Mr. Jubb, of Halifax, inspected his body; and found the kidneys greatly disorganized, absorption of the tubular structure to a great extent, and the pelvis of each kidney filled with a puriform secretion. In the bladder were found three stones of a considerable size.

One principal source of irritability of the bladder is a morbid condition of the cervix or of the prostate gland. The structure about the neck of the bladder, above all others deserves the especial attention of the lithotritist; as it is here that he will meet with the most difficulties, and will also find the chief source of danger. The extreme susceptibility of this part of the bladder is not unfrequently evinced in severe rigor, and inflammation following the introduction of a sound in patients who complain of dysuria connected with an enlarged prostate gland. These persons, often highly disposed to inflammation, have a severe attack, brought on by the casual introduction of an instrument for the purpose of ascertaining the cause of their ailments. When the morbid condition of the gland is combined with calculus, the risk of inflammation, and the danger of its consequences, become greatly increased; and the hasty performance of lithotomy in persons not prepared for the operation has been known to induce a fatal cystitis. Too much caution cannot be used in ascertaining the exact condition of the neck of the bladder, by occasional examination with the sound, not only with the view of learning the physical state of the gland, but also of measuring the degree of susceptibility. The irritability of the cervix, instead of being increased by the catheter, is often considerably diminished by the careful and occasional introduction of a large instrument, more especially if assisted by regulated diet and alkaline saline medicines; whereas, if the operation be performed without such preparation, on a person enjoying high health, the combined efforts of the sudden distension of the cervix and prostate gland, the reduction of a hard stone into angular masses, that are propelled, at each time of voiding urine, into the prostatic part of the canal, and the natural susceptibility of the bladder, bring on a degree of inflammation that is with difficulty arrested. I shall have occasion hereafter to explain more particularly the danger to which the ma-

nipulation of the percussor exposes the neck of the bladder and prostate gland.

The presence of calculi in the kidney cannot always be ascertained before the operation is performed; nor does this seem to be important. If they are large, their existence is sufficiently indicated by the symptoms they occasion: and if small, they will descend down the ureter, without occasioning more than slight irritation of the system. One of the first patients on whom I operated had frequently been the subject of small phosphatic stones in the kidney; which, under exercise, would cause lumbar pains, and other signs premonitory of their descent into the bladder. On the day after that on which the stone was crushed for the first time, he experienced a severe rigor, with pain in the left loin: these were followed by a continued form of fever that lasted for two days, when he was relieved from the pain in the loin and ureter by a small stone escaping through the urethra, which could be distinguished among the fragments of the large calculus. Any person observing the patient under his attack would have thought him in imminent danger; but his surgeon, Mr. Wotton, who had often attended him in these attacks, knew their cause, and, with confidence, predicted a favourable termination as soon as the calculus entered the bladder. This gentleman had subsequently similar attacks during the sittings required for the complete destruction of his calculus, and rose from them as well as if nothing unusual had occurred. When the presence of a renal calculus is combined with disease of kidney, the case assumes an altered aspect, and one highly unfavourable for the operation.

(To be Continued.)

AN ADDRESS

DELIVERED TO THE MEMBERS OF THE
WORCESTERSHIRE
NATURAL HISTORY SOCIETY,
ON THE OPENING OF THE
WORCESTERSHIRE MUSEUM,
SEPTEMBER 15, 1836.
BY CHARLES HASTINGS, M.D. F.G.S.

(Concluded from page 273.)

We must not forget that, in all these investigations, Cuvier was greatly assisted by his appointment at the Jardin des

Plantes, which placed him in a situation where he was in the midst of those objects to which his life would have been devoted by inclination, and from the day of his appointment to the day of his death his labours were devoted to forming and completing the collections of which it can now boast, and which, when considered with regard to their arrangement as well as extent, may be pronounced unrivalled.

But great as were the labours of Cuvier in zoology, and brilliant as was the success that attended them, they cannot be compared in their results with those which arose from the devotion of his energies to the prosecution of another branch of natural history—geology. It has been well said that, in the hands of this distinguished man, natural history became adorned for the first time with the highest attributes of pure philosophy. To him we owe the most important of the laws which have regulated the distribution of the animal kingdom, and by the application of which we have been made to comprehend many of the mutations on the surface of our planet. He observes, “in my work on fossil remains I proposed to determine to what animals those fragments of bones should be assigned which occupy the superficial strata of the globe. This was an attempt to traverse the whole of a region of which as yet the first approaches were scarcely known. If we are interested in tracing out the nearly effaced vestiges of the early periods of our species, in so many nations utterly extinct, why should we not seek to discover, in the obscurity that envelopes that infancy of the earth, relics of revolutions long anterior to the existence of all nations? We admire that power of the human mind the exercise of which has enabled us to ascertain those motions of the planets which nature seemed for ever to have hid from us. Genius and science have soared beyond the limits of space. Observations developed by reason have detected the mechanism of the world. Would it not be some renown for man, in like manner, to penetrate beyond the limits of time, and to discover by research and reflexion the history of this world, and of a succession of events which preceded the birth of the human race?”

The celebrated work of Cuvier on fossil remains was undoubtedly the first that led to an accurate knowledge of the tertiary strata; indeed, from this work may be said to have proceeded that precision in the investigation of the relics of former worlds, which has placed geology on the

sure foundation of scientific induction. Cuvier, by the application of the rarest powers of observation and reflexion, and by an unequalled ingenuity, converted comparative anatomy into a sort of talisman for unfolding the wonders of the obscure contents, which lay for ages in the caverns of the earth. His researches on the fossil bones, as they now appear in the work before alluded to, form an epoch in the annals of geology, that yields to no part of its history in deep and durable interest; nor has the great author of this important discovery failed to consider it to be a source of wonder, as it was of pride to his own heart. "When," said he, "the sight of some bones of the bear and the elephants, twelve years ago, inspired me with the idea of applying the general laws of comparative anatomy to the reconstruction and the discovery of fossil species; when I began to perceive that these species were not perfectly represented by those of our day which resembled them most, I did not suspect that I was every day treading on a soil filled with remains more extraordinary than any I had yet seen; nor that I was destined to bring to light whole genera of animals unknown to the present world, and buried for incalculable ages at vast depths under the earth."

A highly talented reviewer, in alluding to this part of the labours of Cuvier, remarks that "to any one who indulges his solitary thoughts with the hope of enriching any part of the wide domain of natural history, an object eminently worthy of rational and contemplative beings, he would recommend the diligent perusal of the introductory essay of the great work in which the fossil remains are described; known to the English reader as a discourse on the Revolutions of the Globe. Cuvier is there beheld, if we may so say, advancing to his great task with a full consciousness of its extent, and of the additions which would be made by future inquirers even to his own discoveries; but at the same time with the confidence of one who enters on a region which, although obscure and encumbered, he has carefully prepared himself to explore. He designs from the first to show the relation between the history of fossil bones of terrestrial animals and the theory of the earth; to expose the principles by which the character of these bones was decided; to show how far the species of those animals to which they belonged differed from existing species; to ascertain the influences of time and of climate;

and thus to demonstrate that the differences must have been connected with extraordinary events as their causes. On these observations he builds up a new system of the ancient earth, not the offspring of fancy, but the result of philosophical induction, from facts carefully established, and which will bear the test of comparison with all the civil and religious records of man."

It does not always fall to the lot of great men to see the value of their labours and discoveries fully appreciated by the age in which they live; but Cuvier had the happiness to observe a just estimate formed of his exertions by all men of science in every part of the civilized world: we may also observe that he was highly rewarded by three successive rulers of the destinies of France, of which country he was finally made a peer. It has been imputed as a matter of blame, that so powerful a mind as Cuvier's should have so readily accommodated itself to the despotic Emperor, the weak and bigoted Bourbons, and the once liberal government of Louis Philippe. I am not, however, myself disposed to consider this circumstance as showing any want of fixed public principle, which casts a shade upon the memory of this great man, but rather to regard the honours bestowed upon him by a succession of princes, varying in their political views, as the homage paid to exalted genius, and should be proud to record in this enlightened country similar instances of marked distinction being conferred by our government upon the more favoured sons of science.

The grave has now closed upon Cuvier, and his voice is no more heard among men, but he yet speaks through his writings, which will long continue to be regarded as striking specimens of what a devoted zeal for science, when directed by superior intellectual endowments, can effect in the advancement of useful knowledge. In every part of the civilized world the name of Cuvier is revered, and every where disciples of this great man are to be found who are animated by similar zeal; and who, by following up the investigations which he has begun, are continually making fresh additions to the temple of science.

It is not my intention to attempt any detailed account of the many living labourers now employed with devoted energy in the advancement of Natural History. It may be sufficient to observe that at no former period in the history of the human race were so many men of

exalted intellect engaged in this pursuit, and never were their efforts so judiciously combined together as they are at present. We can boast in our own country of possessing great men, as naturalists, whose additions to science are so important as to place them in great estimation among men, and whose continued devotion to this object promises still further rewards to their investigations.

The study of the remains of extinct animals has been more especially pursued with great earnestness by Dr. Buckland, who has thrown much light on the history of the fossil mammalia of the most recent geological period, and whose patient, acute, and philosophical inductions from the bones found in caverns are a singular instance of the triumph of accurate knowledge over difficulties which would have prevented any ordinary mind from making out the conformation of these long extinct races of animals, and from, as it were, localizing these beings, long extinct and unknown, as having been inhabitants of the district where they were found.

The time would fail me to tell of Mantell, who, with the last mentioned writer, has brought, we may almost say, into renewed existence the monstrous Saurians; and who, by assiduous and never-wearying research among the oolites of Stonesfield and the Wealden limestone of Tilgate, has made known to us the *Magalosaurus* and *Iguanodon*:—of Sedgwick, whose forcible eloquence and sportive wit, combined with earnest zeal for the truths of revealed religion, has removed objections from timid minds who were disposed to view with suspicion the effects of the study of geology on the yet higher destinies of man:—Of Lyell, whose work on the Tertiary Formations constitutes a new era in geology, as it forces on the consideration of philosophers the necessity of a more careful consideration of the changes that are daily effected upon the surface of our earth by the causes which are in continual operation. The excellence of this production is of so high an order, that the author has been rewarded for these labours by the Council of the Royal Society, who have thought him worthy of receiving one of their royal medals; and whilst they decline to offer any opinion on the controverted positions contained in the principles of geology, they state the following as the grounds of their award:—

1. The comprehensive view the author
- No. 10.

has taken of his subject, and the philosophical spirit and dignity with which he has treated it.

2. The important service he has rendered to science by especially directing the attention of geologists to effects produced by existing causes.

3. His admirable description of many tertiary deposits, several of these descriptions being drawn from original observations.

Lastly, the new mode of investigating tertiary deposits, which his labours have greatly contributed to introduce, namely, that of determining the relative proportions of extinct and still existing species, with a view to discover the relative ages of distant and unconnected tertiary deposits.

Mr. De la Beche also, to whose pen and pencil Natural History has been for a series of years largely indebted, has lately published a small volume entitled "*Researches in Theoretical Geology*," the main tendency of which is to establish the importance and practicability of subjecting geological opinions to the tests of chemistry and natural philosophy. The author goes over much ground, keeping always the same direction, having apparently no other object in view than the acquisition and communication of sound knowledge, the detection and exposure of error, and the discovery and establishment of truth. Nor can I omit to mention the important labours of this author in conjunction with Mr. Conybeare. The admirable paper on the genus *Plesiosaurus*, in the fifth volume of the *Geological Transactions*, must be familiar to every geologist: and Mr. Conybeare's reconstruction of the fragments of the *Plesiosaurus Dolichodeirus* is a fine example of the sure grounds on which comparative anatomy enables us to proceed in these investigations, and places the name of this eminent geologist high among the successful followers of Cuvier in these pursuits.

All these, and many other labourers in the wide field of natural history, might detain me, with great propriety, whilst I unfolded to you their respective claims to our notice and regard. In abstaining, however, from any further account of these authors, I bend to the necessity of keeping within certain prescribed bounds this Address; but must at the same time call your attention to the important work of Mr. Murchison, which will soon appear, and which has so direct a reference to the natural history of our own district.

This distinguished and indefatigable geologist has for some years been employed in inquiring into the geological formation of the Upper Transition Rocks, in several counties in Wales, and in those of Salop, Hereford, Monmouth, and Worcester. To these rocks Mr. Murchison has now given the name of Silurian, and he has discovered in them a series of deposits replete with organic remains, which seem to him to afford a complete key to a large portion of the rock formations hitherto much neglected, while he has succeeded in collecting together a great number of organic remains which were previously unknown to naturalists. To these researches, interesting to all, we are more especially called upon to attend, as they relate to our own immediate vicinity, of which surely we should be anxious to collect every possible information.

If I fail to speak of Humboldt, it is because an essay rather than a paragraph should be devoted to set forth the various claims of this striking and enlightened traveller and natural historian upon the age in which he lives. It would be unpardonable in me not to allude to Agassiz, whose researches in fossil ichthyology promise to be rewarded by discoveries second only in importance to those of Cuvier. Among botanists, Brown and Hooker in our own country, and De Candolle in France, must take the highest station for their labours in systematic botany; while the researches of Lindley and Brogniart in the fossil department of that science, bid fair to assume an importance in the elucidation of the mineral strata scarcely inferior to that which attaches to the investigations of the fossil zoologist. I may also remark that none of the late achievements of philosophy seem more astonishing than the labours of Mr. Crosse of Taunton, who, previously wholly unknown, came prominently forward at the late meeting of the British Association at Bristol. His discoveries, in producing beautiful crystallizations and gems through the agency of electricity upon water impregnated with salts of lime, seem to invest the realities of experimental investigation with the magical enchantment of fiction and romance. These, with the results produced by Mr. Fox in artificially, by means of a blacking-pot and a few metals, imitating Nature's mode of forming metallic veins, promise to throw a more brilliant light upon the important operations that are continually in progress in the earth's dark bosom than our most sanguine anticipa-

tions could, a few short years ago, have imagined.

I would, then, finally ask you, what can you say to these things? Can you for one instant hesitate to admit that the wide field of natural history offers the most seductive attractions to the labourers in it? and that all institutions established for its cultivation claim your most earnest consideration and demand your best support? Indeed, with regard to our own promising society in the retrospective view of the last three years, we have whereof to glory. It has been said of the higher classes of the community in general in this country, that they are not only, from defects of education, slightly versed in scientific matters, but that they also show an indifference in assisting those who are desirous of becoming acquainted with the laws and structure of the universe they live in; but we glory that philosophy has with us made its way into the higher orders of the community, and that enlightened men of every degree, and sect, and party, have united together to accomplish the laudable objects at which we aim. We glory also that we have a noble patron, whose taste and capacity lead him to cultivate the higher departments of knowledge, and who, consequently, as belonging to the aristocracy of talent, has additional claims to our consideration, to those which he derives from his birth and station. We glory, also, that on the present occasion the sacred alliance which exists between the truths of nature and those of revealed religion, is evinced by the presence and presidency of our respected and venerable diocesan. We glory, likewise, that we have succeeded in engaging the female mind in our pursuits—a circumstance which has called forth from Archdeacon (now Bishop) Butler, in the address from which I have before quoted, the following interesting remarks:—"Natural history presents many charms to the cultivated female mind, considered as an innocent and an elegant pursuit, as combining information with amusement, and occupying without engrossing the mind; engaging it in agreeable study without withdrawing it from domestic duties; it has a thousand claims on female attention, particularly in those branches which relate to botany, entomology, and ornithology. It is therefore to be hoped that the ladies of Shropshire will follow the bright example set them by the neighbouring county of Worcester, in fostering the Society established there."

We glory, finally, that the management of the affairs of our Society has fallen into the hands of zealous and energetic men, who have taken advantage of the favourable influence of popular opinion, and have not only collected together many interesting objects in our museum, but have also been enabled, through the public liberality and munificence, to rear the splendid edifice in which I now utter these feeble and perishable words, and which promises to stand for ages as a memorial of those exertions by which so great a work has been accomplished. But I would yet impress upon you the conviction which I so strongly feel, that these advantages will be found of little avail without renewed exertion; for though the position we occupy is commanding, yet it will require great activity and vigilance to turn it to good account. And if I may venture still further to trespass upon you after having too long occupied your time and attention, I would conclude with expressing a desire, sincere and fervent, that harmony and good feeling may reign among us, that we may be secured from the baneful effects of little enmities and dissensions, and that no rivalry may be known within these walls, excepting that which arises from the animating ambition of attaining the great and noble ends to which this Institution is directed. Guided by these pure and wise councils, we may confidently anticipate that this Society will long continue to diffuse science and civilization, and to promote individual enjoyment and happiness, and the general good of the community at large.

Such were the aspiring hopes to which the founders of this Society clung in its nascent state, and as its more vigorous growth realizes these anticipations, they will experience a proud distinction in its onward progress. The two grand principles which true philosophy should instil into our minds are veneration for the Supreme Being and a desire to benefit mankind. It is to these grand objects that all our aspirations and all our desires should tend. It was to the establishment of these principles that the energetic mental powers of the great Reformer of modern philosophy were directed; and I may add, that in proportion as this Institution can succeed in implanting in the public mind this genuine, this Baconian, this Christian philosophy, in the same proportion will it diffuse the light of truth and dispel the clouds of darkness and of error which still hang upon the civilized world. Oh! that we may all

thus study the great Book of Nature, for then, indeed, the members of this Society, animated by the same spirit which inspired the immortal Milton, may with him triumphantly exclaim

How charming is Divine philosophy!
Not harsh and crabbed as dull fools suppose,
But musical as is Apollo's lute,
And a perpetual feast of nectar'd sweets,
Where no crude surfeit reigns.

The London Medical

AND

Surgical Journal.

Saturday, June 10th, 1837.

THE DUBLIN COLLEGE MONOPOLY.

We have, some short time since, received several communications from friends in Dublin, which want of space prevented our publishing before now: in postponing them we confess we also gratified our own feelings, for it is not without pain, that we should dwell upon, and give to the world the history of corruptions and abuses as they occur in Ireland, that country to which so warmly respond the best and dearest feelings of our heart. Still we have duties to perform, as public journalists, which must be fulfilled, and to which we must sacrifice every other less imperious sentiment. We have the satisfaction, however, of knowing that in performing a duty of this kind, painful though it be, we take the most effective steps to realize that grand and useful object, the establishment of effective medical institutions, founded on just and general principles, free from monopoly and corruption.

We have always dealt out praise, and with no niggard hand, when so doing was consistent with truth, when we had occasion to refer to the Irish College of Sur-

geons collectively, or to individuals influential in that corporation. We cannot then be charged with malevolence against either it or them; our sentiments on this head remain unaltered. This, however, does not nor should not make us blind to the vices, defects, and corruptions of a system, which, in candour, we must confess ought to be exploded, as quite unsuited and inadequate to the wants and requirements of improved modern times. The college in question, too, will find it their interest, to abandon the narrow basis of monopoly and the private gains of a few individuals (who, however respectable, can have no *just* claim to such distinction and pre-eminence), and to establish themselves on a broad and liberal foundation, that will recommend itself by its general utility and justice;—that is, if they wish to maintain their influence, nay, their very being, as an important public institution.

It is impossible to deny the charge brought against the Dublin College of Surgeons, that it is little or nothing else than a *private school*, with the power of granting degrees, placed in a lofty, pre-eminent position, supported at the public expense, to the great detriment of valuable public interests, propped up and supported by the most unjustifiable corruptions and monopoly, the professional appointments to which, not being open to the healthful principle of free public competition, but resting entirely with a very limited number of persons, who swallow up all the emoluments of influence, honour, and money, connected with it, and yield nothing, absolutely nothing, in return even to that limited community, upon which the unnatural and parasitic monster has been grafted.

To any one gifted with a particle of common sense, or in whom common sense has not been blinded by self-interest, it

must be evident, that, in these times, when we have on all sides such numbers of private schools, comprehending every excellence, no institution resting its claims upon such an unstable foundation, can hope for, or *merit* to survive the result of investigation and reform legislation;—it must be evident, also, that any system or policy constituted such as that we have just alluded to, must irritate the feelings, and insult the judgment of the excluded majority; and be at once, incompatible with justice and every sound principle, elements which are hourly bearing more and more essential parts of our social system, in all its details.

We are far from underrating the value of education, or of thinking such an important subject not amongst the very fittest to occupy the most serious attention of any of our colleges; we are far too from denying the passed services of the School in the Dublin College, services which were requisite during the total absence of all other opportunity of surgical education, services which we have been foremost to laud and defend; but who will not mourn, to see a royal corporation in the second city in the empire, vested with extensive powers and privileges, producing no other fruit, whatever, than crowns the unaided exertions of any half dozen of medical gentlemen in the empire, who unite together for the praiseworthy object of giving medical instruction in a private school? Who will not admit that such a puny result from such a complicated machine, is beyond doubt a most “lame and impotent conclusion?” Who will not, under such circumstances, be ready to confess there must “be something rotten in the state of *Denmark*?” Who will not acknowledge that here, there is a negative offence, a crime of omission of considerable magnitude, a treason against public interests, that

loudly demands correction and reform? But who will not be ready with the fullest and most hearty condemnation, when he learns that that treason, that negative offence, is maintained by a system of corruption and intrigue, that violates the commonest principles of justice and integrity; the offence is now no longer negative, but a positive crime of the blackest character, to leave which unremedied and unpunished, becomes an absolute neglect of public duty of the first importance, and a disregard of public interests of the most vital character.

Sentiments such as these have been long springing up among the members of the college, and there has long been a growing desire to abate or even annihilate the School, which (through the activity of those having a pecuniary interest in its existence) absorbs every other consideration and interest, and renders completely abortive, every attempt to promote the interests of science or of the surgical profession—in a word, to forward any object of public benefit. If this were a growing evil *within* the council chamber, what must be expected from the entrance to the membership of licentiates of all shades of opinion on medical politics, for, according to charter, every thing is done by a majority of voices in the Dublin College? Calculating thus, the School *proprietors*, for such they are, saw nothing but an early downfall from their (to the public) mischievous pre-eminence and pecuniary gains: they determined to anticipate this melancholy revolution, so mustering all their strength, they got passed a bye-law, which is perfectly illegal, and opposed to the entire spirit of their charter and constitution, to wit, a law making one-third black balls at the ballot for admission to the membership, fatal to the aspirant for that honour; in other words, giving to a minority of one-

third, the entire control over the future destinies of the corporation, in order to maintain a gross, and corrupt, and useless job, in which they themselves (the minority) are interested!

Such a law is evidently unjust; it has been pronounced by some of the first lawyers in Ireland perfectly illegal. It affects however the objects and intentions of the framers of it; it places entirely within the hands of the interested and factious school minority, the keys of the entrance portal of the college; no one is suffered to enter save by their permission, save by making terms with them; a power which we regret to be obliged to declare, they have used, and continue to use, without the slightest remorse or qualm of conscience, regardless of the violation of justice and of law, inseparable from such conduct, and of the outrageous stigma thereby attempted to be branded upon a man's most tender point, his reputation: it is painful to be obliged to put on record another of those moral associations.

The close-borough-condition of the Dublin College was now made apparent: there was scarcely an entrance into the membership for some years; it fell greatly in public estimation; in fact, those of the public who thought on the subject at all, were filled with indignation: meantime the school party rested satisfied while they counted the money in their purses. But the Poor Law Reform Bill is brought before Parliament, which threatens to cheapen the value of their licence, by admitting any other licence as qualifications for medical officer to the Irish charities.

Why must needs face a liberal, a reform government; how can they do so, while they labour under the damning defect of their being a corrupt close borough? This public impression must first be wiped out. They secretly prepare a list of half-a-score of licentiates, including

two of their own officers in the school, the sons of Mr. Colles—and all, the confidential apprentices of the school professors; they all pass the Rubicon of course, because the protégés and creatures of the interested school faction. One gentleman, however, a Mr. Baker, a professor in a private school, noted for its excellence and its reform principles, that of Mr. Ellis, in Peter Street, having got secret information of the intentions of the school faction, has the manliness and the independence to demand his just and undoubted right, by submitting to the ballot at the same time; and what is the result? He is branded as an outcast, unfit to associate with his professional brethren in the management of the College—and the profession! And for what? What breach of professional etiquette has he committed? Of what violation of kind, gentlemanly conduct, or morality, has he been guilty of, that he should be doomed to such extreme penalty? There is not a shadow of any such imputation or disqualification advanced against him: the majority of his professional brethren pronounce in his favour, but a minority of one-third, enter into a hellish conspiracy, because he is supposed to hold opinions different from theirs, but in unison with the majority of his medical brethren, because he is supposed to disapprove of their perverting a public corporation to a mere private school:—but this blow, beyond a doubt, will recoil with tenfold vengeance on the heads of the guilty faction themselves.

Were there no other argument than this, which strikes so wickedly against the first principles of common morality, it would be sufficient of itself to justify the sentiments and wishes of those, who aim at removing the School altogether, and thus making room for something else, which may not only not be injurious

to the best interests of science, the College, and the profession, but may be capable of positive public benefit.

THE KING'S HEALTH.

(From our Windsor Correspondent.)

Although the public mind has been, to a very considerable degree, tranquilised by a decided amendment having already taken place in His Majesty's health, it could not be expected that an attack of such alarming symptoms could be either yet permanently removed, or that such symptoms would not have been followed by a considerable degree of debility. The undisguised language which all around the King now appear unhesitatingly to make use of, in expressing the dangerous condition in which His Majesty was placed for some days, is of itself a proof of the accuracy of my former statements; and it is no longer attempted to be concealed that there has been, and still, though in a much less degree, continues, anasarca of the upper part of the trunk, as well as of the inferior extremities; and, though the mucous expectoration has greatly diminished, His Majesty is still afflicted with severe dyspnoea on the slightest motion. The great diminution of the anasarcous swelling, has been attributed to the exhibition of *SENEKA* or *SENEGA*, a remedy which in the case of the King has most fortunately produced the most beneficial effects, under the watchful eye and judicious guidance of the President of the Royal College of Physicians. Whilst, therefore, a gladdening improvement has taken place in His Majesty's health, and every laudable endeavour made by the King himself, as by the Court, to impress on the public mind the complete re-establishment of His Majesty's health, it is impossible not to view but with the greatest anxiety His Majesty's condition,

as long as any vestige of disease continues, the ailment being of that description which unfortunately, more particularly in the different branches of the Royal Family, is so apt to recur.

Some amusing reports have gone abroad regarding some most absurd and fallacious conclusions, as to the state of the thoracic viscera, which one of the medical attendants had drawn from the use of the stethoscope; and had not Sir Henry's acute diagnostic powers rendered the line of practice quite indisputable, in all probability His Majesty's condition would have been very different from what I rejoice to state it now is.

THE ANATOMIST.

MUSCLES.

MUSCLES OF BACK OF LEG.

Superficial Layer.

Gastrocnemius. *O.* internal head, upper and back part of internal condyle of femur, and oblique ridge above it; *external head*, from above external condyle. *I.* lower and back part of os calcis.

Plantaris. *O.* back part of femur above external condyle, and posterior ligament of knee. *I.* posterior part of os calcis.

Soleus. *O.* external head, from back part of head and superior third of fibula; *internal head*, from middle third of tibia, unites with gastrocnemius to form tendo Achillis. *I.* lower and back part of os calcis.

Popliteus. *O.* depression on outer condyle of femur. *I.* flat triangular surface, occupying the superior posterior fifth of tibia.

Flexor digitorum perforans. *O.* posterior flat surface of tibia, from below popliteus to within three inches of ankle, fascia, and intermuscular septa. *I.* last phalanges of four lesser toes.

Tibialis posticus. *O.* posterior internal part of fibula, upper part of tibia, and nearly whole-length of interosseous ligament. *I.* inferior and internal tuberosity on os naviculare, internal cuneiform and cuboid bones, and second and third metatarsal bones.

Flexor pollicis longus. *O.* two inferior thirds of fibula. *I.* last phalanx of great toe.

MUSCLES OF FOOT.

First Layer.

Abductor pollicis. *O.* lower and inner part of os calcis, internal annular ligament, plantar aponeurosis, and internal intermuscular septum. *I.* internal sesamoid, and internal side of base of first phalanx of great toe.

Flexor digitorum brevis perforatus. *O.* inferior and internal part of os calcis, internal annular ligament, plantar aponeurosis, and intermuscular septa. *I.* second phalanges of four lesser toes.

Abductor minimi digiti. *O.* outer side of os calcis, ligament extending from os calcis to outer side of fifth metatarsal bone, plantar fascia, external intermuscular septum, and base of fifth metatarsal bone. *I.* outer side of base of first phalanx of little toe.

Second Layer.

Musculus accessorius. *O.* inferior and internal part of os calcis. *I.* outer part of tendon of flexor digitorum longus.

Lumbricales. *O.* tendons of flexor digitorum longus. *I.* internal side of first phalanges of four lesser toes.

Third Layer.

Flexor pollicis brevis. *O.* lower and anterior part of os calcis and external cuneiform bone. *I.* sesamoid bones, beneath first phalanx of great toe.

Adductor pollicis. *O.* calceo-cuboid ligament and base of second and third metatarsal bones. *I.* external sesamoid bone.

Transversalis pedis. *O.* anterior extremities of four external metatarsal bones. *I.* external sesamoid bone of great toe.

Flexor brevis minimi digiti. *O.* cuboid and fifth metatarsal bones, and sheath of tendon of peronæus longus. *I.* inner side of base of first phalanx of little toe.

Fourth Layer.

Seven interossei muscles. Three on sole of foot, and four upon its dorsum.

Inferiores, vel interossei interni.

1st. *adductor medii digiti.* *O.* inner side of third metatarsal bone. *I.* base of first phalanx of fourth toe.

2nd. *adductor quarti digiti.* *O.* inner side of fourth metatarsal bone. *I.* inner side of first phalanx of third toe.

3rd. *adductor minimi digiti*. O. fifth metatarsal bone. I. inner side of base of first phalanx of little toe.

Superiores, vel interossei externi.

1st. O. intersal side of second metatarsal bone and outer side of first. I. inner side of base of first phalanx of second toe.

2nd. O. opposite sides of second and third metatarsal bones. I. outer side of first phalanx of second toe.

3rd. O. opposite sides of third and fourth metatarsal bones. I. outer side of first phalanx of middle toe.

4th. O. opposite sides of fourth and fifth metatarsal bones. I. outer side of first phalanx of fourth toe.

THE MUSCLES OF THE ORBIT.

1. *Levator palpebræ superioris*. O. upper edge of foramen opticum. I. superior border of tarsal cartilage.

2. *Obliquus superior*. O. foramen opticum. I. sclerotic coat between superior and external rectus.

3. *Obliquus inferior*. O. orbital edge of superior maxillary bone. I. sclerotic coat between it and external rectus muscle.

4. *Rectus superior*.

5. *Rectus inferior*.

6. *Rectus internus*.

7. *Rectus internus*.

[All arise round optic foramen, the external rectus being also attached to margin of sphenoidal fissure, and they are inserted about a quarter of an inch behind cornea.]

MUSCLES OF INTERNAL EAR.

Stapedius. O. within pyramid. I. neck of stapes.

Tensor tympani. O. canal in petrous portion of temporal bone, above Eustachian tube. I. short process below neck of malleus.

Laxator tympani. O. spinous process of sphenoid bone and Eustachian tube. I. processes gracilis of malleus.

BRAIN AND ITS MEMBRANES.

Dura Mater.

A firm dense fibrous membrane, adhering by its outer surface to the bones of the cranium, its inner surface being intimately connected with the arachnoid membrane. It defends the brain, acts as an internal periosteum to the bones of the skull, forms the sinuses, and sends envelopes upon the several nerves as they pass through the cranial holes. It sends off the following processes.

Falx Cerebri commences narrow at crista galli, and arches backwards between the lobes of the cerebrum, becoming deeper until it meets the tentorium, with which process it is continuous on either side. Its convex edge corresponds to the median groove of the os frontis, the sagittal edges of the parietal bones and the upper half of the perpendicular ridge of the occipital bone. The great longitudinal sinus is in its upper edge, and the lesser longitudinal sinus in its inferior free concave edge.

Tentorium extends in a horizontal manner above the cerebellum and below the posterior lobes of the cerebrum. Its convex edges contains the lateral sinuses and correspond to the transverse ridges of the occipital bone, the inferior posterior angles of the parietal bones, the superior angles of the petrous portion of the temporal bones, and to the clinoid processes of the sphenoid bone.

Falx cerebelli is attached to the lower half of the perpendicular ridge of the occipital bone, and extends between the lobes of the cerebellum towards the foramen magnum.

Sphenoidal folds are attached to the lesser wings of the sphenoid bone.

SINUSES.

Great longitudinal sinus, of a triangular form, extends along the convex margin of the falx cerebri. It commences by a small vein in the foramen cæcum, and increasing in size as it proceeds backwards pours its blood into the torcular Herophili. Its interior is crossed by small bands called *chordæ Willisii*, and presents the openings of the veins which course upon the upper surface of the cerebral hemispheres, and a number of small whitish granules called *glandule Pacchioni mediae*. Upon the outer surface of the upper wall of the sinus, between it and the cranium, are situated the *glandule Pacchioni externae*.

Inferior longitudinal sinus is very small, runs along the concave edge of the falx cerebri, and terminates in the straight sinus.

Straight sinus passes from the termination of the inferior longitudinal sinus downwards and backwards, receiving the blood of the venæ Galeni and empties itself into the torcular Herophili.

Lateral sinuses, each corresponds to the transverse groove in the occipital bone, the groove in the posterior inferior angle of the parietal bone, the mastoid fossa of the temporal bone, and the

groove in the occipital bone in either side of the foramen magnum; when it passes through the foramen lacerum posterius and terminates in the jugular vein.

Torcular Herophili corresponds to the centre of the crucial spine of the occipital bone, six sinuses communicate with it, viz.: the two lateral, the great longitudinal, the straight and the two occipital.

Cavernous sinuses, each extends from the anterior clinoid process, to the petrous portion of the occipital bone; and upon being cut into presents a cellular appearance. The internal carotid artery the sixth nerve, and branches of the sympathetic nerve are found within each, but separated from the blood by the reflected venous lining membrane. In the outer wall of each run the third and fourth nerves, and the first branch of the fifth; the sinus of either side presents the openings of the ophthalmic vein, of the two petrosal sinuses, and of the circular sinus.

Circular sinus surrounds the pituitary body and is formed of an anterior and posterior transverse vein which extends from one cavernous sinus to the other.

Superior petrosal sinuses, each passes from the cavernous sinus along the upper angle of the petrous portion of the temporal bone, to the lateral sinus.

Inferior petrosal sinuses, each passes from the cavernous sinus downwards and backwards, along the line of contact of the petrosal portion of the temporal bone, and the occipital to the lateral sinus.

Transverse sinus crosses the cuneiform process of the occipital bone, and connects the inferior petrosal sinuses.

Occipital sinuses, two in number, are contained in the falx cerebelli, and open into the torcular Herophili.

TUNICA ARACHNOIDEA.

Belongs to the class of serous membranes, is spread over the surface of the brain without penetrating between its convolutions, and is reflected upon the dura mater, in those situations where the nerves and veins pierce this fibrous membrane; thus, after the manner of all serous membranes, forming a shut sac, and consisting of a parietal and a visceral layer. It also gains access to the interior of the brain by the arachnoid canal, and lines the free surfaces of the ventricles.

PIA MATER.

The vascular covering of the brain lines its entire surface, dipping between its convolutions and sending numerous blood-vessels into its substance, it is inti-

mately connected to the arachnoid membrane by its outer surface, except at the base and sulci of brain; and entering the ventricles by the great transverse fissure at the base of the brain, presents the choroid plexuses and the choroid membrane.

THE BRAIN.

The brain is subdivided into three portions, viz.: the cerebrum, the cerebellum, and the medulla oblongata.

THE CEREBRUM.

This is the largest of the three divisions, is of an oval form and is divided into two equal portions called hemispheres, by a fissure which extends along the median line upon its upper surface, and contains the falx cerebri and the antennæ of the corpus collosum. At the base of the brain the cerebrum is also divided at each extremity by the medium fissure, but in the centre both hemispheres are united.

Hemispheres, right and left, are convex superiorly and externally, and flat towards each other, where they correspond the falx.

Lobes. Each hemisphere is divided into three lobes upon its under surface; the anterior, which is the smallest, rests upon the roof of the orbit and presents a groove for the lodgement of the olfactory nerve; the middle, prominent and convex, lies in the middle fossa, in the base of the cranium; and the posterior rests upon the tentorium.

Fissura Sylvii separates the anterior from the middle lobe, and corresponds to the lesser wing of the sphenoid bone and its fold of dura mater. The cerebral roof of this fissure is pierced by small arteries, branches of the middle cerebral artery.

Convolution, or gyri, are eminences longitudinal and rounded, but directed in various ways upon the surface of each hemisphere.

Sulci are the fissures which separate the convolutions from each other, over which the arachnoid membrane passes, but into which the pia mater dips.

Cineritious substance of brain is of a yellowish grey colour, from three to four lines in thickness, soft and vascular, and for the most part situated upon the outer surface of the brain. It is however found in striæ and masses in the interior of the brain, and surrounded by the medullary substance. In some situations its colour assumes a dark hue, as is seen when a section of the crus cerebri is made.

Medullary substance, white-elastic and fibrous, forms the greater part of the brain.

Centrum ovale minus, an oval mass of medullary substance surrounded by cineritious substance, and rendered apparent by making a section of each hemisphere within a few lines of the corpus callosum.

Centrum ovale magnum, the large oval mass of medullary structure, which is rendered apparent by slicing both hemispheres on a level with the corpus callosum.

Corpus callosum, unites the hemispheres to each other, is about three inches in length and presents upon its upper surface the *raphe*, which corresponds to the anterior cerebral arteries, and from which, on either side, pass the connecting transverse fibres of the hemispheres, called *lineæ transversæ*. It unites by its posterior extremity with the fornix and the hippocampus, major and minor; its anterior extremity being curved upon itself and continuous with the optic commissure and tuber cinereum at the base of the brain.

Septum Lucidum descends from the raphe of the corpus callosum to the fornix, separating the lateral ventricles from each other. It consists of four layers, two of which are cineritious, and two medullary; the medullary layers having in general a cavity between them called the fifth ventricle: its form is triangular, the apex corresponding to the union of the corpus callosum and the fornix, the base anterior, corresponding to the curved portion of the corpus callosum.

Lateral ventricles, each consists of a body and three cornua, the body corresponding to the centre of each cerebral hemisphere, the cornua proceeding, one to each lobe. The bodies of the ventricles are separated from each other by the septum lucidum.

Corpora striata, two pear-shaped bodies, their large bulbous extremities being contained in the anterior cornua of the lateral ventricles, their narrow stalk-like extremities being directed backwards into the bodies of the ventricles; they are cineritious on their surface, but when cut into present alternating stræ of cineritious and medullary matter, and hence their name.

Optic thalami, two large bodies placed behind and between the corpora striata, each presents upon its inferior surface two tubercles, called *corpora geniculata*. Towards the median line the optic thalami are flat and united to each other by

a soft cineritious structure, called *commissura mollis*; upon their external surface they are white, but their interior is grey.

Tænia Semicircularis.

Tænia, a narrow medullary band situated in the groove between the optic thalamus and corpus striatum of either side.

Fornix, placed horizontally beneath the septum lucidum and corpus callosum, and composed of medullary structure, arches above the third ventricle, and lies upon the velum interpositum and choroid plexus. It commences by its two posterior crura, one of which lies in the inferior cornu of either lateral ventricle; these unite in the median line and form what is called the *body* of the fornix, which passes forwards and terminates in the *anterior crura*: finally, the *anterior crura* descends to the base of the brain, where they terminate in the corpora mammillaria.

The Lyra, is the appearance presented upon the under surface by some slight lines and depressions which correspond to the vessels of the velum interpositum.

Choroid plexus. The fold of pia mater which lies upon the optic thalamus, and which entered the body of the lateral ventricle by the inferior cornu; the choroid plexus of either side passes forwards and inwards, and both unite in the foramen commune arterius.

Velum interpositum, lying underneath the fornix, unites the choroid plexuses of either side; it is composed of arachnoid membrane and pia mater, and contains in its centre the *venæ Galeni*.

Venæ Galeni, contained in the velum interpositum, pass from before backwards and terminate in the straight sinus. These veins return the blood from the choroid plexuses and from the parts within the ventricles.

Pineal gland, a small conical cineritious body containing in general sandy matter. It is placed upon the corpora quadrigemina and is connected with the brain by a small transverse medullary band and two peduncles.

Hippocampus minor, an oval eminence in the posterior cornu of the lateral ventricle; medullary externally, and cineritious in its interior.

Hippocampus major, a similar eminence to the minor but larger, and placed in the inferior cornu of the lateral ventricle.

Pes hippocampi, the tuberculated appearance which the extremity of the hippocampus major presents.

Tænia hippocampi, another name for the posterior crura of the fornix, which are attached to the hippocampus major of either side by their convex margins, their concave edges being free.

Corpus denticulatum, a cineritious serrated line in the inferior cornu of the lateral ventricle, and which is exposed upon removing the tænia hippocampi, beneath which it lies.

Third ventricle, a deep fissure between the optic thalami, exposed by separating these bodies. It is bounded anteriorly by the descending crura of the fornix and the anterior commissure, posteriorly by the posterior commissure and the tubercula quadrigemina, laterally by the optic thalami: its floor corresponds to the locus perforatus and tuber-cinereum, and it is covered in by the velum interpositum and fornix.

MONOPOLY OF THE DUBLIN COLLEGE OF SURGEONS.

The following *precious* document has just fallen into our hands. It appears to have been drawn up about the time the Medical Education Committee was appointed, but is now again circulated with the view of influencing the government and legislature to maintain the Dublin College of Surgeons in its monopoly with respect to County Infirmaries in Ireland. In next week's number of the Journal we shall call the attention of the profession, throughout Great Britain and Ireland, to this statement. We think the London College of Surgeons can scarcely overlook the imputations on them.

Statement of the Royal College of Surgeons in Ireland, respecting the appointment of Surgeons to County Infirmaries.

By an act passed in the 5th and 6th Geo. 3, it is enacted, that "no person shall be capable of being elected (as surgeon to a county infirmary) who shall not have served a regular apprenticeship of five years to a surgeon, and have likewise undergone an examination before the surgeon-general, the visiting surgeon, the two assistant surgeons, and the resident surgeon of Stephen's Hospital, and the five senior surgeons of Mercer's Hospital, and shall produce a certificate from said examiners, that he hath served an apprenticeship of five years to a surgeon, and hath undergone a proper examination as aforesaid, and is in all respects qualified

to be a surgeon to the said infirmary or hospital."

The enactment of this provision in 1765, twenty years before the incorporation of the Royal College of Surgeons, proves, incontestably, that it was made solely to secure to the sick poor proper surgical assistance, and to prevent unqualified persons from becoming connected with county infirmaries; and it is to be recollected that there were at this time several practitioners educated in Edinburgh and on the Continent, settled in different parts of Ireland.

By the 36th Geo. 3, it is enacted that "no person shall be capable of being elected surgeon to a county infirmary or hospital, who shall not previously have obtained letters testimonial of his qualification, under the seal of the Royal College of Surgeons in Ireland."

The policy of transferring the duty of examining the infirmary surgeons from the old board to the more responsible body, the College of Surgeons, was obvious; but this was not done for twelve years after the formation of the College in 1784, and, consequently, after the College had given proofs of its efficacy, and that it could be with safety intrusted with so important a duty.

By the 54th Geo. 3, the surgeon of a county infirmary shall lay before the grand jury his letters testimonial, thus confirming the measure of the Irish parliament, after eighteen years of its efficacy.

In 1818, the sense of the Imperial Parliament was again taken on the question, the London College of Surgeons having framed a bill "to regulate the practice of surgery throughout the united kingdom," into which a clause was introduced to remove the barrier raised by the Irish Parliament to protect the poor in the infirmaries, and to cancel the trust reposed in the Irish college. This clause became the subject of debate in the House of Commons, and was successfully resisted, especially by Mr. Peel, who, from information acquired on the spot, was enabled to form a correct opinion on the subject.

It appears, therefore, that during sixty-eight years this matter was four times submitted to discussion; twice in the Irish Parliament, and twice in the Imperial—each successive inquiry and enactment proving the policy and justice of the original provisions.

From the most superficial view of the above enactments, it is obvious that they

were not made for the purpose of aggrandising the College of Surgeons, or of extending to it any undue patronage or monopoly.

That the laws above recited have had the most salutary effect as regards the county infirmaries, no one practically acquainted with their operation can for a moment deny. But this is not the only advantage resulting from their enactment. The selection and adoption of the diploma of the Royal College of Surgeons, Ireland, by the legislature, as the best test of the fitness of the surgeon to discharge the important duties of medical superintendent of an infirmary co-operating with the strict system of education and rigid examinations enjoined by the college, has had the effect of raising this Irish institution to the highest place in public estimation. These two great advantages the legislature is called on to sacrifice, in order to enable every holder of a surgical degree in Ireland, to participate in the professional distinction and emoluments derived from the county infirmaries, however low that diploma may be held in public estimation, or however easily obtained.

If any surgeon in Ireland wishes to qualify himself for the appointment of county infirmaries, he can do so in one week, by producing evidence that he has been for six years engaged in the study and practice of his profession, and by passing a public examination—men advanced in years, and enjoying extensive practice, have done so.

If the legislature considered it necessary, in 1765, 1796, and 1814, to institute a strict scrutiny into the qualifications of candidates for the appointment of surgeons to county infirmaries, it is surely still more necessary, at the present moment, when so many are practising surgery in Ireland under the authority of diplomas granted by colleges totally ignorant of the wants of Ireland in this particular, and little interested in the welfare of the country generally.

It has been argued that the infirmaries would be served by affording the governors an opportunity of selecting surgeons from the largest possible numbers; but when it is known that there are 386 graduates of the Irish college, from which a selection may be made, this argument has little weight.

There is one topic which cannot be left untouched in this discussion, however displeasing it may be to those affected by it, and however repugnant to national pride or prejudices; it is the question, whether

diplomas in surgery, granted by the colleges of other countries, and especially by the College of Surgeons in London, should be considered as genuine and valuable tests of qualification as that of the Irish college.

It is to be presumed that the London College, acquainted with the practice of the profession in England, as regards education, have judiciously and effectually modelled and adopted their system to that practice; but unacquainted with the wants of the people, the practices of the profession, and the state of society in Ireland, they have totally failed in their attempts to supply the necessities of this country in that particular. The fact cannot be concealed, that the inadequate exercises, the short period of practical study, and the brief examination upon which the London College have granted diplomas to Irish students, has been attended with the most mischievous consequences to Ireland.

The efforts of the Irish College to enforce a proper system of surgical education in Ireland, pursuant to the provisions of their charter, have been greatly weakened by the opportunities afforded to students to obtain diplomas on easier terms elsewhere. The best friends of Ireland should therefore, in place of diminishing the influence of the Irish College of Surgeons, strengthen their hands by additional powers, and oppose every obstacle to the interference of other colleges with surgical education in this country.

If the London College claim a right to intermeddle in the regulation of surgical education in Ireland, by virtue of their charter, such claim must be firmly resisted. No such object was ever thought of for one moment, or contemplated in their incorporation.

It has been urged that all the hospitals of England are open to Irish surgeons, and that, therefore, this privilege should be reciprocal. This objection to the laws recited above, would be more specious than just. There is no special legislative provision which renders the members of the Irish College ineligible to English hospitals; but as the local or domestic regulations or practice of these institutions restricts the situation to those who have served apprenticeships in them, the Irish surgeons are virtually excluded.

Until the legislature shall be induced to consider the subject of medical and surgical education an object of national importance, and to compel the different

colleges to adopt an equally rigid, protracted, and laborious system of education, this question of reciprocity cannot be entertained. To compel, by any indirect laws, the Irish College to lower the standard of its system of education to that of any other college, would be too flagrant an act of injustice.

MEDICAL CHARITIES. (IRELAND.)

A BILL FOR THE BETTER REGULATION OF
HOSPITALS, DISPENSARIES, AND OTHER
MEDICAL CHARITIES IN IRELAND.

PREPARED AND BROUGHT IN BY LORD
MORPETH, MR. ATTORNEY GENERAL FOR
IRELAND, MR. FITZSTEPHEN FRENCH,
AND MR. WILLIAM O'BRIAN.

WHEREAS it is expedient to make provision for the better regulation of the several hospitals, dispensaries, asylums, and other medical charities now existing, or which may hereafter be required in Ireland; Be it therefore enacted, by the King's most excellent Majesty, by and with the advice and consent of the Lords spiritual and temporal, and Commons, in this present Parliament assembled, and by the authority of the same, That from and after the first day of October, one thousand eight hundred and thirty-seven, the parts of the several Acts hereinafter mentioned shall cease, determine and be repealed; that is to say, so much of an Act passed in the Parliament of Ireland in the fifth and sixth years of the reign of King George the Third, intituled, "An Act for erecting and establishing Public Infirmaries or Hospitals in this Kingdom," as relates to the qualification of surgeons to be elected for such infirmary or hospital, and to the presenting of money by the grand juries for support of same; and so much of an Act passed in the Parliament of Ireland in the seventh and eighth years of the reign of King George the Third, intituled, "An Act to amend an Act made in the last Session of Parliament for the erecting and establishing Public Infirmaries or Hospitals in this Kingdom," as relates to the qualification of Physicians to be elected to County Infirmaries in Ireland; and so much of an Act passed in the Parliament of Ireland in the thirty-sixth year of the reign of King George the Third, intituled, "An Act for the further Regu-

lation of Public Infirmaries or Hospitals," as relates to the qualification of surgeons, to be elected to county infirmaries in Ireland; and so much of an Act passed in the forty-fifth year of the reign of King George the Third, intituled, "An Act to amend and render more effectual an Act made in the Parliament of Ireland in the fifth year of his present Majesty, intituled, 'An Act for erecting and establishing Public Infirmaries or Hospitals in this Kingdom,'" and of an Act passed in the forty-seventh year of the reign of King George the Third, intituled, "An Act to amend an Act made in the last Session of Parliament, for regulating and providing for the Relief of the Poor, and the Management of Infirmaries and Hospitals in Ireland," and of an act passed in the forty-seventh year of the reign of King George the Third, intituled, "An Act to amend an Act made in the Parliament of Ireland in the fifth year of his present Majesty's reign, for erecting and establishing Public Infirmaries or Hospitals in Ireland," as relates to the presentment of money by grand juries for infirmaries or hospitals; and of so much of an Act passed in the fifty-fourth year of the reign of King George the Third, intituled, "An Act to amend several Acts for erecting or establishing Public Infirmaries or Hospitals in Ireland," as relates to the qualifications of surgeons elected for county infirmaries or hospitals in Ireland; and so much of an Act passed in the fifty-eighth year of the reign of King George the Third, intituled, "An Act to establish Fever Hospitals, and to make other Regulations for Relief of the suffering Poor, and for preventing the increase of infectious Fevers in Ireland;" and of an Act passed in the third year of the reign of King George the Fourth, intituled, "An Act to amend an Act passed in the fifty-eighth year of the reign of his late Majesty King George the Third, for establishing Fever Hospitals, and for making other Regulations for Relief of the suffering Poor, and for preventing the increase of infectious Fevers in Ireland;" and of an Act passed in the third and fourth years of King William the Fourth, intituled, "An Act to amend the Laws relating to Grand Juries in Ireland;" and of an Act passed in the third and fourth years of King William the Fourth, intituled, "An Act to explain and amend the Provisions of certain Acts for the erecting and establishing Public Infirmaries, Hospitals and Dispensaries in Ireland," as relates to the

presentment of money, by grand juries for hospitals and dispensaries in Ireland; and so much of an act passed in the first and second years of the reign of King George the Fourth, intituled, "An Act to make more effectual Provision for the Establishment of Asylums for the Lunatic Poor, and for the custody of Insane Persons charged with Offences in Ireland;" and of an Act passed in the sixth year of the reign of King George the Fourth, intituled "An Act to amend an Act of the first and second years of his present Majesty, for the Establishment of Asylums for the Lunatic Poor in Ireland;" and of an Act passed in the seventh year of the reign of King George the Fourth, intituled, "An Act for the further Amendment of an Act of the first and second years of his present Majesty, for the Establishment of Asylums for the Lunatic Poor in Ireland;" and of an Act passed in the sixth and seventh years of the reign of his present Majesty, intituled, "An Act to consolidate and amend the Laws relating to the Presentment of Public Money by Grand Juries in Ireland," as relates to the repayment of advances of money from the consolidated fund to be made to lunatic asylums in Ireland after the first day of October one thousand eight hundred and thirty-seven.

And be it enacted, That it shall and may be lawful to and for the lord lieutenant or other chief governor or governors for Ireland for the time being to nominate and appoint four fit and proper persons, being physicians or surgeons duly qualified by the provisions of this Act, to be inspectors of hospitals, infirmaries, asylums, dispensaries, and other medical institutions in Ireland, removable at the will and pleasure of the lord lieutenant, or other chief governor or governors of Ireland for the time being; and such four persons shall perform all the duties prescribed for the medical inspectors as directed by this Act.

And be it enacted, That each of the said inspectors shall receive such salary as the lord lieutenant or other chief governor or governors of Ireland shall appoint, not exceeding to each the sum of hundred pounds in the year, together with such allowance for travelling expenses as the said lord lieutenant or other chief governor or governors shall appoint; which salary and allowance shall be payable in quarterly payments out of the consolidated fund of the United Kingdom of Great Britain and Ireland.

And be it enacted, That such inspectors

shall not themselves be attached to or in anywise connected with any hospital, infirmary, asylum, dispensary, school of surgery, pharmacy, or other medical institution whatever, or derive any pecuniary emolument from private practice as a physician or surgeon, or from the performance of any duty imposed upon them by this Act, other than the salary and allowance hereinbefore provided.

And be it enacted, That the said inspectors may meet and sit from time to time, in such place or places as they shall find most convenient, with or without adjournment, and shall have an office in the city of Dublin, to be called "The Medical Charity Office;" and that all acts, matters, and things which the said inspectors are by this Act authorized to do or execute, may be done and executed by any two or more of them; and that they shall and may, with the consent and approbation of the lord lieutenant or other chief governor or governors, employ such clerks and officers as they may find necessary; and that all and every the persons so employed in any such capacity may from time to time be dismissed at the pleasure of the said inspectors, and any other person or persons, with the like consent and approbation, appointed in his or their stead, and shall make such general regulations respecting the medical care of patients deriving medical aid from infirmaries, fever hospitals, asylums, dispensaries, and other medical institutions in Ireland, and such other rules and regulations for the general management of such institutions as they shall think proper, and shall have power from time to time to alter such regulations.

And be it enacted, That from and after the passing of this Act, the said inspectors shall be inspectors of all district lunatic asylums supported by presentments in Ireland, established under any Acts now in force; and such inspectors shall have all the same powers relating to the inspection of such lunatic asylums as by any Acts now in force relating to such lunatic asylums are given to the inspectors general of prisons, who shall cease to have any authority to inspect or visit said lunatic asylums.

And be it enacted, That every hospital, asylum, dispensary, and other medical charity in Ireland, shall be visited twice at the least in every year by one or more of the said inspectors, who shall report upon the state of every such institution to the Medical Charity Office in Dublin.

And be it enacted, That the poor law

commissioners for the time being, acting in the execution of an Act of the present session of Parliament, intituled, "An Act for the more effectual Relief of the Poor in Ireland," shall hereafter exercise a general superintendence over all infirmaries, hospitals, dispensaries, asylums, and other medical charities throughout Ireland, and over the said medical inspectors appointed under the provisions of this Act.

And be it enacted, That before the twentieth day of January, one thousand eight hundred and thirty-eight, and so in every succeeding year before the twentieth day of January in each year, the governors, directors, or committees of the several hospitals, infirmaries, asylums, dispensaries, and other medical charities in Ireland, or the treasurer or other proper officer of every such institution respectively, shall yearly and every year make out and deliver or transmit to the Medical Charity Office in Dublin, a return containing a statement and accounts of all the funds intrusted to the governors, directors, or committees of every such institution respectively, for the benefit of every such institution, and of the application of such funds for the year ending on the thirty-first day of December preceding such twentieth day of January, with the balances of the debts and credits, and of the whole funds of every such institution respectively, on such thirty-first day of December; and also the number of patients or persons received into and sent out of every such institution respectively during such preceding year, and the number of persons who have received advice or medical aid therein during such year, and the number of patients remaining therein at the time of such return, and the number and names of the physicians, surgeons, officers, servants, and other persons employed in or about the management of every such institution respectively, together with an estimate of the amount which will probably be required for the maintenance throughout the year of such institutions respectively, in which estimate shall be stated in detail all expenses that will probably be incurred, whether for buildings, repairs, provisions, medicines, salaries, or other expenses incidental to such institutions, and shall transmit such estimate to the said Medical Charity Office, with all such other matters and things relating to the management, revenue, and expenditure of every such asylum respectively, as shall from time to time be required by the said medical inspectors for the full disclosure of the state

of every such institution respectively; and all the said returns, statements, and accounts shall be signed by the secretary, treasurer, or chief officer for the time being of every such institution respectively, and shall be confirmed as just and true statements by the signature of three governors, directors, or committee of every such institution respectively.

And be it enacted, That a half-yearly return of the state of disease in each district, and of the number of patients to whom medical aid has been administered in each of the Institutions aforesaid, shall be transmitted to the said Medical Charity Office, by the medical attendants attached to each such institution; and a general abstract and summary of such returns, together with a general abstract and summary of the expenditure upon each class of the medical institutions aforesaid shall be laid before Parliament in each year during its sitting.

And be it enacted, That the medical inspectors shall have and they are hereby authorized and empowered to use and exercise all such powers for the obtaining of the accounts, statements and returns by this Act required to be made, relating to the said institutions, and in the exercising and stating of the accounts of the receipt and expenditure, and of the debts and credits of every such institution respectively as are given to or vested in the commissioners of accounts under and by virtue of an Act made in the fifty-second year of the reign of his late Majesty George the Third, intituled, "An Act to provide for the speedy and regular examination and audit of the public accounts of Ireland," with respect to the matters and things required to be done by the said commissioners of accounts under the said Act; and all and every persons and person shall be subject and liable to such pains and penalties for any disobedience to any orders of the said inspectors in the execution of this act as are inflicted or imposed by the said recited Act on persons disobeying the orders of the said commissioners under the said recited Act.

And be it enacted, That from and after the passing of this Act it shall and may be lawful for the Lord High Treasurer or the commissioners of His Majesty's Treasury of the United Kingdom of Great Britain and Ireland, from time to time to order and direct that any sum or sums of money shall be advanced and issued and paid out of the growing produce of the said consolidated fund to such person or persons as shall be named in

any such order, or into the Bank of Ireland in the name or names of any such person or persons, to be from time to time paid and applied, under the direction of the medical inspectors, for the purpose of carrying on, maintaining and supporting any such institution from time to time in any district in Ireland, to such amount and at such times, and in such manner and proportions, and upon such estimates, and under such rules, regulations, terms, and conditions, and with such penalties for breach of such rules, regulations, terms and conditions, as to the Lord Lieutenant or other chief governor or governors of Ireland shall seem best suited for promoting the beneficial purposes of any such institution according to the provisions of this Act.

And be it enacted, That the elections of all physicians or surgeons to any hospital, infirmary, asylum, dispensary or other medical institution in Ireland, shall be from amongst the members or licentiates of one of the royal colleges of physicians or surgeons, or chartered universities in Great Britain and Ireland.

And be it enacted, That it shall and may be lawful to and for the medical inspectors, by and with the consent and approbation of the Lord Lieutenant or other chief governor or governors of Ireland, wherever the public convenience may require such a proceeding, to alter the hospital or dispensary districts now existing, and to make new districts either by uniting together, dividing or otherwise altering the present districts, or in such other manner as the said inspectors shall think proper.

(To be continued.)

SCHOOL FOR MEDICAL EDUCATION AT MADRAS.

We have been informed that this school is to be distinguished from that at Calcutta, which alone is to be designated a College. This we think impolitic for two reasons; first, that the term college and title of principal or professor entail no expense on the government, while they command great importance with the generality of mankind, who look generally more to the names of things than even to their intrinsic value; secondly, this distinction would infer that the sources of information and means of instruction are to be inferior at the sister presidency to those afforded at the city of palaces; which ought not to be the case. We hear that the students at Madras are

equally forward with those at Calcutta, and consequently the latter should not be more favoured than the former. We are glad to hear that the foundation of a Medical College is in contemplation at Ceylon. What are our brethren about at Bombay and in the north western provinces?

THE MILITARY FUND.

Several questions of importance have recently been discussed by the Directors as regards the pecuniary condition of this fund, the result of which has been that they have very properly resolved on sending instruction to the committee now sitting in London to submit the fund to three competent actuaries, in order to arrange it on equitable and permanent principles. We are confident this information will secure general approbation.

WANT OF MEANS PREVENTS MANY FROM SUBSCRIBING TO THE MEDICAL FUND.

Is a fact just brought to our notice: we were ourselves fully aware of this as will be seen by our articles on the condition of the medical service; but it has come so prominently before us that it is our intention to propose that the term one year now allowed to pay up arrears should extend to two years; and we have no doubt the committee will accede to the proposition.

IS THE BOON DESIRABLE WITHOUT THE FUND?

Far different is the case if we may compare the question with that now agitated by the army, viz. that the officers cannot avail themselves of the boon unless the permission to purchase one is conceded. The principle of purchase and that of the fund are the same, and the question is indisputable that the seniors will not retire without some tempting inducement to do so.

Indian Medical Journal, No. 9.

NOTICE TO CORRESPONDENT.

J. T. S.—The elastic corsets of Shoolbred and Renwick will be found highly useful in the case mentioned. They are far superior to all other articles of the kind.

All communications and works for review to be forwarded, (carriage paid) to Dr. RYAN, 4, Charlotte-street, Bloomsbury-square.

Fat—Adhesions and Ossifications—Hydatids—Worms—Rudolphi's Classification—Tubercles—Miliary, Crude, and Mature Tubercles—Opinions of Galen, Loyd, Portal, Baillie, Heberden, and Baron—Encephaloid tumours—Three kinds of Cancer—Pott on Fungus Hæmatodes—Melanosis—Cause of the Black Colour—Opinions of Cullen and Carswell—Scirrhus—Its membranous Crura—Open Cancer, or Carcinoma—Carmichael, on the Independent Vitality of Cancer.

III. Proximate Causes.—These consist of alterations in either the structure or functions of parts, and are therefore divided into organic and functional. The organic proximate causes may be divided into four classes:—1. Inflammation and Fever; 2. Depositions; 3. Gangrene; 4. Displacements. Depositions are of four kinds:—1. Natural Tissues in excess; 2. Preternatural Tissues; 3. Natural Fluids in excess; 4. Preternatural Fluids. The displacement of organs includes:—1. Intus-susception; 2. Hernia; 3. Prolapsus; 4. Extra-uterine conceptions; 5. Miscarriages; 6. Fractures; 7. Dislocations. The Functional Proximate Causes may be divided into three classes:—1. Spasms, and other examples of increased action; 2. Convulsions and other examples of irregular action; 3. Palsies, and other examples of diminished action.

1. Inflammation and Fever.—Inflammation consists in diminished action of the capillary blood-vessels; in consequence of which the blood which accumulates in them is not propelled onwards. The French say it consists in diminished action; but they look only at the first stage of inflammation, which precedes the collapse, and before the "rubor, tumor, calor, and dolor" are present. We make the cold stage of fever part of the disease, but not the cold stage of inflammation,

which they do ; and hence they are more consistent than we. Increased secretion is the third stage, both of fever and inflammation.

I think Wilson Philip is right in considering fever a diffused inflammation of the surface. The old writers thought that inflammation was a spontaneous flux of the four fluids we have already mentioned,—blood, yellow bile, black bile, and mucus. Hall said it was a spasm of the capillaries, which tended to keep them full ; but Hoffman and Cullen thought the spasm tended to empty them, and to fill the large vessels. The arteries of an inflamed part, however, are as full as the veins ; whereas, according to this doctrine, they ought to be empty. Hunter said there was an increased elasticity of the arteries in inflammation, tending to dilate and not to contract them. Bellengeri introduced the new doctrine, that inflammation is the result of diminished action following increased action. Boerhaave thought there was a preternatural lentor of the blood (*spissitudo*), combined with an error loci. Hastings and Wilson Philip applied stimuli to the web of a frog's foot. It was first blanched, from the constriction of the blood-vessels ; and then the vessels became expanded, and the circulation retarded. Thomson says that the circulation in inflamed parts, is sometimes quicker and at other times slower. The quantity of blood which is transmitted, probably remains unaltered, although its celerity is lessened from the expansion of the vessels.

Broussais says that subacute inflammation is seated in the capillary veins, and the origins of the lymphatics. Tubercles and morbid growths, he thinks belong to this variety of inflammation. Common inflammation he looks upon as seated in the capillaries which carry red blood (the arteries). This view is adopted by Jenner, Adams and Baron. The proximate cause of inflammation and fever may be either organic or functional ; but the change being molecular, may not be detected after death.

The stages of fever are three. 1. Constriction ; 2. Relaxation ; 3. Reaction. Armstrong likewise makes three, but differently named,—1. Oppression ; 2. Excitement ; 3. Collapse. This arrangement, however, refers to the system generally ; whereas the former relates to the skin. It is said by many, that there are no idiopathic fevers, fever being always a local disease, and the skin being inflamed by sympathy. Broussais says that local

disease is always gastro-enteritis ; and that even in pneumonia the inflammation of the lungs causes gastro-enteritis, and the latter fever ; so that the gastro-enteritis is a sort of half-way house. This view originated with Beddoes and Hunter, and was followed by Abernethy. Marcus and Clutterbuck point to the brain, as invariably the seat of the local affection in fever ; others, as Currie, to the liver ; and others to the spleen. Mills says it is the weakest organ, whichever that may be ; and this is probably the true state of the case. Cullen said that, in fever, there was at first debility, and then the *vis medicatrix naturæ* excited a spasm of the capillaries to throw more blood on the heart, and to excite it to action. The modern improved notions are as follows:—1. All fevers are from excitement. 2. The causes of fever act differently in different cases, so that there is no idiopathic fever. 3. In all fevers bleeding may be resorted to in the first stage, for by diminishing excitement the subsequent collapse will be lessened. There cannot, therefore, be any essential debility in the first stage. Since 1816 the treatment of fever has been very much improved by the writings of Jackson, Sutton, Armstrong, Bateman, Pritchard, Percival, Duncan, Graham, Welsh, and others.

Inflammation is of five kinds. 1. Phlegmonous ; 2. Erythematic ; 3. Rheumatic ; 4. Scrofulous ; 5. Scirrhus. The two latter occur only in morbid structures ; so that the healthy body is liable only to the three first. The erythematic occurs only in the skin, the mucous membranes, and the internal coat of the veins ; the rheumatic occurs in fibrous and muscular parts ; and all the rest are liable to the phlegmonous. Scrofulous inflammation takes place in melanosis, encephaloid humours, and phthisis ; but not in healthy tissues. Scirrhus inflammation is not that by which scirrhus matter is deposited (which was probably from healthy inflammation), but it is that inflammation which takes place in consequence of some injury done to the scirrus so deposited. The morbid depositions of inflammation differ according to temperament, and this tendency to a particular kind of inflammation is called a diathesis.

The following are the characters of the different kinds of inflammation:—1. Erythematic. Irregularly diffused ; disappears on pressure ; has no pointing ; is attended by a burning pain ; goes on to desquamation or bullæ. 2. Rheumatic.

Not attended by redness, and not by much heat; pain chiefly on motion; frequent metastasis. 3. Phlegmonous pain; pulsation and suppuration. 4. Scrofulous, or strumous. Of a pinkish colour; attended by little or no heat; pain slight; suppuration not healthy; presenting a thin humour with flocculi; the discharge afterwards becoming viscid and albuminous. 5. Scirrhus. Of a purple or lead colour; hard and knotted with rugæ; not much heat; pain lancinating and not increased by pressure; produces suppuration,—open carcinoma. The discharge is a yellow sanies; corrosive, and of a very bad odour.

Inflammatory is distinguished from spasmodic pain, by the different effect of pressure. Spasmodic pain is from the contracted muscles pressing on the nerves; and pressure, by preventing muscular contraction, relieves the pain. In the first place you substitute a general pressure for an interstitial one; in the other you add to the interstitial pressure.

Inflammation may terminate either in resolution, increased deposition, or gangrene. Resolution is often attended by critical fluxes, of which the five following are the principal:—1. Perspiration; 2. Nasal Mucus; 3. Diarrhœa; 4. Hæmorrhage; 5. Urine. Inflammation is diminished action, or irritation in the vessels; recovery is increased irritation, which becomes, by sympathy, a stimulus to other parts, which parts become first irritated, and then collapsed. If this secondary collapse continues, it becomes a metastasis; but if quickly followed by irritation and secretion, a flux is established; so that the latter is not the cause, but the effect of the inflammation terminating. Inflammations have a tendency to be intermittent, as is seen in gout, ophthalmia, erysipelas, odontalgia, and cynanche tonsillaris. It used to be said that only nervous diseases are intermittent; but all diseases are nervous.

2. *Depositions of Natural Tissues in excess.*—Increased deposition is probably from increased secretion of coagulable lymph, and not from effusion, even in hæmorrhage and dropsy. Coagulable lymph has probably within itself the materials of its own organization; thus resembling a seed. This is a more prevalent opinion than that the vessels are acquired from the surrounding parts.

The deposited matters are of various kinds:—1. Induration is an increase of density in a part, without an increase of space. 2. Hypertrophy is an increase of

space, without an increase of density. It may be either concentric or excentric. 3. Stricture is a new growth, from coagulable lymph, either on the smooth side of a mucous membrane, or in the cellular tissue on the rough side. Bridle or ring strictures are produced in the former way, and occur in all the mucous membranes. 4. Polypi occur only in parts liable to erythematic inflammation; the skin, mucous membranes, and nervous tissue. A true polypus is covered with mucous membrane; has a peduncle; is never laminated; and has evident vessels, especially at the peduncle. A false polypus is the contrary of all this. An aneurism is the best example of the latter. 5. Teeth are found generally in conjunction with hair and fat, in the ovaries, testicles, uterus, bladder, and sometimes the stomach. They correspond with the teeth in the jaws of those animals in which they are found; nor can the formation of the teeth in the jaws be explained any more than that of teeth elsewhere. Bremser says they are transmuted hydatids.

Serous membranes, when inflamed, pour out their secretion in increased quantity, and form adhesions by cords which become organized; for they are the first to be attacked in subsequent inflammations, as is seen in pleuritis. Indeed, it is a general rule in the animal economy, that the parts last formed are first attacked. The wisdom-teeth, for instance, are first lost. Hence Sherwin says, that one way to get rid of polypus of the heart, is to give the patient scurvy.

Ossifications occur in all parts of the body, coagulable lymph being first deposited. Morbid ossifications are not true bone, not being organized. They are only calculi.

3. *Depositions of Preternatural Tissues.*

—These include hydatids, worms, tubercles, encephaloid tumours, melanoses, scirrhi, and culculi of various kinds.

(1.) *Hydatids.*—Hydatids and tubercles probably result from different degrees of the same inflammation. The presence of hydatids may excite an inflammation leading to the deposit of tuberculous matter. Bremser says that although hydatids may become degenerated or transmuted into teeth, tubercles cannot: for the latter, he says are organized, and one form of organism cannot be changed into another.

(2.) *Worms.*—These and hydatids are the simplest forms of the deposition of preternatural tissues. They are divided into four families, each of which is again

subdivided, so as to make twelve different kinds in the whole :—

Cystica (proper Hydatids).

Cysticercus Cellulosus.

Echinococcus Humanus.

Nematodea (Cylindrical Worms).

Hamularia Subcompressa.

Ascaris Lumbricoides.

Trichocephalus Dispar.

Oxyuris Vermicularis.

Strongylus Gigas.

Filaria Medinensis.

Trématoda (Intermediate Worms).

Dystoma Hepaticum.

Polystoma Pinguicula.

Cestoidea (Tape Worms).

Bothriocephalus Latus.

Tænia Solium.

In this enumeration we have followed Rudolphi's nomenclature. We shall say a few words of each in turn :—1. *Cysticercus*, or bladder-tailed hydatid. This, which is not common, sometimes occurs in the choroid plexus and the muscles. 2. *Echinococcus humanus*, a name applied by Rudolphi to the *acephalocysts*, which are found everywhere throughout the body, except in the intestinal canal. 3. The *Hamularia subcompressa* is found in the bronchial glands. 4. The *Ascaris lumbricoides*, or the lumbricus as it is sometimes called, is a long round worm, which inhabits the stomach and small intestines. It differs from the garden-worm (*Lumbricus terrestris*) in being of a pinkish colour, without hairs on its body, having at the mouth three vesicles, which are probably suckers, and a tapering tail, with the anus situated at some distance from its extremity. The garden, or common earth worm, has but one vesicle at the mouth, is of a brown colour, is furnished with hairs, and has a flat tail, with the anus at its extremity. 5. *Trichocephalus dispar*, or *trichuris vulgaris*, a long thread worm. This is the most common of all the worms, and infests the *caput cæcum coli*. 6. The *Oxyuris vermicularis*, or *ascaris vermicularis*, occurs in the rectum. 7. The *Strongylus Gigas* is the only animal found in the urinary passages. Many others come from them, but they are introduced *ab extra*. 8. The *Filaria medinensis*, *dracunculus*, *vermiculus capillaris*, guinea worm, or hair-worm, has its locality in muscular parts. It is very long and slender. 9. The *Dystoma hepaticum* (*fasciola hepatica*, or fluke) is found in the gall-ducts. 10. The *Polystoma* (from *πολυς* and *δομα*) is so called from the numerous mouths with which it is furnished—it has six at one end and

one at the other. Its specific name is *pinguicula*, because it was found embedded in fat, in an ovarian tumour. 11. The *Bothriocephalus latus*, or *tænia osculis superficialibus*, is the *broad* tape-worm, and it inhabits the large intestines. 12. The *Tænia solium*, or *tænia osculis Marginalibus*, is the *long* tape-worm. It is found, like the last, in the large intestines.

Linnæus thought the cyst which surrounds false structures in the body, was a living animal, and gave it the name of *acephalocystis*. Linnæus thought that worms were introduced into the body in the form of ova; and that the differences between them and worms formed out of the body were caused by the peculiarity of their habitat. But we find nothing resembling them out of the body; their differences are such as their habitat could not occasion; they will not live out of the body; they ought, if introduced *ab extra*, to be found only in the intestinal canal, yet they exist in the *fœtus* and sucking infant Pallas and others have said, that they descend in the blood from father to son. But their existence in the blood is generally denied, and if they really were there, they should be of the same description in all parts of the body. Lock, Rudolphi, and Bremser maintain that they are secreted by inflammation, the symptoms of which precede them, instead of being produced by them, as is generally supposed. In children, for instance, all possible symptoms are set down to worms, because these symptoms attend gastroenteritis, which produces the worms.

(3.) *Tubercles*.—These morbid productions pass through three stages—miliary, crude, and mature. 1. Miliary tubercles are small hard pellucid granulations, of a greyish colour. 2. Crude tubercles are larger than miliary; yellow, opaque and cheesy. 3. Mature tubercles begin to soften in the centre, and become ulcers.

Hippocrates thought they were inspissated mucus; Loyd, that they were the same as the inspissated bodies found in the lacunæ of mucous follicles; and Galen, that they were the cicatrices of the ruptured vessels, coming after hæmoptysis. Portal, Baillie, Heberden, and Broussais think they are enlarged lymphatic glands. Baron maintains they are hydatids, for hydatids and tubercles are often found together; and hydatids are sometimes surrounded by tubercular matter. Tubercles are chiefly found in the lungs, and never in any other part of the body, without being found in the lungs at the same time.

(4.) *Encephaloid Tumours*.—Fungus *Hæmatodes*, which is another name for Encephaloid Tumour, is the first of the three kinds of cancer, the other two being Melanosis and Scirrhus. Fungus *Hæmatodes* was first well-described by Pott. In the beginning of its course it is of a pale colour, irregular on its surface, and fringed with blood. In the second stage it becomes larger and redder, and in the third it forms a ragged unhealthy ulcer, which easily bleeds, and pours out sanies at every touch. It is found in the integuments, the eye, the testicle, the mamma, and the brain. It is sometimes encysted, and is said to be the only kind of cancer which has evident vessels.

(5.) *Melanosis*.—In the first state, melanosis is of a hardish consistence and black colour; in the second it becomes softer, and in the third pours out a black liquor and becomes a black cancer. Cullen and Carsewell state a fluid is poured out at first, which becomes indurated and excites inflammation around. Others say its origin is analogous to that of tubercles. It is found in almost all organs of the body. One case of general melanosis occurred at the Infirmary of Edinburgh, and another case is related by Fordington. The black colour of this tumour is considered to be owing, either to a change in the blood, or to the deposition of new matter, much charged with carbon. A melanotic tumour is sometimes organized, and furnished with a peduncle.

(6.) *Scirrhus*.—In the latent stage it is hard and cartilaginous, and of a yellow colour, with membranous crura internally, shooting in all directions. Between these septa the spaces are filled up with greenish coloured vesicles. In the second, or crude stage, it becomes ragged, nodulated and painful; though not tender on being handled. In the third stage it becomes open cancer, or carcinoma.

Carmichael thinks cancers are living animals. Baron says they are transmuted hydatis. Meckel says they always take their origin in sebaceous and mucous follicles; and certainly they are most common where these follicles are most abundant.

OLEUM EMPYREUMATICUM STRAMONII.
—This oil is distilled, not from the leaves, but from the woody part of the plant: its odour is less unpleasant, and resembles tar. The liquid, which comes over with it, is acid.

LECTURES ON SURGERY.

By JOHN HUNTER, F.R.S.

OF SUSCEPTIBILITY OF IMPRESSIONS; OF STIMULI; OF DISPOSITIONS OF THE BODY; OF HABIT AND CUSTOM.

Of Stimuli—When carried too far they become Irritants—Of Dispositions of the Body—Much less understood than those of the Mind—In Health arising from Impression—In Disease independent of it—Of Dispositions in the Mind—Their ultimate Effects are on the Body—Both compared with the Actions of Machines—Of the Memory of Impressions—In the Body as well as the Mind—Example—Effects of Repetition of Natural Actions Habit and Custom—Of Custom—Diminished Effects from repetition of Impression—Increased Effects.

Every species of matter, whether inanimate or animate, is capable of impressions, and the effects of the impression are according to the nature of the impression and the part impressed. A piece of dough receives impressions, but seems chiefly passive, not having the power of reacting, and making but little resistance. Elastic bodies receive impressions, which they restore in a contrary direction, producing ultimately various effects, which I have said are the soul or life of mechanism.

In animal bodies the effects of impressions are more various and complicated than in inanimate matter, because the most simple animal is more varied and complicated in its susceptibilities of impression, and of course more complicated in its dispositions for action.

In inanimate matter there are no actions within itself excepting the disposition to restate itself, as in elasticity; therefore impressions are not rising up within itself, in consequence of its own actions, as in animals, so as to produce consequent dispositions and actions, unless we could conceive that chemical and fermentative operations were of this kind. But animal matter having internal actions, which are producing impressions to action in the parts impressed; and, secondly, this kind of matter is capable of being acted upon or impressed by common inanimate matter, in both which cases the impression will be according to their nature and to that of the part affected.

When a man is so affected as to feel within himself that he cannot live, which is very common, it arises from the mind

being made acquainted with the state of the body; the living powers are become weak, inactive, &c., and the nerves are communicating the intelligence. Accordingly, their actions are expressive of the extinction of life going on, and the action of the brain is expressive of such actions of the nerves; and as death is a something we know takes place, and this sensation of ours, is not such as we feel in health, we conclude that we cannot live, and we are often not deceived. This effect is often so quick that it may exceed the sensation of it, or at least may hardly afford us time to communicate these sensations to others.

The internal susceptibilities, with the consequent impressions and dispositions, are, first, of want, and, second, of repletion; and all the other internal operations of the machine arise naturally from these two, especially repletion, or digestion, circulation, respiration, secretion, the intercourse of the sexes, &c. But the first movement of these actions appears to require the impression of external matter, the powers of digestion being excited by food being thrown into the stomach, in consequence of which circulation, respiration, secretion, &c., all follow, arising out of the internal operations of the machine; all which have nothing to do with the sensitive, but are wholly dependent on the living principle. The desire of food, or susceptibility of the stomach to digest it, arises not from external objects, but from its own organization.

The second kind, susceptibility of external impressions, chiefly affects the sensitive principle, but may also affect the living principle, as in medicines. These are called stimuli; and when both principles are affected they may be said to have the management of the machine.

Impression, or stimulus, produces a disposition to act, or rather action, may or may not take place. But all impressions, either on the living or sensitive principle, are not stimuli; some go beyond stimulus, and become irritants; and other impressions are from their nature not stimulants, but produce a disagreeable impression either to the mind or body, and are also irritants.

Stimuli.—An animal, I have observed, is susceptible of impressions; which impressions, I shall now observe, are to become causes either of immediate or remote disposition to action, either in the part impressed, or by some other sympathy. These impressions, which excite or increase the disposition, are called stimuli;

therefore we may say that a part is stimulated, or such an application, substance, or object is a stimulus; and a part either readily increased in action by impression, or brought into action, we say is very susceptible of stimuli. I could wish we had some one word expressive of this condition of the part stimulated, as stimuable, and also of the stimulus, as stimulative, to answer to irritable, sensitive, &c.

An impression which becomes a stimulus by sympathy may have been carried so far as to have been an irritator of the part to which it was applied, as a mote in the eye irritates the tunica conjunctiva, which irritation acts only as a stimulus to the lachrymal gland, for this gland can only act by sympathy. The power of a stimulus must be according to the nature of the stimulus and of the part jointly, for as almost every part of the body has a peculiarity in its mode of action, every part must have its peculiar stimulus.

An animal is so constructed as to have its parts susceptible of stimuli at one time and not at another. An animal has a power of improving its parts so as to make them susceptible of such stimuli as are adapted to the disposition of the parts: for instance, an animal improves all those parts peculiar to the sexes. When those parts are perfect, which is called the age of puberty, they stimulate the mind and various other parts connected with that, giving rise to the passion of love, or the appetite of lust.

On the other hand, want becomes the cause of impression: a part becomes susceptible of such want, so that the ultimate effect or stimulus is completely produced, and an appetite arising from such stimulus takes place. Thus, the stomach when empty is susceptible of the stimulus of hunger. This kind of stimulus may be carried so far as to excite a diseased action, and must then be considered as an irritant.

Of Dispositions of the Body.—It may be difficult to define a disposition of the body, but that the body has dispositions is undeniable; and without knowing this, and therefore coming at or endeavouring to come at the knowledge of these dispositions of the body, a man must be a very confined surgeon in his practice. But the term disposition is more commonly applied to mind than to body. In the mind it is more easily comprehended, because the mind has the power of investigating its own feelings or dispositions, also the power of communicating them, by means of the body, to the minds of others,

so as to be understood or felt by those minds.

Every man has felt perhaps every disposition that can arise in the human mind, and is therefore perfectly sensible of those dispositions when they occur in others. But in the present inquiry the mind has no intelligence of the feelings or dispositions of the body, and is obliged to compare the effects of the one with those of the other, and where they are similar to suppose that the causes are also similar.

A disposition either in the mind or body, when in health, always arises from some impression; but as both mind and body are capable of seemingly spontaneous actions, there may arise from diseased dispositions in both, producing madness in one case and strong disease in the other.

As disposition may arise in consequence of some impression, it is capable of being destroyed by a counter impression, which in disease is the method of cure that will be called specific. Many dispositions wear themselves out, or are such as the body or part cannot go on with.

A disposition is different from a visible action, yet it is possible it may be itself an action. If we compare the actions of the body with those of the mind (which is comparing from analogy, and perhaps the only mode we have), we shall gain a pretty good notion of them.

A disposition of the mind, then, certainly arises either from some action of the brain, or a certain position of the parts of the brain takes place, giving them an inclination to produce action. But this action, or the position which produces the inclination to action, we know nothing of; it is only a sensation of the mind, or rather a consciousness of the mind of such inclination, which sensation, or consciousness, is different from the sensation of the brain, arising from other actions of this viscus: and also knowing that such action of the brain as produces such sensation in the mind, is endeavouring to set other parts of the body into action, which may be called voluntary, or rather actions in voluntary parts; and that when such actions of the brain have taken place, such dispositions of the brain are lost; I say, knowing so much, we may, from analogy, form some idea of bodily dispositions. But the dispositions of the body appear to differ in this respect from those of the brain, that in the brain there is only the disposition, the ultimate or consequent action taking

place in the body. But this is, perhaps, because we are not much acquainted with the immediate effects of the disposition in the brain, being led away by the visible actions which take place in the body.

To explain this let us suppose that I have an impression made upon my body in such a manner that my sensitive principle is sensible of it; if, for instance, a man gives me a knock on the head that makes me angry, I form a disposition from this of resenting it; that disposition in my mind produces an action in my brain which forms a peculiar state of the mind, which is anger. If it was an action of some other kind, it might be affection or gratitude. The brain can do nothing by way of retaliation, whether it be gratitude or revenge which directs, but to set parts of the body to work. Having received a blow on my head, the disposition in my brain to produce the action of revenge sets my hands to work to give my enemy another blow, and then the disposition is at an end. So that whenever the action has taken place, the disposition is gone. The ultimate effect is made sensible to us, and we are apt to imagine that it is the immediate act of the disposition of the brain; but it is only that the immediate action which took place in the brain made other parts of the body act secondarily, so that three actions are necessary to the ultimate effect; but they are not all three actions of the brain. There is, 1st, the action which produces the disposition; 2nd, the action of the nerves in consequence of the disposition; 3rd, the action of the voluntary muscles in consequence of the action in the nerves: but only the two first actions belong to the brain.

Let us see how far this disposition and consequent action of the brain correspond with the dispositions of the body and the actions arising in consequence of these dispositions.

If on any part of an animal an impression is made, a disposition is formed suitable to that impression, which is the first; and an action in the same part suitable to that disposition may take place, which is the second, and is the ultimate; but if a sympathetic action takes place, it becomes somewhat similar to the ultimate effect on the body, arising from a disposition in the brain.

We may, with great propriety, compare the disposition and action of either the brain or the body with the disposition or action of an elastic body. An elastic body, when acted on (which is similar to

an impression made on the body), acquires a disposition or inclination, which, if allowed, will produce action in all parts of the elastic body, which destroys the disposition. The disposition to action, and the action, are two very different things in themselves, even in the elastic body: when the elastic body has performed its action, it remains at rest until acted upon again; but it always requires action to destroy disposition.

We must make a material distinction between a disposition and an action in diseases, for what will cure an action will have no effect on a disposition.

Every machine is composed of very different parts, yet all tend to some ultimate effect. Every machine, whether natural, as an animal body, or constructed by art, however simple it may be, yet is always composed of more parts than one: and it must be observed, that no two parts have the same action, although all are tending, even in the most complicated, to produce some one ultimate effect.

For instance, some machines of art are intended for the division of time, as a clock, which may be so simple as to perform that effect by one wheel, the effect being expressed by an index. Some, again, are much more complicated, all the parts, however, being employed to the same ultimate effect, namely, the movement of this index, which expresses the ultimate effect; and the different parts composing the clock may be called organs.

So it is with natural machines; some animals are so simple as to have apparently but one operation, and that is support, and these may be called one organ. Others are complicated, being composed of different parts, whose actions and effects appear complete in themselves, as the action of a kidney, a liver, &c.; yet all combine to produce an ultimate effect in the machine, namely, the preservation and continuance of the species.

To produce the ultimate effect in any machine, there must be a succession of actions; one naturally arising out of another, each part taking on the action peculiar to itself; the preceding action being always the stimulus to the next succeeding one; and thus the parts go on acting in regular succession until the ultimate effect is produced, and then the whole is at rest until stimulated into action again. In some parts this is almost immediately, as in the heart, organs of respiration, &c., thus, when the heart has thrown out its blood, it has done its business; when we

inspire and expire, the organs of respiration have done their business, but there is a necessity for the recurrence of the operation again, and so immediately that it seems almost constant. But in others there is a greater distance of time before the action is renewed, as in hunger, evacuation of the feces, urine, &c.

An animal body so constructed gives us an idea of perfection, for as each part has its particular appointment, one should naturally expect equality or powers suitable to these appointments would be found through the whole. But this certainly is not the case, at least in the more complicated animals, whatever it may be in the more imperfect or simple. We find this in the more perfect, where life depends for support on the action of some one part, as the heart; also where many actions of the animal depend on the powers of another part, as the voluntary actions on the brain; and not only the simple voluntary actions of the body depend on this viscus, but their real strength depends on it, for whenever the power of the brain is taken off, they waste; and this wasting does not arise from the brain supplying these parts with nourishment, and that being now cut off they lose their future support, but it arises from want of necessity to keep these parts in a state fit for action when action cannot take place, because the will cannot now stimulate them to action; and the same thing takes place in a proportionate degree when a joint is simply rendered, either wholly or in part, unfit for motion, where no injury has been done to the nerves. Hence it must appear, that as the power of support is in one part of the machine, and the power of many actions in another part of the machine, it is possible that all parts of the body may not be equally served by the first, namely, the heart; nor equally influenced by the second, the brain; and we do find that the more distant parts from these sources of power are the weakest. This, perhaps, is better illustrated in disease than by any actions of health. We may just observe, that all the vital parts are near the one, and all the acute sensations near the other. In disease we see a mortification arising in the extremities more than in the other parts, and more especially if the person is tall, so that the heart is not capable of propelling the support of life to those distant parts in such a state of the constitution.

How far the blood may lose its power

of nourishment before it reaches the extremities, I will not say. If our acute sensations are near to the brain, it is reasonable to suppose that proximity of parts adds to the power of the nerves in communicating sensation; if so, it is reasonable to suppose that proximity of parts will also add to that power which the brain has over actions of voluntary parts by means of the nerves.

On Habit and Custom.—Memory, or recollection of first impressions, has, I believe, principally been applied to, or supposed to be an attribute of the mind only; but we know that every part endowed with life is susceptible of impressions, and also that they are capable of running into the same action without the immediate impressions being repeated. Habits arise from this principle of repetition of, or becoming accustomed to, any impression, and the same thing exactly takes place in the mind. The memory of the body is of much shorter duration than that of the mind. The mind not only goes more readily into action the second time of an impression, though a considerable distance of time has taken place since it went into the same action before, but seems to take up the action with more ease, from merely collateral causes, from a recollection of the similarity, or often without any possible recollection whatever, as if the actions, in consequence of the former impression, were taking place in the brain again. This does not appear to be so much the case with the memory of the body, for this only arises from immediate impression, but goes into action a second time more readily than at first. Possibly, however, the action arising from the first impression may be repeated from some collateral or similar impression to the first; if so, it comes very near to that of the mind, though not so strong.

A gentleman rubbed in mercurial ointment for the reduction of two buboes; he had only used it a few times when it affected his constitution so much that he was obliged to leave it off: he became feverish, the fever being of the hectic kind, with a small quick pulse, debility, loss of appetite, no sleep, and night sweats. He took the bark, with James's powder. As the effects of the mercury went off, and his buboes were advancing, it was necessary to have recourse to mercury again: he now rubbed in a considerable quantity without its having the least effect on his constitution or mouth; but the buboes spreading made me order

it to be left off again, and they were opened. He had recourse to the ointment a third time without its producing any disagreeable effect. The buboes took on a healing disposition, but then became stationary. I ordered him to leave off the ointment, to go to the sea, and bathe, and then they began again to heal. In about three weeks it was thought necessary to rub in again: when he began, it almost immediately affected his mouth very violently; he left it off till his mouth was a little better, when he began for the fifth time, and it had not so much effect, and he was able to pursue the mercury. Now in this case he had lost the mercurial habit during the time he was at the sea, the parts had forgotten the mercury altogether, and the mercury coming on such a state of constitution, produced the same effect as it would have done if he had not taken mercury. So that the body had, as it were, lost the remembrance of the effect of the mercury on it in so short a time; but the mind would not have lost it.

Custom is with me the negative of habit; by custom comes an insensibility to impression, the impression diminishing although the cause is the same, and the parts becoming more and more at rest; whereas from habit there comes an increased facility to go into action, as also an acquired perfection in the action itself, the impression continuing the same, though the cause is diminishing.

These may be reckoned as secondary principles in an animal, and produce two very opposite effects, both according to their modes of impression.

Habit is the continuance of actions we have been accustomed to produce, without any immediate assistance, or even continuance, of the first cause, as a body set in motion continues to move after the cause of motion has ceased to act.

Custom arises from external impressions, either in the mind or body, and is of two kinds, one when, the cause continuing, the impressions, and consequently the actions, are diminished, the parts becoming habituated to the impression. We shall see the effect of this in our applications. If we apply a medicine to a sore, we shall affect it in one way or another, (it is immaterial which for the principal, but we will suppose it heals,) from becoming accustomed to that application, it shall lose the impression, and shall at last do nothing; therefore you will be obliged to make the application more stimulating, more active, or change it for something else. It is exactly so

with the mind; if a man goes into a strange place he is affected by the new objects about it; the next time he goes he is less struck; the third time less, till at last, when he goes into the place he can hardly perceive any thing strange in it. These very different effects arise from a difference in the degree of impression resulting from the state of the mind or body at the time. In the first instance, if the impression or cause be very slight, so as hardly either to alarm the part or the constitution, they will get familiar with it, and will become insensible to it; a ring on the finger, the use of snuff, our very clothes, and physic itself are striking and daily instances of this. The habit of insensibility will soon be formed if the sensations of the mind and body be not very acute. If the first impression be violent, and such as produces considerable effect, it is not necessary that the same degree of violence should be inflicted to produce a similar effect a second time. One can easily imagine that these impressions may be continued until the parts continue to act without the impression, which would then become habit. If a dose of an emetic be given, which affects the stomach much, the same quantity is not necessary a second time to produce the same effect; the second must be given, however, before the stomach has lost the impression of the first perfectly.

The same effect is produced on the mind as on the body, for whatever has made but a slight impression, soon wears out, and we think no more upon it. On the other hand, if an animal has met with anything that has affected its mind much, as fear, &c., it is not necessary for the object to appear in the same manner to produce a similar effect.

Those effects will be more or less, according to the state of the body or mind at the time of the first affection; the more irritable or the more ready it is to fall into the first action at the time, the more readily will it take it up the second time, although it may not be particularly irritable or susceptible of this particular action.

Habit.—A habit of acting arises from a repetition of acting, which repetition is custom, and which becomes the cause of the continuance of the same action. So that custom is always prior to habit, or, as it were, forms habit, which may be ranked as one of the secondary principles in the machine.

The first action being produced by a disposition in, or force upon, the part,

this being repeated or continued a sufficient length of time, the action at length goes on, when that original disposition or force is gone, until some other power counteracts it, or it wears itself out. The more we have been in the habit of thinking on any object, the more readily does the train of thinking relating to that object recur. This principle in the animal is similar to the vis inertiae in matter, for by it a motion begun is continued, and the remaining at rest is from the same cause. This principle becomes the cause of the actions of the mind; it does not allow men to think differently from what they have been accustomed to think. Men in general go through life with the same modes of thinking, and thus it becomes a cause either of the retardation or improvement of the understanding. It retards improvement, because it gets the better of even present sensations, and does not allow men to wander into novelty. It promotes improvement, because it makes men perfect in what they have been long engaged.

ON PULMONARY PHTHISIS IN CHILDREN,

By M. BAUDELLOCUE.

The following cases will serve to prove that the symptoms of pulmonary consumption in children are the same as in adults, whether these symptoms be local or general.

Julie Dupuis, aged three years and a half, was admitted into the hospital for sick children early in January. She was born of healthy parents, but had always been delicate. She was taken from nurse at two years old, and had a cough since that time.

During November and December, she was affected with acute pleurisy of the right side, which necessitated the application of leeches.

The traces of pleurisy were ascertained; thick false membranes seemed formed between the pleura and right lung. There is not greater development on the side of the chest than on the opposite side. The sound is not clear, the bronchial respiration weak. In auscultation the mucous rale is alone heard, the cough is dry, and the pulse only gives one hundred pulsations in the morning, but increases at night, which is also the case with respiration, which in the morning is only repeated thirty times per minute. The child has diarrhoea.

During the eight days, the child was in

the hospital, she did not get better, the parents took her away on the 30th, she died of suffocation on the 31st.

On the post mortem examination, we found general and intimate adhesions between the right lung, the costal pleura, and the diaphragm.

The left lung was free, the bronchial glands had undergone tuberculous degeneration. In the right lung white tubercles from the size of a grain of millet, to that of a grain of hemp seed, cover the surface, or the centre of the organ. In some parts they form groups about the size of a filbert, round which the pulmonary tissue is indurated. The left lung is equally covered with tubercles, they are spread in two lobes, and as near the basis as the summit, none of them are soft. Some of these productions are also found in the false membranes lining the right lung. Ulcerations, and sub-mucous tubercles were found in the intestines, as well as in the liver and spleen.

Reine Hervet, eleven years of age was admitted into the hospital, on the 25th of January. Her father had a complaint of the chest, and died of the cholera. One of her brothers died at eighteen, of consumption, and one of her sisters at twenty-four, of the same disease. In her infancy she had various exudations of the scalp, and glandulous congestions of the chest, which went off. She had the measles at seven, a continued bronchitis accompanied the exanthema, and lasted some time after it had disappeared. At this period a blister was applied to the arms, and the patient still keeps on a blister; the catarrh which succeeded the measles disappeared in a few months; the patient recovered her strength and grew fat; but the cough came on again, then ceased, then re-appeared. For the last ten months the patient had not ceased coughing, she spit blood several times but not in any great quantity. She complained of great pain between her shoulders, has been subject to diarrhoea and gradually wasted away. For the last three months her voice has become weak; fever towards evening, and nocturnal perspirations. The appetite has continued good: and the patient has had sufficient strength to get up every day.

On the 26th, at the morning visit, we ascertained the state of the patient to be as follows:—Dorsal decubitus, redness of the upper part of the cheek, contrasting with the paleness of the rest of the face, general thinness, œdema around the malar bones, light hair, blue eyes, long eye

lashes, well shaped thorax. Frequent cough, slight expectoration, the voice very feeble. On percussion, we found a *son mat* from the clavicle to the breast both right and left; on applying the ear to this region, a cavernous sound was distinctly heard and sero-purulent rattlement.

On the left this latter sign is wanting, but the cavernous respiration is evident. The respiration is accelerated 32 respirations in a minute, the pulse beats 80 or 90 times a minute in the morning, and rises to 100 or 120 in the evening. The bowels are not active; slight pressure on the abdomen gives no pain, the diarrhoea has ceased. She has a good appetite, asks for food, and wishes to get up; she is in full possession of all her faculties. Gummy beverage, mixture with half an ounce of syrup, broth, and an egg. During the three following days, the patient got up and took food.

The 29th she was up part of the day, in the evening she was taken suddenly with a pain in the right side of the chest, and with intense dyspnea.

The 30th the patient could not lie down, she sat up in bed, her lips were violet: the dyspnea violent: 72 respirations a minute, the pulse quick. The child expired at five in the afternoon.

The body was opened forty hours after death, the membrane of the larynx, the trachea, and bronchii red and thick in several places, no erosion or ulceration. The bronchial glands are hypertrophied, a very small number have undergone tuberculous degeneration; adhesions of long standing, unite the summit of the two lungs to the thoracic coats. The right pleural cavity contains about three glasses of serosity tinged with blood. That on the opposite side is empty. The three lobes of the right lung are strictly united. In the upper lobe is an excavation large enough to hold an egg, and containing brown pus.

The tissue forming the walls of this cavern is indurated; when cut in thin pieces, it falls to the bottom of the water. In the two other lobes there are several small excavations large enough to hold a pea or a filbert. In the interval there are rough tubercles, and infiltrated tuberculous matter. In the inferior lobe are some portions of pulmonary tissue, air proof. To the left, large excavation, irregular at the top. The same alteration of the pulmonary parenchyma as to the left. Nothing in the heart or pericardium. The stomach large. The mucous membrane pale, and partially softened.

In the small and large intestines there are some submucous tubercles and some ulcerations. In the interval the mucous membrane has pretty good consistence.

The matter contained in the rectum is solid. The mesenteric glands are rather more developed than in the normal state, but are not tuberculous. The liver, spleen, and kidneys are free from alteration, as well as the encephalus and its appendages.

3rd. CASE.—Antoinette Micotte, 14 years of age, was admitted into the hospital on the 10th of January. She was rather tall, and the thorax well formed, her father died of a consumption at the age of forty-three: she is the youngest of fourteen children by the same father, who all died before they reached their tenth year. The mother has good health. In her infancy, Antoinette had congestion of the cervical ganglions, which have since disappeared. She had the measles at eight years old, but had no cough, after this complaint. Ten months since she was attacked with acute affection of the chest, which confined her to her bed for several days. She however was soon convalescent. Three months since, this girl left Auvergne, to come to Paris. She had a cough, with great pain in the length of the sternum, the diarrhoea came on. These symptoms continued till the patient was received into the hospital. During these three months, she expectorated blood in small quantities, the cough continued, and was sometimes so violent as to induce vomiting; she became feverish towards night. Her appetite continued good; a seton on the arm, blister on the chest, and pectoral beverage were prescribed.

When she came to the hospital, she was pale and thin; and so weak that she was compelled to remain in bed; she is hoarse, and the cough frequent, night and day. A dull sound is heard in the whole extent of the chest; and on the ear being applied to the subspinous region, there is pectoriloquy, catarrhal rale; lower down, there is a mucous rale. The catarrhal rale and pectoriloquy are equally manifest in front between the breast and the clavicle. On the right, the sound is clear, the respiratory noise is heard distinctly.—The expectoration is grey, puriform, and contains streaks of blood and opaque lumps. The respiration is accelerated, 32 respirations in a minute; the pulse 96 in the morning, but increases in the evening. Towards four o'clock the face becomes red, the skin heated, the pulse increases and persists until the morning,

when abundant perspiration comes on. The abdomen voluminous—the stools numerous, but no cholice. An infusion of marsh mallow was prescribed, and a mixture with 1, then 2 grains of tartaric stibiate, pills of digitalis and sulphate of quinine.

The mixture of stibiate disagreed with the patient, it brought on nausea, and vomiting; no improvement took place: and an attack of dyspnea terminated fatally the 31st of January.

At the post mortem examination we found an enormous tuberculous excavation at the bottom of the superior left lobe; ancient adhesions unite the summit of the left lung to the costal pleura. In the inferior lobe there are several other tuberculous excavations, but of smaller dimensions, and in the interval, raw tubercles, the bronchi on the left side are red, the bronchial glands hypertrophied, and transformed in tuberculous masses. The left lung has no cavern, but there are small tuberculous lumps, and milliary tubercles in great number; various parts of the pulmonary tissue are indurated.

The peritoneum contains a pint of transparent serosity, the ganglia surrounding the liver and pancreas, have undergone tuberculous degeneration. The stomach is spacious, its surface pale and thickened. In the lower half of the small intestine, and in the large intestine, there are several ulcerations; some spread round this canal. There is nothing remarkable in the other viscera.—*Continental and British Medical Review.*

OBSERVATIONS ON THE DIAGNOSIS OF PNEUMONIA.

BY DR. ADDISON.

(From *Guy's Hospital Reports.*)

Any attempt at a further elucidation of pneumonia, after the splendid performances of Laennec, may probably appear presumptuous; and especially so, when made by one who acknowledges himself indebted for almost all that he knows of thoracic diseases to that truly great man, at once the most distinguished and most successful cultivator of medical science that ever adorned the profession. When, however, it is recollected how vast and barren was the field of his inquiries when he commenced his brilliant career—and when our former ignorance is compared with the knowledge that resulted from his unprecedented discoveries—our astonish-

ment is, not that he should have left something undone, but that he should have done so much. It is with the most profound deference and respect for his memory therefore, that I venture to add this tributary mite to the riches of one of his favourite essays. I cannot but feel, also, that some apology is due to the profession, for presuming to direct attention to a subject with which the works of Laennec must already have made them familiar; and particularly to those who have so far resisted the influence of prejudice as to have made themselves conversant with the use of the stethoscope. My apology is, that the very familiarity of the subject appears to have lulled medical men in general, and even the stethoscopist, into a too passive confidence in what is already known: and has probably proved a check to that correction and improvement which Laennec himself was at all times so eager to accomplish.

The main object of this brief communication is, to make some addition, however trifling, to the ordinary means of diagnosis; since experience has forced upon me the conviction, that there are few acute diseases more frequently mistaken or overlooked than pneumonia, to the detriment of the patient, and no small embarrassment of the practitioner.

In order to make myself understood, I may perhaps be permitted to take a very slight survey of the pathology, signs, and symptoms of the disease; merely observing, at the outset, that, in doing so, I shall adhere as closely as possible to the purely practical tenor of our Reports; indulging in theory no more than is unavoidable, in arranging and reasoning upon facts derived from the sick chamber and the dissecting-room. To the facts, or supposed facts, alone, do I attach any importance. The use of these facts must be left to the judgment and discernment of the reader.

In pneumonia, the inflammation is manifestly seated in or around the air-cells, or in both situations. It is perhaps of little importance, whether we conclude it to be seated primarily and essentially in the one or in the other of these structures: although, for my own part, I entertain no doubt whatever of its being primarily and essentially seated in the interior of the cells themselves—a belief drawn from the successive local changes observed to take place as the disease advances. In the first stage of the disorder, we find the cells red, and filled with a serous-looking and sometimes bloody

fluid, rendering the lungs more heavy, dense, and œdematous, whilst they still retain their tenacity. At a more advanced period, or second stage, the cells are found filled up with red solid matter, which appears to consist of the thickened parietes of the cells themselves: for if the lung be torn, and the torn surface examined with a magnifying-glass, it seems to be made up of innumerable minute red grains, just such as one might conceive to result from a filling up of the cells in the manner supposed. At this period, the serous-looking fluid has disappeared, the lung is comparatively dry, and the tenacity of the solidified part is so far diminished, that it may be readily broken down by forcing the finger into it: this is what has been called red hepatization. At a later period, and sometimes apparently without having been preceded by the red granules, the solidified lung presents a grey appearance, an albuminous matter seems to occupy the place of the granules, or rather their centres, constituting the grey hepatization. This albuminous matter is sometimes firm and fixed, at other times it is less plastic, and occasionally, especially in bad constitutions, takes on a more decidedly purulent aspect, and may be squeezed out by pressure; or, as the cohesion of the pulmonary tissue is often, under such circumstances, very much diminished, the slightest pressure of the finger causes it to break down into a semi-fluid mass, resembling an abscess.

It is not necessary to be more minute in describing the pathological changes which take place in the progress of pneumonia: it is sufficient to remember, that, in the first stage, the cells contain air and serous-looking and sometimes bloody fluid, as shown by the peculiar crackling sound, and escape of the fluid on squeezing a cut surface; that, in the second stage, the cells are solidified, comparatively dry, and, sooner or later, have poured into them an albuminous matter, either solid and fixed, or, more rarely, a matter approaching the character of pus. The stethoscopic signs indicative of these respective changes are such as might be expected, and are easily understood. Whilst the cells contain air and serous fluid, there is little or no dullness of sound on percussion, but during respiration, we hear the crepitating rattle—a rattle which undoubtedly depends upon the presence of air and fluid in the cells, for it is observed in cases of œdema of the lungs, and in some instances of pituitous catarrh, as well as in the first stage of pneumonia.

When the cells are solidified, and admit no air, we have dulness of sound on percussion, bronchophony, and bronchial respiration, at least when the consolidation is considerable, and seated near the surface. Such are the stethoscopic signs of simple pneumonia: they are quite characteristic, and are pretty uniformly present, except under very peculiar circumstances.

If an opportunity present itself of examining the body, when a lung consolidated by pneumonia is retreating towards a recovery of its normal state, we commonly find the cut surface of the portion previously hepatized of a pale or pinkish hue; or we find it presenting a mixture of pale, pink, and grey: it is still more friable or lacerable than natural; and the cells are again more or less loaded with serous-looking fluid, rendered frothy by squeezing the lung, in consequence of the presence of a considerable number of air bubbles. It would also appear, that the further changes consist in the absorption of the effused fluids, a gradual increase of the tenacity of the pulmonary tissue, and a more or less complete restoration of the normal state. In some instances, however, when the albuminous matter thrown out is of the more plastic or organizable kind, it fails to be entirely absorbed, and part of it permanently remains. Under these circumstances, we find it, at an after-period, either in small detached, and more or less rounded masses, or more extensively and more irregularly diffused through the pulmonary tissue. When distributed in small insulated portions, I believe it to constitute one of the forms of albuminous deposit, indiscriminately called tubercles; whereas, when more extensively and irregularly diffused, it has, in like manner, been regarded as a form of tubercular infiltration. The history, however, of the patients case, in many instances, as well as the local appearances themselves, lead me to the conclusion, that they are merely the result of a previous attack of pneumonia. We often learn, on inquiry, that, at some former period, perhaps years before, the patient had an attack of inflammation within the chest; whilst, if he die of some other disease, we almost uniformly discover, on dissection, unequivocal evidence of antecedent inflammation. The evidence consists in thickening and adhesions of the pleuræ, especially in the neighbourhood of the appearances in question, together with induration and puckering of the pulmonary tissue imme-

diately surrounding each albuminous deposit: or, when the deposit is irregular and extensive, we often have an actual deformity and puckering of the pleura above the infiltrated parts. This view of the of these albuminous deposits will probably serve, in some measure, to explain why they are much less uniformly found in the apices of the lungs than ordinary tubercles.

It has been observed, that these deposits may remain passive for an unlimited period, and without undergoing any very appreciable change, except perhaps a conversion of some of them into calcareous or chalky masses, especially when deposited in the upper lobe of the lung: it would nevertheless appear, that the vital influence by which they are maintained in their integrity is so extremely slender, that if inflammation happen to be set up around them by any accidental cause, and especially if the vital powers of the patient have been greatly impaired, that influence is so far exhausted, that they lose their cohesion, and soften;—the softening commonly first taking place in those portions most remote from the more highly organized living structures: they soften in the centre; the softening proceeds outwards, and, in the end, causes the formation of vomica, and so produces one of the modifications of phthisis pulmonalis. Such, at least, are conclusions to which repeated observation of the living, and dissection of the dead, have led me, in regard to this part of the subject.

Having premised these very superficial remarks, I shall now proceed to the reputed functional signs or symptoms of pneumonia; for it is to the unsteadiness and fallaciousness of these, that errors in diagnosis are chiefly attributable; and, consequently, it is to them more particularly that I am desirous of directing attention.

The characteristic symptoms of pneumonia enumerated by Laennec, are, in an *obtuse and deep-seated pain in the chest, dyspnœa, hurried respiration, cough, and peculiar expectoration*: but, in reference to these, he tells us, that each of them individually may occasionally be absent, and, indeed, that they may all be absent in the same case. Now, were it quite correct to assume that the character of pneumonia is that which is expressed by the above symptoms, that the reputed deviations and exceptions alluded to by Laennec are only of very rare occurrence, and that obscurity happened only in the pneumonia of old people, and in cases

complicated with other diseases, there might probably be some excuse for resting satisfied with the present position of the subject: but if it be as true, as I am convinced it is, that these reputed deviations and exceptions, regarded as obscure, are of extremely frequent occurrence, that they are met with at every period of life, and in every variety of constitution; and that they are very far indeed from being limited to old persons, and to what have been called complicated cases; I hope to be pardoned if I make an attempt, in some degree to unravel the difficulty, and place the subject, if not in a more safe and practical point of view.

I have been led to the conclusion, that cases of pneumonia characterised by obtuse and deep-seated pain, dyspnoea, hurried respiration, cough, and peculiar expectoration, are, in truth, themselves the exceptions, in a pathological sense; and that although most frequently met with in practice, they are, in fact, cases of complication. It may be said, if such cases of complication be those most commonly encountered in practice, why interpose a mere pathological subtlety, to disturb the practical rule? To this I oppose my belief, that it is an adherence to such a general character of pneumonia that has led, and is constantly leading, to an oversight—to a neglect of the disease, when it occurs in what I am disposed to regard as its more *simple form*: and as cases partaking more or less of this simple form of pneumonia are of frequent occurrence, I am willing to persuade myself that what follows may have the effect of diminishing the liability to the errors alluded to.

In *simple pneumonia*, after chilliness, shivering, feebleness, and depression, the patient experiences, for the most part, strongly-marked symptoms of febrile reaction, giddiness, confusion, and sometimes intense pain in the head; occasionally delirium, especially towards night; *the skin acquires a pungent heat*, generally accompanied by dryness, more rarely by moisture; the pulse is full and strong, perhaps labouring and sluggish; the face is usually more or less suffused with a livid flush, accompanied by an expression of distress; the tongue is foul; its substance is more injected than in ordinary phlegmasia, and in a short time it manifests a tendency to become dry and brownish; the respiration is somewhat hurried, but *there is seldom any very obvious cough or expectoration, and sometimes none at all*; in short, the whole assemblage of symptoms bears a most

striking resemblance to those of a severe attack of common continued fever of the typhoid type, for which it is so repeatedly mistaken. If this form of the disease occur in moderately good constitutions, and is overlooked, especially if stimulants be administered on the supposition of its being a severe case of typhoid fever, it very commonly happens that the general prostration increases, the delirium or oppression of the brain is aggravated, the tongue gets dry and black, and the teeth covered with sordes; the breathing becomes more hurried, occasionally with a frequent slight hacking cough, and now and then a little bloody expectoration; the pulse gets flaccid, frequent, and feeble; and at length the patient dies.

Notwithstanding its close resemblance to a severe attack of continued fever—a resemblance so great, that even the stethoscopist is occasionally thrown off his guard—attentive observation will, in most cases, enable us to recognise the difference. The attack, in general, is more abrupt, and often follows some manifest exposure to cold or wet. The countenance, though congested and somewhat distressed, has not the dejection and stupidity so remarkable in fever; it displays more intelligence, and, although confused and perhaps slightly delirious, the patient on being roused, commonly evinces a clearness and vigour of intellect not found in fever. The condition of the tongue also furnishes a valuable diagnostic sign. We know that, at the onset of fever, the contrast between the vividly-injected tongue and its white or grey fur is very striking; it is, in general, much less so in pneumonia. In the latter, if I may be allowed the expression, it is more the tongue of a phlegmasia; the hurry of respiration in pneumonia is often not more than we commonly perceive amid the general distress of fever; and I repeat, that neither cough nor expectoration is necessarily present in a very appreciable degree. But of all the symptoms of pneumonia, the most constant and conclusive, in a diagnostic point of view, is *a pungent heat of the surface*. By this symptom alone, the first stage of pneumonia may, in most instances, be readily recognised: by this symptom alone, I have repeatedly pronounced the existence of pneumonia, before asking a single question, or making the slightest stethoscopic examination of the chest. The presence of this symptom has scarcely ever yet deceived me, even in the most complicated forms of inflammation within

the chest. I by no means contend that it is necessarily present at some period of every case, although I do not know to the contrary; but I feel justified in affirming, that when inflammation is confined to the chest, however varied may be the tissues involved in the inflammatory process, provided this symptom be present, pneumonia may be confidently pronounced to form a part, in nineteen cases out of twenty, and I believe in a much larger proportion.

A similar pungent heat of the surface is now and then observed in certain forms of renal dropsy; more frequently in continued fever, especially in children; and still more commonly in the eruptive fevers of the exanthemata and erysipelas; and, as such cases may supervene upon already existing disease within the chest, the fact ought to be carefully remembered, lest a most valuable diagnostic sign should rather mislead than assist us. It is in original inflammation within the chest that it proves so constant and conclusive a sign of pneumonia, but on every occasion, when present, it ought to lead to a most careful scrutiny, by means of the stethoscope.

I am unwilling to swell this communication by a detailed recital of individual cases, but were it otherwise, it would be easy to introduce a very great variety of instances, in which simple pneumonia has been mistaken for common fever of a typhoid type. I have repeatedly witnessed it in children; the first suspicion of it having been generally suggested to me by recognizing, on applying the hand to the surface, the peculiar pungent heat already noticed. I not long ago had an example in a young woman who was supposed to be labouring under a severe attack of bilious fever; so called, because pneumonia of the right lung was accompanied, as is not unfrequently the case, by a sallowness, or almost jaundiced aspect of the patient's countenance. I have a very similar case in Miriam's Ward at this time, also occurring in a young female. In elderly persons it is so common, that when a case of typhus is represented to have occurred in any individual above fifty years of age, without evidence of the existence of the disease in other branches of the family, I confess that I considered it at all times an equal chance that it is, in reality, a case of pneumonia. An instance of this kind I saw very recently: the person was upwards of sixty, but of a hale constitution, and presented most of the ordinary signs of continued

fever, whilst the pulmonic symptoms were so slight as never to have attracted the least attention. This brief representation may probably suffice to fix attention upon the likelihood of the presence of pneumonia in cases of supposed continued fever.

The more simple form of pneumonia not unfrequently assumes another appearance, which has occasionally led to a belief that the brain was the seat of the disorder; the original affection of the lungs being so obscure as to be entirely overlooked. I have, within a short period, seen two cases of acute pneumonia in vigorous adults, in which, at the commencement, and for some days, the disturbance of the brain was such, that remedies were applied exclusively for the relief of that organ. In both instances, the inflammation was very intense, and was, at a latter period, attended with cough, expectoration, and other signs commonly regarded as characteristic of pneumonia.

Some time ago I was requested to see an elderly man, who appeared to be labouring under obscure symptoms of mental aberration, and was supposed to have become insane. He looked pale, his countenance was somewhat anxious, his tongue was loaded, slightly brown, and disposed to become dry, he was occasionally incoherent, and wandered about the ward in a wild and unaccountable manner, but had neither cough nor expectoration sufficient to attract any particular. On examination, I found him labouring under pneumonia already advanced to hepatization. He recovered. A similar case is now under treatment in the hospital.

In infants and very young children, such cases are by no means rare, and stimulate hydrocephalus. In one instance where hepatization had taken place, the most prominent symptom was convulsions, for which various applications had been made to the head.

Such are some of the affections of the brain, to which pneumonia not unfrequently gives rise—secondary affections, calculated to mislead the most wary, and such as must inevitably distract the attention, and perplex the judgment of those who do not habitually have recourse to the stethoscope.

If the representations I have made be correct, they certainly lead to an inference, that even acute disease does not, when confined to the air-cells, necessarily give rise either to cough or expectoration

—symptoms, perhaps, too much relied upon, in recognising, or even suspecting, affections of the lungs.

Without arguing the question, whether it be possible to expectorate a thin watery fluid, which must necessarily gravitate in the cells of the lungs, I may venture to state, that I entertain very strong suspicion that the cough and expectoration so commonly observed in pneumonia depend altogether upon the accidental implication of the bronchial tubes, and that, without a doubt, the degree of these symptoms depends upon the degree of that implication. Certain it is, that the most intense pneumonia may exist, even in hale constitutions, with cough and expectoration so slight as to pass unnoticed; and it is not difficult to suppose, that, when so slight, they may depend rather upon mere sympathetic irritation of the minute bronchial tubes in the immediate neighbourhood of the inflamed tissue, than upon any considerable degree of actual inflammation set up in them. It is true, that, on dissection, we very commonly find the mucous membrane of the smaller tubes reddened; but whether from inflammation, or not, is by no means so easily determined. I am disposed to think, that, in simple pneumonia, the small tubes are either not at all inflamed, or only inflamed in a very slight degree, and that, when more decidedly involved, their inflamed state gives rise to the cough and peculiar viscid expectoration described as characteristic of pneumonia in general. This complication is indisputably more frequently present than absent; a circumstance little calculated to excite surprise, and one probably sufficient to account for the symptoms which attend the complication, having usually been described as those essential to, and characteristic of, pneumonia.

When cough and expectoration are as well marked as they are commonly described to be, they cannot fail to attract the attention of every one, and all difficulty of diagnosis ceases. The same may be said of those cases of pneumonia in which we have the mucous membrane of the bronchial tubes involved to such an extent, that, by universal consent, the disease is said to be complicated with bronchitis, and in which we have the expectorated mucus, though considerable in quantity, more or less tinged of a brownish or saffron colour. It does not, however, necessarily follow, that, when pneumonia is present, the mucus of the accompanying bronchitis shall be tinged brown: ou

the contrary, the discoloration is often, in such cases, altogether absent, its presence and degree depending upon the quantity of blood which happens to be effused; exactly in the same manner as the ordinary *viscid sputa* of pneumonia may be colourless, or may be of a gamboge yellow, light green, or of a rusty or red colour, according to the same accidental circumstance. Of course, in these bronchial complications, we have, superadded to the stethoscopic signs already mentioned, a mucous rattle, which, when hepatization takes place, is rendered much more distinct, in consequence of the consolidated lung being a better conductor of sound.

In concluding this slender contribution to diagnosis, I shall merely observe further, that unless complicated with pleurisy, pain of any sort is rarely complained of by a patient affected with simple pneumonia, in whatever position he may be placed. When, however, the bronchial complication is such as to produce severe cough, he not unfrequently experiences a burning or tearing pain, or rather soreness, more or less diffused through the affected parts—a symptom probably resulting from the violence inflicted upon the inflamed tissue during the repeated fits of coughing.

THE ANATOMIST.

Foramen commune anterius, is the hole by which the choroid plexuses unite anteriorly. It forms a medium of communication for the two lateral and the third ventricles.

Infundibulum, an opening leading from the anterior and inferior part of the third ventricle to the pituitary gland.

Iter a tertio ad quartum ventriculum, an opening in the posterior part of the third ventricle, under the posterior commissure and tubercula quadrigemina, and leading obliquely backwards and downwards to the fourth ventricle.

Anterior commissure, a medullary, round cord, anterior to the crura of the fornix, and passing transversely from one corpus striatum to the other.

Posterior commissure, extends transversely from one optic thalamus to the other. It is shorter and smaller than the anterior commissure.

Tubercula quadrigemina, four eminences, called also *nates* and *testes*; situated under the posterior part of the velum

interpositum, and the pineal gland; the two anterior, the nates, are connected to the optic thalami; the posterior, the testes, being connected to the cerebellum by the following processes.

Processus a cerebello ad testes, two thin medullary plates, which pass obliquely from the cerebellum upwards and downwards to the testes.

Valve of Vieussens, a layer of cineritious substance, of a triangular form, attached by its sides to the processus cerebello ad testes, by its base to the cerebellum, and by its apex to the testes.

Fourth ventricle, is exposed by cutting through the valve of Vieussens. It is bounded anteriorly by the pons Varolii, laterally by the processus cerebello ad testes, superiorly by the valve of Vieussens, inferiorly by pia mater and arachnoid membrane, and posteriorly by the cerebellum.

Calamus scriptorius, the fissure seen upon the posterior surface of the pons Varolii, in the fourth ventricle; from either side of which four or five lines proceed.

Choroid plexus of fourth ventricle, a small fold of pia mater, which enters the ventricle as this membrane, is passing from the cerebellum to the spinal chord.

CEREBELLUM,

Consists, like the cerebrum, of two hemispheres, united anteriorly by the pons Varolii, and posteriorly by the superior and inferior vermiform processes.

Hemispheres, are flat superiorly, where they correspond to the tentorium, and convex inferiorly where they rest in the inferior occipital fossa: the surface of each presents semicircular narrow lines, arising from the laminated arrangement of the cineritious portion of the organ; between these lamina the pia mater enters, but the arachnoid passes over them.

Crura cerebelli, two medullary chords which pass from either hemisphere and unite in the pons Varolii.

Superior vermiform process, a small conical eminence corresponding to the superior and central part of the cerebellum.

Inferior vermiform process, larger than the superior and corresponding to the inferior and central part of the cerebellum and the commencement of the spinal chord.

Arbor vitæ, the branching of the medullary substance of the cerebellum, and exposed by making a vertical section.

Corpus dentatum, a small oval mass of cineritious substance, surrounded by me-

dullary, and exposed upon making a section of the cerebellum parallel to, but an inch distant from, the median line.

MEDULLA OBLONGATA,

A large conical process of medullary structure, extending from the lower margin of the pons Valorii to the commencement of the spinal chord. It is rather more than an inch in length and presents the following six bodies, which are separated from each other by distinct grooves.

Corpora pyramidalia, the two anterior eminences of the medulla oblongata.

Corpora olivaria, smaller than the pyramidal bodies, are situated laterally.

Corpora testiformia are large, and situated posteriorly.

BASE OF THE BRAIN

Presents on either side of the median line, the anterior and middle lobe of the cerebrum, separated from each other by the fissure of Sylvius, and a lobe of the cerebellum resting upon the posterior lobe of the cerebrum. In the median line, proceeding from before backwards, is the anterior extremity of the median fissure, the lower extremity of the corpus callosum, the optic commissure, the tuber cinereum, the corpora albicantia, the pituitary gland and infundibulum, the locus perforatus, (on either side of this is the crus cerebri,) the pons Varolii, and lastly the posterior extremity of the median fissure.

ORIGIN OF THE CEREBRAL NERVES.

First pair (olfactory), each arises by three roots, the external, long and white from the fissure of Sylvius; the internal, also white from the posterior internal surface of the under part of the anterior lobe and the middle, short, cineritious, from the posterior edge of the anterior lobe.

Second pair (optic), each arises by two roots from the corresponding notis and testis; that from the nates joins the corpus geniculatum externum, the other the corpus geniculatum internum; the roots then unite and form the tractus opticus, this passes around the crus cerebri, to which it is united by fine cellular tissue, the tracts, one from either side, then unite in the optic commissure, having previously sent a few fibres into the tuber cinereum and from the anterior part of this commissure proceed the optic nerves.

Third pair (oculo-muscular), each arises from the inner side of the crus cerebri, near the pons Varolii, and from the corpus pyramidale, as this body passes through the pons.

Fourth pair (inner oculo-muscular), each arises from the processus δ cerebelli or its corresponding side by two or three fine ligaments.

Fifth pair (trigeminal), consists of two portions, one for sensation, the other for motion. The motion division arises from the corpus pyramidale, with the pons varolii, and the sensory division from the angle between the crus cerebelli and the pons varolii.

Sixth pair (abducentes), each arises from the corpus pyramidale near its junction with the pons varolii.

Seventh pair consists of the *portio dura*, or facial, and the *portio mollis*, or auditory. The *portio dura* arises from the groove between the corpus pyramidale and olivare, a little below the pons varolii. The *portio mollis* arises by three or four white lines from the calamus scriptorius in the fourth ventricle.

Eighth pair consists of the *glossopharyngeal*, *pneumo-gastric* and *spinal accessory*. The *glossopharyngeal* arises from the groove between corpus olivare and corpus resitiforme, by four or five filaments. The *pneumo-gastric* arises in the same groove, but below the glossopharyngeal, by eight or ten filaments, and the *spinal accessory* arises from the side of the cervical spinal chord, about its middle, by several filaments.

The ninth (linguales) each arises by seven or eight filaments from the groove between the pyramidal and olivary bodies, about half an inch below the origin of the sixth.

CEREBRAL NERVES.

First pair (or olfactory), sends off three sets of branches. *Internal branches* to septum nasi; *middle branches* to mucous membrane of roof of each nostril; and *external branches* to spongy bones.

Second pair (or optic), pierces sclerotic coat of eye, and form the retina.

Third pair (or motores oculorum). *Superior, or smaller branch*, supplies the superior rectus, and the levator palpebræ. *Inferior, or larger branch*, supplies the internal rectus, the inferior rectus, and the inferior oblique; and also sends a branch to the recticular ganglion.

Fourth pair (or pathetici), are distributed to superior oblique muscles of eye. gasserian ganglion, and divide into three

Fifth pair (or trigemini), first from the main branches. *Ophthalmic division*.—1. Descending branches to unite with the sympathetic. 2. Lachrymal nerve, which sends a branch through the sphenomaxillary fissure, to unite with the superior

maxillary nerve, a branch through the malar bone to the cheek (called cutaneous malm), the terminal branches being distributed to the lachrymal gland, and the conjunctiva. 3. Frontal nerve, sends a branch to unite with the infra-trochlear branch of the nasal—a supra-trochlear branch, which becomes the internal frontal, and the proper frontal, which passes over the frontal bone to the forehead. 4. Naso-ocular nerve, which sends a branch to communicate with the sympathetic—a branch to the third pair—two long ciliary nerves—a branch to the lenticular ganglion—the infra-trochlear branch, and the nasal branch. *Superior maxillary division*.—1. Orbital branch, sends off a malar twig and a temporal twig. 2. Two branches to Meckel's ganglion. 3. Posterior dental, sends of an anterior branch to the buccinator muscle and gums, and a posterior branch to the molar teeth. 4. Anterior dental, to the antrum and teeth. 5. Infra-orbital, distributed to the face. *Inferior maxillary division*. 1. Superior or external branch sends off deep temporal twigs, a masseteric branch to masseter muscle and temporo-maxillary articulation, a buccal branch to the buccinator, temporal and pterygoid muscles, and a pterygoid branch to the pterygoid and palatine muscles. 2: Inferior or internal branch, sends off the temporo-auricular, which goes to the cartilages of the ear and temple—the inferior dental, which gives off the mylo-hyoid nerve, and the mental nerve; lastly, the second division or the gustatory, to muscles, glands, and papillæ of the tongue; it is joined by the chordi tympani nerve.

GANGLIONS IN CONNEXION WITH THE FIFTH PAIR.

Gasserian Ganglion.—A large grey semi-lunar body, placed in the middle fossa of the base of the cranium, concave posteriorly, where it receives the fifth nerve, and convex anteriorly and externally, from which part proceed the three main divisions of the fifth, just described.

Meckel's Ganglion.—A little red body of a triangular shape, situated deep in the fat and cellular tissue of the pterygomaxillary fossa; it communicates superiorly by two small nervous twigs with the second division of the fifth, and sends off—1. Spheno-palatine nerve to the mucous membrane of the superior and middle spongy bones, from which proceeds the naso-palatine branch, which runs along the septum nasi, and terminates in the

foramen incisivum. 2. Palatine nerve, descends in the palatine canal, and divides into anterior branches which supply the teeth, and posterior and middle branches, which supply the amygdalæ soft palate, uvula. 3. Vidian nerve, passes backwards through the vidian canal, enters the cranium by the foramen lacerum anterius, and divides into an inferior and a superior branch, having first sent filaments to the sphenoidal sinus; the inferior branch enters the cavernous sinus, and unites with the branches of the sympathetic, whilst the superior branch runs beneath the lasserian ganglion on the petrous portion of the temporal bone, enters the hiatus Fallopii, attaches itself to the portia dura nerve, again leaves it, and enters the tympanum a little below the pyramid, and is here called chorda tympani. It then passes between the long crus of the incus and the handle of malleus, emerges from the tympanum by the glenoid fissure, unites with the gustatory nerve, and at the submaxillary gland it terminates in a small ganglion named after Boch.

The *lenticular ganglion* is situated between the optic nerve and external rectus muscle; it receives at its posterior superior angle a branch from the nasal branch of the fifth, and by its posterior inferior angle a branch from the inferior division of the third. Its anterior angles furnish the ciliary nerves, about twenty in number, which run along the optic nerve, pierce back part of the tunica sclerotica, run forward between it and the choroid coat, enter the ciliary ligament, and are ultimately distributed to the iris.

The *naso-palatine ganglion* is said to exist in the anterior palatine hole, and to be formed by the anterior palatine branches from Meckel's ganglion.

The *submaxillary ganglion* lies at the edge of the submaxillary gland, and seems to be formed by the termination of the chorda tympani nerve.

Sixth pair, or abducentes, are distributed to the external rectus muscle of each side exclusively, but receives two filaments from the sympathetic in the cavernous sinus.

Seventh pair consist of two portions, viz.:—*Portio dura* and *portio mollis*.

Portia dura, or facial nerve.—1. Twigs to tensor tympani and stapedius muscles. 2. Posterior auricular. 3. Stylo-hyoid nerve to the digastric and styloid muscles. 4. Submastoid nerve. 5. Cervico-facial division, which sends off maxillary branches, submaxillary branches, and cer-

vical branches. 6. Temporo-facial division, which sends off temporal branches, malar branches, and buccal branches. *Portio mollis*, or auditory nerve. 1. Branch to cochlea. 2. Branch to vestibule and semicircular canals.

Eighth pair, or par vagum, consists of three portions, viz.:—Glosso-pharyngeal, pneumo-gastric, and spinal accessory. *Glosso-pharyngeal*, or first branch of the eighth. 1. Twigs through the temporal bone to the carotid plexus in the cavernous sinus. 2. Branches to the pharyngeal plexus. 3. Branches to the tonsillary plexus. 4. Branches to the ligo-glossus, stylo-pharyngeus, and superior and middle constrictors of the pharynx, mucous membrane of fauces, &c. 5. Branches to the papillæ and mucous membrane at the root of the tongue. *Pneumo-gastric*, or second branch of the eighth. 1. Branches to unite with the spinal accessory, glosso-pharyngeal, lingual, and sympathetic nerves. 2. Branches to assist in forming the pharyngeal plexus. 3. Superior laryngeal nerve, which sends a branch to the pharyngeal plexus—external branches to the sterno and thyro-hyoid muscles, thyroid gland, and cartilages of larynx, and an internal branch pierces the thyro-hyoid membrane, and supplies the epiglottis and mucous membrane, and sends a long branch to the crico-thyroid muscle. 4. Cardiac branches, which join the cardiac nerves of the sympathetic. 5. Inferior laryngeal or recurrent nerve sends off cardiac filaments—branches to the forepart of the trachea and thyroid gland, and branches to the pharynx, laryngeal muscles, and mucous membrane, on which they communicate with branches of the superior laryngeal. 6. Pulmonary branches send off branches which pass in front of the bronchial tubes to form the anterior or lesser pulmonary plexus, which plexus sends filaments to the pulmonary vessels, also to the lungs and pericardium, and to the posterior pulmonary plexus. 7. Posterior, or greater pulmonary plexus is formed by the vagi nerves which increase in size at the root of each lung, and subdivide and unite in an areolar manner. This plexus is joined by several branches of the sympathetic nerve, and its branches accompany the bronchial tubes through the substance of the lung. 8. Œsophageal plexus or plexus gulæ, is formed by the communications of both nerves, encircling the Œsophagus in their course along this tube. 9. Cardiac, or gastric plexus, is formed by both nerves dividing, subdividing, and

uniting upon the stomach. The left vagus nerve is anterior upon the stomach, and sends branches to the lesser omentum and liver; the right is posterior. *Nervus accessorius*, or third branch of the eighth.

1. Branches to communicate with the eighth, ninth, and sympathetic nerves.
2. Branches to the sterno-cleido-mastoid muscle, which muscle it then perforates.
3. Terminal branches to the trapezius muscle and skin.

Ninth pair, or lingual. 1. Descendens noni receives a filament from the pneumogastric, unites with the internal descending branches of the cervical plexus, forming a small triangular plexus, the branches of which pass to the omo and sterno-hyoid and thyroid muscles. 2. Branches to the constrictors of the pharynx and thyro-hyoid muscle. 3. Branches to the hyo-glossus and surrounding muscles, and to the gustatory branch of the fifth pair. 4. Terminal branches to the geniohyo-glossus muscle.

The London Medical

AND

Surgical Journal.

Saturday, June 17th, 1837.

THE IRISH MEDICAL CHARITIES BILL.

IN a late Number of this Journal we were the first to announce the alarm which was created among the Dublin monopolists, when it reached their deafened ears that it was the intention of Lord Morpeth to introduce a bill for the regulation and support of Public Charities for the Sick Poor of Ireland, and which was to be warmly supported by Mr. O'Connell and the liberal Irish members in the House of Commons. We were fully satisfied that the most strenuous opposition would have been given by the tory monopolizing junta of Irish members in defence of their College of Surgeons, and of their unjust and exclusive possession of the County Infirmary; and though something was to be feared from the presence of the

College Deputation in London, in the persons of Mr. Cusack Roney, Dr. Evan-son, and Mr. Corr, men whose abilities, particularly the former, have been acknowledged to be pre-eminent in Collegiate intrigue, we confess we were totally unprepared for the Meeting of the Members and Licentiates of the Dublin Colleges of Physicians and Surgeons, held on Thursday last, a Report of which will be found in another part of this number. We certainly considered the proposed Bill open to some objections on account of its conciseness; but at the same time we felt convinced that a Liberal Government would protect, as far as possible, the interests of ALL branches of the profession in Ireland; and that whilst the objectionable clauses would have been omitted, or have undergone modifications in committee, other clauses would have been introduced so as to render it a safe and salutary enactment. Notwithstanding the many difficulties which the noble Secretary for Ireland has had to contend against in his endeavours to carry his laudable intentions, we do not fear any new difficulty to present itself to Lord Morpeth in the formidable array which took place at the late Dublin meeting, or in any statements which were made by the different speakers.

It scarcely required the eloquent tongue of Dr. John Crampton to inform the noble Secretary for Ireland, that the Inspectors "should be well educated persons, members of the profession, perfectly independent, and not biassed by party feeling;" much less that his talented and justly distinguished relation, the SURGEON GENERAL, should intimate that the duties of the Inspectors should be defined, or that a man was "lowered" by having an inspector placed over him: and though the Surgeon General, or an individual less eminent in his profession, might justly

complain of the interference of an inspector in the execution of his hospital duties; yet had Mr. Crampton made himself acquainted with the provisions of the Bill, he would have discovered that no such power was to be possessed by the inspectors; but we suppose he received his information from Surgeon Cusack, who has made the extraordinary discovery that "the section of the act for making the inspectors omnipotent over Medical Charities had actually passed," though the bill is not even as yet in committee! The suggestions offered by Dr. O'Beirne must strike every one as being most rational; and we entirely agree with him, that the Poor Law Commissioners are very incompetent to decide on medical matters.

No person could have been better selected than Surgeon Colles to propose the resolution in favour of continuing the *Monopoly* to the Infirmary surgeons, most of whom have been his own apprentices or pupils. He certainly spoke most *feelingly* upon the subject, and it only required his colleague at Steven's, of apprentice *fee* notoriety, Surgeon Cusack, to have seconded the motion, in order to make it fully intelligible to Lord Morpeth. The speech of Surgeon Carmichael accords with his wonted liberality and independence in favour of fairly remunerating the profession; and he gave numerous instances of the paltry remuneration given to those medical practitioners who were so actively engaged in the treatment of that formidable epidemic—the cholera, which struck such terror into all classes of the community. We have long entertained the opinion of Mr. Carmichael that "if the profession had co-operated for their mutual advantage, they never would have been treated by the government of the country in this manner."

This was, however, readily explained

by the Surgeon-General, who had been informed by the government, that there was no necessity of allowing any remuneration while so "many surgeons offered to undertake the duties gratuitously."

The resolution of Dr. Kirby, as to the regulation of education, is at variance with the opinion of the government, and is premature, until Mr. Warborton's bill on that subject, is brought before Parliament.

THE KING'S HEALTH.

(From our Windsor Correspondent.)

The intense interest which has been excited throughout the kingdom relative to the health of the Sovereign, has made me anxious to collect, from day to day, every possible information from such quarters on which implicit reliance could be placed; and there are many circumstances which cannot fail to interest, though they have either been purposely omitted, or distorted for political purposes by the daily press. I formerly stated that though the mucous expectoration had diminished, his Majesty was still afflicted with severe dyspnoea on the slightest movement, which appearances have since continued, and, I regret to add, along with occasional *homoptæ*. Much alarm has been created by these formidable symptoms being combined with a great disturbance in the circulation, the pulse at the wrist being sometimes not even recognizable, and at other times reduced in frequency to a very remarkable degree, leaving no doubt not only of the mucous membrane of the lungs having severely suffered from congestion, but also that a valvular disease exists, the lining membrane of the left side of the heart being in a state of subacute inflammation.

The public have expressed much dissatisfaction in the few bulletins which

have appeared on this lamentable occasion, but they ought to be aware that such documents have been on all former occasions, and probably will ever be, intended not for the purpose of giving any precise account of the malady of the King, but are chiefly concocted to mislead and conceal the real condition of Royal sufferers; and much praise is justly due to the distinguished President of the Royal College of Physicians, for the great skill and consummate knowledge of court etiquette, which he has acquired during a very long experience, by which he has infused into the bulletins that simplicity so universally acknowledged. Besides the names of the celebrated Halford, and renowned Chambers, you will observe that there is appended to two of the bulletins, that also of Sir Matthew Tierney to adorn the composition, and in order to make it still more imposing you have also that of Dr. Davis, our old friend from Kensington.

It has been amusing to us here, who have been long behind the Court scenery, to read the puffings of *Doctor* Davis, who gets the credit of puffing himself, and many of your readers may be curious to know the history of this far-famed and favourite physician of his Majesty, as he is officially announced in the Court Circular. The *Doctor*, when I first knew him, kept a most respectable but very small druggist's shop in Kensington, and his success was such in the "the drug trade that" he repaired to Bushey, where he became an Apothecary of great eminence, and was soon employed to attend the household of the Duke of Clarence. On King William's accession to the throne, the *Doctor* was appointed Apothecary and Medical Attendant in general to his Majesty's household, and his reputation was such, and his professional talents so highly esteemed by the Court, that a few months

since, he received the distinguished honour of procuring a medical degree from the Archbishop of Canterbury—that most Reverend Prelate, never having exerted his privilege of granting degrees in medicine, unless on the most important occasions; for I am not aware that any individuals, except Sir Charles Clarke and our Great Court Physician, Dr. Davis, can in our 'days, claim the high distinction of possessing degrees of such divine origin.

Though no notice has been taken of the professional attendance of Mr. Keate at the Palace, yet I am happy to say, that his Majesty has had all the advantages of his able advice, which, along with the undoubted skill of Dr. Chambers, the King may be said to have had the benefit of the concentrated wisdom of the Solomons of St. George's Hospital. The appointment of Mr. Keate at this moment as an extra Serjeant-Surgeon-in-ordinary, or some such appellation, gives great satisfaction here, and must give general satisfaction to the profession, when it is recollected how shamefully he was excluded from the Court on a former occasion by the nefarious and no less contemptible conduct of certain individuals, who, under the mask of friendship, were base enough to betray his interests. It is but justice to his Majesty, however, to state, that on many occasions he took an opportunity of expressing his deep regret, that he should have been too hastily, and from false representations, induced to neglect Mr. Keate's undoubted claims; so that the precarious condition in which the King's health now is, renders this act of his Majesty, highly honourable to the King's sense of Justice, and cannot fail to be equally gratifying to Mr. Keate.

HOSPITAL FEES SYSTEM.

We have much pleasure in stating that our former account of the intentions of the Gower-street Liberals is confirmed, and that the fee for attendance at the North London Hospital they have finally determined to increase, so as to bring themselves upon a perfect equality with the Old Hospital Cormorants.

MEETING OF THE COLLEGES OF PHYSICIANS AND SURGEONS.

On Thursday last, at four o'clock, a very numerous general meeting of the Fellows, Members, and Licentiates of the Colleges of Physicians and Surgeons, was held at Morrisson's Hotel, "for the purpose of considering the provisions of a bill, now in progress through Parliament, for the better regulation of Hospitals, Dispensaries, and other Medical Charities in Ireland." Dr. Marsh was called to the chair.

Dr. Jacob proposed the first resolution, which was to the effect,—“That it was the opinion of the meeting, that a legislative enactment to provide for the support of Medical Charities in Ireland, and procure the application of the funds to their legitimate objects, was desirable.”

Doctor William Stoker rose to propose an amendment to the resolution, upon the ground that some regulations were necessary for the improvement of abuses.

Dr. Collins suggested that more time should be allowed for the consideration of the resolutions.

Dr. Lendrick concurred in opinion with the gentleman who preceded him.

Dr. O'BEIRNE observed that probably the gentlemen present were not aware that the bill now before Parliament would be read upon the 15th; and, therefore, unless they took immediate steps they would not be able to place the necessary materials in the hands of the Ministers of the crown. (Hear, hear.)

Dr. Brady considered that the gentlemen who were averse to the adjournment had no cause for apprehension, upon the ground of not being in time before legislation, when they took into account the slow rate at which modern legislature was carried on.

After a long discussion, the Chairman put the amendment of Dr. Collins, which

was rejected, and the proceedings were resumed.

The Chairman then put the first resolution to the meeting, and it passed unanimously.

Doctor John Crampton proposed the second resolution, which was to the effect,—“That the establishment of a Board of Inspectors, if composed of well educated, independent, and experienced members of the profession, was calculated to render the charities of Ireland more valuable, and improve the situation of the medical attendants by defining their duties and securing them adequate remuneration.” It was necessary that the inspectors should be well educated persons, of course taking it for granted that they were members of the profession. They should all possess the necessary qualifications entitling them to fill the situations; they should be independent, not biassed by any party feeling, or dependent upon the smiles or frowns of a great man in any part of the country. They should be perfectly independent. The establishment of such a board would render the situations of medical attendants throughout the country much more comfortable than at present, not that he wished to throw any imputation upon them, for he believed them to be a well-educated and a hard-working class of men.

The Surgeon-General considered that the duties of inspectors should be more intelligibly and fully defined. Nothing could be less advantageous to the profession than having inspectors appointed with such duties as the resolution set forth were to be performed by them. Was anything more calculated to lower a medical man than to have an inspector over him? (Hear, hear.) He entirely objected to the practice and principle of inspectors interfering in the least with the treatment and management of a patient who was under the care of a medical practitioner. (Hear, hear.)

Dr. O'Beirne begged to say a few words in reference to the establishment of the Board of Inspectors. The intended constitution of the board was four inspectors—all of them men invested with equal powers—there was neither a head nor a tail to it. He wished to point out a case to show the injury which the board might inflict upon the gentlemen connected with the medical institutions of Ireland. Take the case of an inspector visiting an hospital, and making unfavourable reports of it, and probably unjust recommendations. To whom were the medical officers to ap-

peal? Was it from one inspector to another; or should the case be referred to the case of the superintendent? The Poor Law Commissioners were to possess the control of those inspectors, and those Commissioners were, indeed, very incompetent to decide upon matters which were purely medical.

The Surgeon-General objected to the omission of not specifying and defining the duties of the inspector. For his part he would not act as a medical attendant in any hospital if he were to be interfered with by an inspector.

Surgeon Cusack observed that the section of the act making the inspectors omnipotent over Medical Charities had actually passed.

The Chairman then put the resolution, which was carried with only a few dissentient voices.

The Surgeon-General proposed the third resolution, which was to the effect, that the power to be entrusted to the inspectors was so vague and indefinite, and so liable to misconstruction and arbitrary exercise, that the meeting protested against it.

Dr. W. Stokes seconded the resolution.

Surgeon Colles proposed the fourth resolution, which was in substance as follows:—"That the meeting observed with surprise and regret, that the laws securing payment to the medical attendants of infirmaries, fever hospitals and dispensaries, are about to be repealed without remuneration, and even the 100*l.* a year paid for nearly seventy years to each of the surgeons of the county infirmaries was withdrawn, and applied to the payment of the board of inspectors, which was exceedingly unjust, for those gentlemen were persons of considerable experience and ability." He would observe that it was extremely likely, nay, almost certain, that the enactment, as stated, did not intend to have a retrospective but a prospective tendency, but upon trying to construe the act in that manner, he found it was impossible to give it any other interpretation but this, that the money was to be drawn from the practitioner, and applied to the payment of inspectors (hear, hear). It would be all very just and proper, if the present gentlemen were left undisturbed, to apply the money to the purposes of the board, instead of appointing successors to those gentlemen, but he could not conceive anything more unjust than to withdraw men from their situations who spent years in active service for the good of society. (Hear, hear.)

When they looked to the county infirmaries throughout Ireland, they saw that they were filled by men of the highest education and attainments, who were driven to accept situations in them, because they had not the means of holding out competition in any of the large towns; in fact, they had men of the first qualifications, who, if they were given only a fair field for labour, would be ornaments to the country and the profession. (Hear.) It was unjust to deprive those indefatigable men—many of whom had grown old in the profession, of the salaries which originally induced them to enter upon that profession. He could hardly think it possible that any legislature, with its eyes open, could introduce such a clause. (Hear.)

The Chairman then put the resolution, which passed.

Surgeon Carmichael proposed the fifth resolution, which was to the effect,— "That ample security to remunerate medical officers should be required as an act of public justice, and a necessary security for the members of the profession, and a faithful discharge of their duties towards the poor entrusted to their care." He felt that medical men were worse rewarded for the public duties they had to perform than any body of men in the community. (Hear.) In fact, it appeared to him that government, upon all occasions, evinced the greatest disparagement and even contempt towards medical men, and he congratulated the profession upon the meeting they held that day, which he hoped would be the *nucleus* around which medical men might combine and protect themselves in future. As instances of his assertion that government disregarded their interests, he would mention the attempt to introduce the Grand Jury Bill of last session, which was withdrawn solely in consequence of the co-operation and combination of medical men, who objected to its provisions. (Hear, hear, hear.) They also saw what attempts were made to disparage medical men, by the extinction of every office of honour or emolument attached to the profession; for instance, the situation of Surgeon and Physician-general; that of State Surgeon and Physician, and even the paltry salaries which the Surgeons of the House of Industry had always enjoyed were withdrawn. (Hear, hear.) If the professions had co-operated for their mutual advantage, they never would have been treated by the government of the country in this manner. (Hear, hear, hear.) We should

also recollect another instance. At the time the cholera raged, a number of medical men were sent from Dublin to attend to the afflicted. At the very same period a number of young lawyers were employed to forward the registries. The former, for immense labour and imminent risk of life, had from one to two pounds a-day doled out to them by the government; while the latter, for their comparatively trifling occupation, enjoyed the handsome payment of five guineas per day. (Hear, hear, hear.) Are medical men of an inferior rank of life, or are they worse than, lawyers? (Hear.) No, but they have no *esprit de corps* to preserve them from degradation, and instead of combining for their mutual support, they are eternally undermining and underselling each other. (Hear.) He, however, hailed the appointment of medical inspectors because he considered that the profession would thus be brought into closer contact with the government. (Hear.) He trusted, however, that they would be well paid, for no man of ability and education would undertake the office unless he was well paid. If uneducated and inexperienced persons, who would be satisfied with trifling incomes, were appointed, the system of inspection would be more a bane than a boon to the profession and the country. (Hear.)

Dr. Montgomery seconded the resolution.

The Surgeon-General said, he wished to answer the inquiry, in some degree, why medical men were undervalued by the government? When the question of taking the salaries from the officers of the House of Industry was first discussed, he was spoken to upon the subject by the Chief Secretary of the day, and every argument which he (the Surgeon-General) could use to impress upon him the monstrous injustice of forcing medical men to perform such duties, and then leave them to find a reward for their exertions solely in the consciousness of having discharged their duties was resorted to by him. (Hear, hear, hear.) But the answer given to him by the Chief Secretary, indeed by every Chief Secretary, was, that there was upon his table bundles of letters from members of his (the Surgeon-General's) own profession, offering to undertake the duties gratuitously. (Shame, shame.) He (the Surgeon-General) read these letters; of course it would not be proper for him to mention any names. Another answer to every argument in favour of the profession was,

that in England no remuneration for such services was required, and Guy's and Bartholomew's Hospitals were instanced in confirmation of the assertion. To be sure there was to this objection a very satisfactory answer—namely, that there were schools attached to the hospitals cited, which produced from £1,500 to £2,000 per annum, and a physician or surgeon could very well afford to attend them gratuitously, when such emoluments were to be procured from the schools; but in Ireland the case was quite different. (Hear, hear.)

Surgeon Carmichael observed, that if there were a regular central board, an opportunity would be afforded the profession, as in the case of the bar, to expose any violation of their laws. (Hear, hear.)

Dr. Kirby proposed the sixth resolution—namely, "That every well educated member of the college of physicians was eligible to be appointed to an infirmary, hospital, or dispensary, but it was necessary that a clause should be introduced defining the period of his education, and the nature and extent of his qualifications, and that unless such clause was introduced, or a bill containing such a provision was brought forward, any alteration in the present law protecting the poor must be considered premature, impolitic, and unjust."

After some discussion, the Chairman put the resolution, which was adopted.

Surgeon Colles was then called to the chair, and the usual vote of thanks having been passed to Dr. Marsh, the meeting separated.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

May 23, 1837.—DR. BRIGHT, President.

Nervous affections peculiar to young women, causing contraction of the muscles of the extremities, accompanied by increase, diminution, or absence, of sensation, or motion.

Dr. John Wilson, physician to the Middlesex Hospital, in a paper under the above title, read this evening, briefly details the circumstances of ten cases of nervous affections occurring in his practice at the hospital, the subjects of which were all young women, and, with one exception, single. The symptoms in these cases varied exceedingly; in some, simulating disease of the hip and spine, occasionally attended with common hyste-

rical features, occasionally with paralysis of one or other of the limbs, hemiplegia, rigid muscular contractions, and other evidence of extreme nervous affections; generally, but not invariably, the uterine functions were disordered, and the bowels were usually constipated. The treatment consisted in the administration of purgatives by the stomach, as well as in enemata; in the use of acupuncture, the cold shower and douche-baths, large doses of carbonate of iron, and other local and general means, which succeeded, usually in a very short time, in giving entire relief to these distressing affections. The remedy, however, which was productive of the most decided advantage, was forcible extension of the contracted limbs, by obliging the patients to stand unassisted by the sound limbs, and causing them to walk, with assistance, about the ward. These means the author found it often very difficult to enforce, owing to the objections of the patients, and the sympathies excited in the nurses and other beholders, by the apparent severity of the treatment. The author satisfies himself with relating the cases briefly to the Society, leaving it to others to form their own conclusions from them.

Dr. Bright said, that the cases related by the author of the paper were interesting, and advanced some new plans of treating hysterical affections of a severe character which were worthy of the consideration of the Society. How far were the needles beneficial in the instances in which they were employed? He had seen a case in which recovery took place without their application. A young woman had been seized suddenly with loss of sensation and motion in her right hand, as far up as the wrist joint. She was in the habit of getting up in the day-time to sit by the fire. One day she was seized with paralysis of the right leg, and could not get to bed without assistance. She gradually recovered the use of her right hand, and, subsequently, of her leg, the only remedial means employed likely to produce such a result being the application of a few blisters to the spine.

Dr. Johnson said, that the cases of Dr. Wilson proved that hysterical affections, particularly in young women, might simulate organic disease occurring in every part, from the head to the foot, even taking on the character of white swelling, loss of vision, &c. He thought the author had acted wisely in advancing no theory on the subject; the idea of the uterus wandering from one part of the body to

another, was a good as any that had been adduced. There were two points of importance respecting these affections; one was, how to distinguish them from real organic diseases; and secondly, how to treat them best. They were, no doubt, frequently treated erroneously by young practitioners, who supposed that they were organic diseases, and proceeded accordingly, with very active remedies. The patients might get well, and it was thought organic disease had been cured. In determining the nature of the disease, he (Dr. J.) only knew two diagnostic marks of the occasional presence of hysterical symptoms, and the health not being affected to the degree generally found in organic disease; the vital functions going on very naturally during the presence of the most formidable symptoms. Respecting the treatment, it had been powerful in these cases, and, indeed, was often so, various remedies being employed without effect, till time cured the affection, the last remedy employed getting all the credit. Solitary confinement in a black hole was a more effectual means of treatment than any other. Time, he thought, the only remedy in these affections.

Dr. Weatherhead could not agree with the last observation. Many remedies were of great value in hysteria, particularly assafoetida, carminative tinctures, and aromatic bitters, these relieving the flatulences of the stomach and bowels, to which hysterical patients were subject to a distressing extent. He could not understand why some practitioners employed such large doses of carbonate of iron in these affections, for that medicine being insoluble, could not act until it had been decomposed in the stomach or bowels. The muriatic or acetic acid, were the only two present to effect this change. Would it not be more direct to administer the muriated tincture, or the acetate of iron? The only reason he could see for using the carbonate was the fact of its lodging in the bowels, and becoming gradually decomposed, and so exerting its efficacy.

Dr. Webster thought that aloetic purgatives, combined with steel, were very useful. He considered a little severity to be beneficial; the cold douche was also a valuable remedy.

Dr. Moore thought, from the sympathy which existed between the cerebellum and the uterus, that hysterical symptoms would generally be relieved by cupping, and the application of cold to the former.

Mr. B. Phillips related the following

remarkable case, shewing the inefficacy of all kinds of remedies, in some instances:—A young woman, aged 20, was in good health, when she received a very slight injury, to which her subsequent illness was referred. One day, whilst ironing, she struck herself an considerable blow at the lower end of the radius, just where the radial nerve passes along. The contusion was very slight, but the part swelled, and she complained of very acute pain; which gradually getting worse for the space of a fortnight, he (Mr. P.) was requested to see her. He found little appearance of the injury on the part, but there was much tenderness, which increased on pressure. He ordered leeches to be applied. Two days afterwards there was a little spasm of the surrounding muscles, and incipient contraction of the fingers, which proceeded gradually to the most perfect contraction. She suffered from excruciating pain, which advanced towards the head; cupping and blisters were applied to the back of the head without effect. The contraction extended from the fingers to the wrist-joint, and subsequently to the elbow; in the space of three weeks from the time he first saw her, the vision of the left eye became first imperfect, and was afterwards entirely lost. She suffered great pain, and had severe spasmodic action of the muscles, occurring in paroxysms fifteen or twenty times a day, and always proceeding from the injured point. During all this time her bowels were open and her catamenia regular. Counter-irritation applied to the back of the head afforded her no relief; large doses of tincture of opium and hydrocyanic acid were of no benefit; and she went on in this way for three or four months. At a consultation of several physicians and surgeons at the end of this period, various plans of treatment were suggested—excision of a portion of the radial nerve, amputation of the radius, &c. One of the physicians recommended colwobs to be taken; these were used for a week, and sulphate of iron for three or four weeks afterwards, without any effect. At the last consultation it was determined to leave the case to itself; the health was still unimpaired. At the end of three weeks, having been living on good diet, the patient was better, and, in twelve or thirteen weeks, quite well.

Dr. J. Johnson said, that when he spoke of the inutility of medicine in hysteria, it was the anomalous and puzzling forms of the affection, like the last that

was related, common hysteria, many remedies were efficacious.

Mr. Arnott said that the diagnosis in cases of hysteria simulating diseases of the joints was often very difficult to form, particularly in cases where the symptoms followed a slight injury. He thought the general appearance of the patient, and the continuance of good health, a good diagnostic mark. There was, also, seldom much swelling; he had never seen anything like a "white swelling," the tumefaction being always much more limited than in that disease. In cases where the knee-joint was affected from hysteria, the patient complained of pain on motion, and when the ends of the bones were rubbed together, but then the slightest touch of the skin, before the deeper-seated parts were at all pressed upon, produced great pain. The surface, too, was seldom preternaturally hot. Hysterical symptoms were not always present, and the great point was to wait. He had seen a case occurring in the ankle, in which there was pain, and inability to move the joint. In this instance there was pain in the left side, a frequent symptom in hysteria. In hysterical affections of the hip-joint, the limb, though apparently shortened, was not really so, which would be ascertained on a careful and accurate admeasurement. If the patient's mind was kept engaged for the time, pushing the head of the bone against the upper part of the joint produced no pain. Moral treatment was of great effect in hysterical cases. He agreed as to the efficacy of Dr. Wilson's treatment. In the case of the ankle-joint he (Mr. A.) had alluded to, the use of the needles did good. He had seen the cold douche effectual in cases of contraction attended with great pain. In one case in which tetanic spasms attacked the limb, and in which two and three grain doses of morphia were given without benefit, the cold douche immediately relieved both pain and spasm.

The President, on retiring, said, that in the ordinary course of things, this was the last meeting of the Session; but in consequence of several valuable papers being still unread, an extraordinary meeting would take place on Tuesday, the 13th of June. He again mentioned the dilatoriness of members in forwarding their communications, which caused much inconvenience.

MEDICAL CHARITIES.

(IRELAND.)

(*Concluded from page 314.*)

And be it enacted, That it shall and may be lawful to and for all bodies politic and corporate, trustees, guardians of infants, committees of lunatics, femes covert, with their husbands, and all other persons whatsoever who are or shall be seized or possessed of or interested in or entitled to any estate or interest whatsoever in the lauds, houses, grounds, tenements, buildings or hereditaments, which by the said Medical Inspectors shall be thought necessary to be rented or purchased for any of the purposes of this Act, by deeds indented and enrolled, to demise, sell and convey all and any such grounds, houses, tenements, or hereditaments, or any part thereof, and all the respective estates and interest therein, to the said Inspectors, or any *Two* of them, and their heirs and successors, and that all contracts, agreements, bargains, sales and conveyances that shall be so made, shall be good and valid in law to all intents and purposes whatsoever; and that such Medical Inspectors for the time being, and their heirs and successors, shall be trustees of all such houses, lands, tenements and hereditaments, as shall be conveyed to, or vested in, them, under and by virtue of this Act, for the purposes herein provided, and for no other purpose whatever.

And be it enacted, That all and every of the provisions of an Act passed in the fiftieth year of the reign of King George the Third, intituled, "An Act for repealing the several Laws relating to Prisons in Ireland, and for re-enacting such of the Provisions thereof as have been found useful, with Amendments;" or any Act for amending the same, which affect or relate to the purchase, holding a court and valuation of lands, tenements or hereditaments, for the sites of gaols or prisons, or to any notices, proceedings, summonses, verdicts and judgments, or to any conveyances or enrolments, or to the lodgments of consideration-money, or to petitions to the High Court of Chancery in Ireland, or to any payments of purchase-money, or to any rights and titles of parties interested, shall be held to apply to the valuation of lands, tenements or hereditaments rented or taken for the purchase of land under the provisions of this Act, and such verdicts, judgments and conveyances shall be binding and conclusive to all intents and purposes whatsoever,

and that all the powers vested in the Commissioners by said Act, or of any Act for amending the same, shall be and are hereby vested in the said Medical Inspectors, or any *Two* of them, for the purpose of the valuation of all lands, tenements and hereditaments, for the purposes of this Act.

And be it enacted, That from and after the *passing of this Act* it shall and may be lawful to and for every Archbishop, Bishop, Dean, Dean and Chapter, Archdeacon, Dignitary or Prebendary, to grant, by his or their deed or deeds respectively, any piece or parcel of land, not exceeding *Six* Acres plantation measure, as and for the site of a Hospital, Asylum or Dispensary, in such and the like manner as such Archbishop, Bishop, Dean, Dean and Chapter, Archdeacon, Dignitary or Prebendary, is empowered to do with respect to land for the site of a church and churchyard, in and by an Act passed in the Parliament of Ireland in the thirty-third year of the reign of King George the Second, among other things to encourage the building of new churches: Provided always, That such grant shall and may be made either to the churchwardens of the parish in which said land shall be situate, and their successors for ever, according to the directions of the said Act of the thirty-third year of King George the Second, or to the said Medical Inspectors, as the Lord Lieutenant or other Chief Governor or Governors of Ireland shall order and direct; and such grant shall be good and effectual against such Archbishop, Bishop, Dean, Dean and Chapter, Archdeacon, Dignitary or Prebendary, and his and their successor and successors; and the churchwardens of such parish and their successors for ever, or such Inspectors as aforesaid, and their heirs and successors, shall be and are hereby empowered and made capable of receiving and enjoying the benefit of any such grant, for the purpose aforesaid, in like manner as by the said Acts, or either of them, is provided with respect to any land granted for the site of a church and churchyard or lunatic asylum respectively.

And be it enacted, That it shall and may be lawful for any body corporate or collegiate, civil or ecclesiastical, aggregate or sole, to demise or lease any lands within the kingdom of Ireland to the Governors, Trustees or other proper officers of any Public Hospital or Hospitals within the said kingdom, for the use of such Hospital or Hospitals, or for form-

ing a Cemetery to belong thereto, for any term of years, or for life or lives certain, or lives renewable, at the best yearly rent that can then be obtained for the same, and subject to such covenants, conditions, and provisions as shall be agreed upon between the said lessors and lessees; and in every such lease there shall be a reserved power of re-entry on non-payment of the rent reserved within a reasonable time after the same shall become due and payable; and every such lease shall be good, valid and effectual against every person having or claiming to have any charge or incumbrance affecting either in law or equity the funds or premises comprised therein: Provided always, That no such lease shall demise a greater quantity than *Thirty Acres*, and that no fine shall be taken or received for making any such lease or demise, or on any renewal thereof.

And be it enacted, That it shall and may be lawful for the said Lord High Treasurer or Commissioners of His Majesty's Treasury to order and direct that any sum or sums of money shall be advanced and issued and paid out of the growing produce of the said Consolidated Fund to such person or persons as shall be named in any such order, or into the Bank of Ireland in the names of any such person or persons, to be paid and applied for the purpose of erecting and establishing any such Institution for the poor in any such district in Ireland, in such sums and at such times, and in such manner and proportions, and under such rules, regulations, terms and conditions, and to annex such penalties for breach of such rules, regulations, terms and conditions, as to the Lord Lieutenant or other Chief Governor and Governors of Ireland shall seem best suited for promoting the beneficial purposes of this Act.

And be it enacted, That it shall be lawful for the Grand Jury of any and every county, county of a city, or county of a town in Ireland, in or for which, either wholly or in part, any such Institution hath been or shall be erected; and such Grand Jury are hereby required, at the assizes next after the date of any such order for the advance of money for the erecting, opening, carrying on or maintaining any such Institution, or as soon after as they shall be thereto required, and from time to time, whenever the case shall happen, to make presentment for the raising off any such county, county of a city, or county of a town, and without the same having been previously submitted to the special sessions, such sum or sums

of money as shall be necessary for the repayment of any such sum or sums of money so advanced, or any part thereof, at such times and in such proportions as shall be directed and ascertained by any order or orders to be made by the Lord Lieutenant, or other Chief Governor or Governors of Ireland: Provided always, that all houses and buildings adjoining to any city or town in Ireland, and considered as part of such city or town, shall be liable to be assessed for such presentments under the provisions of this Act, as if such houses or buildings were within such city or town, notwithstanding any local or other Act to the contrary.

And be it enacted, That if any such Grand Jury shall neglect or refuse to make any such presentment, the Judge of Assize shall and may and is hereby required to order the sum or sums which ought to be so presented to be raised as if the same had been so presented, and the same shall be raised and paid accordingly: Provided always, That the Certificate of the Chief Secretary or Under Secretary for Ireland shall be sufficient evidence of the advance of money and order of the Lord Lieutenant or other Chief Governor or Governors of Ireland upon which the several Grand Juries and Judges of Assizes shall make such presentment.

And be it enacted, That whenever a Poor Rate is established in Ireland under the provisions of any Act to be passed for the relief of the destitute Poor in Ireland, and in course of collection throughout Ireland, the sums to be advanced by order of the Lord Lieutenant or other Chief Governor or Governors of Ireland as aforesaid shall be paid out of such Poor Rate, and that from thenceforth the power of Grand Juries to present for same shall cease and determine.

And be it enacted, That the sum paid annually to the Treasurer of the Hospitals and Infirmarys out of the Consolidated Fund in Ireland, under the provisions of an Act passed in the fifth and sixth years of the reign of King George the Third, intitled, "An Act for erecting and establishing Public Infirmarys or Hospitals in this Kingdom." shall in future be paid and applied towards the salary and expenses of the Medical Inspectors and Medical Charity office in Ireland.

And be it further enacted, That all fines and penalties imposed by any Act now in force in Ireland, or any fines or penalties imposed upon any person by any Court of Justice in Ireland, shall be ap-

plied to the benefit of the Infirmary of the county, county of a city or town in which the offence for which such fine or penalty has been inflicted shall have been committed.

And be it enacted, That this Act may be altered, amended or repealed in this present Session of Parliament.

**ACCOUNT OF A MAN
WHO WAS
BURIED ALIVE FOR A MONTH,
AND THEN
EXHUMED ALIVE.**

*By H. M. TWEDELL, Esq., Bancoorah,
East Indies.*

The improbability of an act is not to be taken as conclusive against its possibility. There seems to be no bounds to man's ingenuity, or artifice. Circumstances which appear unaccountable to the wise men of the present day, may be familiar to forthcoming philosophers of the twentieth century. The exploits of the salamander lady, of the fire king, of the woman who supported a huge anvil on her chest, of those who in their mouth hold molton lead, and wholesale digesters of poisons, may appear as bagatelles in comparison with the accomplishments of our posterity. Even the account furnished in this paper may be only interesting to future philosophers as the first of a series, showing, that air, food, and water, are not entirely necessary to sustain existence, and that a man may betake himself to the grave, and pass away a month, comfortably, if assured that a shovel will be exerted to release him at the appointed hour.

The facts detailed in this account were communicated to me, within these few days, by Lieut. A. H. Boileau, of the Engineers, first assistant Great Trigonometrical survey, who at that time was employed in the survey of that part of the country. For the sake of accuracy, he consented to my taking a copy of a letter written by him to his family on the day that the buried man was resuscitated. That letter I here have permission to publish :—

“I have just witnessed a singular circumstance, of which I had heard during our stay at this place, but said nothing about before, the time for its accomplishment not being completed : this morning, however, a man who had been buried a month, on the bank of a tank, near our

camp, was dug out alive, in the presence of Esur Lal, one of the ministers of the Muharâwul of Jaisulmer, on whose account this singular individual voluntarily was interred a month ago. He is a youngish man, about thirty years of age, and his native village is within five kos of Keruaul; but he generally travels about the country to Ajmeer, Kotah, Endor, &c., and allows himself to be buried for weeks, or months, by any person who will pay him handsomely for the same. In the present instance, the Râwul put this singular body in requisition, under the hope of obtaining an heir to his throne, and whether the remedy is efficacious or not, it deserves to be known. The man is said, by long practice, to have acquired the art of holding his breath by shutting the mouth, and stopping the interior opening of the nostrils with his tongue; he also abstains from solid food for some days previous to his interment, so that he may not be inconvenienced by the contents of his stomach, while put up in his narrow grave; and he is sewn up in a bag of cloth, and the cell is lined with masonry, and floored with cloth, that the white ants and other insects may not molest him. He was buried at Jaisulmer, in a small building about twelve feet by eight, built of stone; in the floor was a hole three feet long, two and a half feet wide, and perhaps a yard deep, in which he was placed, in a sitting posture, sewed up in his shroud, with his feet (or legs) turned inwards towards the stomach, and his hands also pointed inwards towards the chest. Two heavy slabs of stone, six feet long, several inches thick, and broad enough to cover the mouth of the grave, so that he could not escape, were then placed over him, and I believe a little earth was plastered over the whole, so as to make the surface of the grave smooth and compact. The door of the house was also built up, and people were placed outside that no tricks might be played. At the expiration of a full month, that is to say, this morning, the walling up of the door was broken, and the buried man dug out of the grave, the moonshee belonging to Captain Trevelyan, of the Bombay Artillery, only getting there in time to see the ripping open of the bag in which the man had been enclosed. He was perfectly senseless, his eyes were closed, his hands cramped and powerless; his stomach shrunk very much; and his teeth jammed so fast together, that they were forced to open his mouth with an iron instrument, to pour a little water down

his throat. He gradually recovered his senses, and the use of his limbs, and when we went to see him, was sitting up, supported by two men, and conversed with a low, gentle tone of voice, saying, "that we might bury him again for a twelvemonth if we pleased." He told Major Spiers, at Ajmeer, of his powers, but was laughed at as an impostor; but Cornet (now Lieut.) Macnaghten, of the 5th regt. Light Cavalry, assistant to the agent to the Governor-Gen. ing Ragpootanah, put his abstinence to the test at Pokhur, by suspending him for thirteen days, shut up in a wooden chest, which, he says, is better than being buried underground, because the box, when hung from the ceiling, is open to inspection, on all sides, and the white ants, &c. can be easier prevented from getting at his body, while he thus remains insensible. His powers of abstinence must be wonderful; nor does his hair grow during the time he remains buried. I really believe that there is no imposture in the case, and that the whole proceeding is actually conducted in the way mentioned above."

Lieut. Boileau was unacquainted with the man's name or caste; he told me that he believed he had taken up the life of a Fakeer. He understood that the man had been buried six or seven times, but whether for any period longer than a month, he knew not; he did not hear how the man discovered his powers, or when he commenced to practice them. Lieut. Boileau arrived at Jaisulmer, after the interment, and saw the place described in his letter, in which the man was buried. There was a guard of four or five Chuprases, in the employ of Maharawul, as he understood, who were on the watch to prevent any interference or imposition. The process of burying and of disinterment was conducted in the presence of Esur Lall, one of the ministers of muharawul. The day fixed for the disinterment was known to Lieut. Boileau. Captain Trevelyan's moonshee, who had set forth to give intelligence when operations were to be commenced, arrived only in time to see the people ripping open the cloth, or shroud, in which he had been enclosed. The moonshee immediately started off a man to inform his master, and Lieut. Boileau, who were in their tents, at a distance of about three furlongs.

They repaired to the spot as quickly as possible. Perhaps a quarter of an hour had elapsed, since the opening of the grave, before they arrived. The people had thrown a clean cloth over the man;

two of them supported him; he presented an appearance of extreme emaciation and debility; but weak as he was, his spirit was good, and his confidence in his powers unabated. Lieut. Boileau examined, and measured with his walking-stick, the grave in the floor, and also the two slabs of stone which had covered its mouth. For seven days preceding the burial the man lived entirely upon milk, regulating the quantity so as to sustain life, whilst nothing remained to give employment to the excretory organs. In that state he was buried. He had great dread of the white ants. Several folds of cloth were spread on the bottom of the grave, to protect him from their attacks. On taking nourishment after his release, he is said to be in a state of anxiety, until he has ascertained that the powers of his stomach and intestines are not impaired. Lieut. Boileau saw nothing more of the man; he understood that he regained his strength, and was for some time in attendance at the durbar of the Maharawul, in the hope of receiving his promised reward, and that, tired of waiting until the purse-strings of his patron were loosened, he had stolen a camel and decamped.

The following passages occurs in "Notices of Brazil in 1828-29," by the Rev. R. Walsh, LL.D., in speaking of the foreign slave trade:—"The wretched slaves often inflict death upon themselves in an extraordinary manner. They bury their tongues in the throat in such a way as to produce suffocation. A friend of mine was passing when a slave was tied up and flogged; after a few lashes he hung his head, appearing lifeless; and when taken down, was actually dead; his tongue was found wedged in the œsophagus, so as completely to close the trachea. The slave who by this action of his tongue provokes death, hitherto has been supposed to be dead, and in many instances perhaps without any examination at all, his body has been consigned to the grave."

There is a case published by Dr. Cheyne, of a man who had the power of suspending his animal functions, and who performed the experiment *once too often*.

It may be supposed that the public notice of the extraordinary powers of this man will attract the attention of physiologists in both hemispheres

All communications and works for review to be forwarded, (carriage paid) to Dr. RYAN, 4, Charlotte-street, Bloom's bury-square.

(7.) *Calculi.*—Calculi are of various kinds:—1. Vesical. 2. Renal. 3. Bronchial. 4. Salivary. 5. Biliary. 6. Bursal. 7. Intestinal. Bronchial calculi consist of phosphate of lime; and occur chiefly in those who work in dusty places. Intestinal calculi are often composed of magnesia; and hence they are not proper calculi, not being the result of inflammation, but being formed from the ingesta. They occur chiefly in the duodenum. They sometimes consist of phosphate of lime, with a little animal matter; and when they occur in the lower animals, are called bezoards. Sometimes they contain hairs, or are formed round the indigestible ear of an oat, or round a piece of cabbage-stalk. Intestinal calculi consist occasionally of concrete mucus, or fat, or biliary calculi.

Biliary calculi are formed of cholesterine; or resin, or mucus, or inspissated bile. They are lighter than water; are soluble in oil of turpentine, ether, and alcohol, and are fusible and inflammable. Munro speaks of a black kind of biliary calculi, heavier than water. The latter probably consist of bile very much inspissated.

The vesical calculi are lithic acid, lithate of ammonia, phosphate of lime,

phosphate of ammonia and magnesia, oxalate of lime, carbonate of lime, silica, cystic oxide, xanthic oxide, and fibrin. The combustible calculi are the animal, the incombustible are the mineral. 1. Lithic, or uric acid calculus, is of a yellowish brown colour; smooth, small, and laminated. It is soluble in a solution of potash; insoluble in water, acids, and alcohol, and burns away before the blow-pipe, with a fetid odour. If acted on by nitric acid, it becomes a purpurate of ammonia. If it form an alternating calculus with phosphate of lime, the lithic acid is always internal. 2. Lithate of ammonia is white and laminated; insoluble in alkaline solutions, but soluble in nitric and muriatic acids, but not in sulphuric. It is not affected by the blow-pipe. Lithate or ammonia is said not to form calculi, though it often appears as a deposit in the urine. 3. Phosphate of lime is the most common calculi in children when ossification is going on. 4. Phosphate of ammonia and magnesia. If this calculus be put into a solution of potash, ammonia is given off, magnesia is precipitated, and phosphate of potash remains in solution. It is large, white, and crumbling; and soluble in acetic acid. Mixed with the last mentioned calculus (phosphate of lime) it forms the fusible calculus. 5. Oxalate of lime form the mulberry calculus, or, if small, the hemp-seed calculus. It is not decomposed either by acids or alkalis, but it is soluble in nitric acid. If exposed to the blow-pipe, oxalic acid is driven off. This calculus, together with uric acid and cystic oxide, are the only primary calculi, so called because formed in the kidney, and finding their way into the bladder through the ureter. 6. Carbonate of lime often occurs as a calculus in the lower animals, but has been described as occurring in the human subject only by Crampton. It effervesces with all the acids except the uric. 7. Silica. Very rare as a calculus. 8. Cystic oxide calculus was described by Wollaston. 9. Xanthic oxide is Marcet's calculus. It is acted on by weak acids and boiling water; which the cystic oxide is not. It likewise becomes of a lemon-colour if exposed to nitric acid. 11. The Fibrinous calculus is elastic, and gives off nitrogen if exposed to action of nitric acid.

Bursal calculi are composed of urate of soda and urate of lime, and are soluble in boiling water, which very few of the other calculi are. It is probable that calculi do not arise from vitiation of the blood, but from vitiated secretions—the result of in-

flammation. Biliary, bronchial, and gouty calculi, unquestionably are so, and so probably are all the rest.

S. Depositions of Natural Fluids in Excess.—Increased deposition of any fluid of the body may take place—whether it be a perspirable, a follicular, or a glandular secretion. The mucus which flows in increased quantity from the nostrils in catarrh, is at first thin, acid, and saline; but towards the end of the disease it is thick and mucilaginous. In hydrophobia the saliva is said to be contagious. Pyrosis is probably typhalism of the pancreas. Glandular secretions are sometimes diminished in quantity, and at other times increased, by inflammation of their respective glands. This arises from the different part of the gland which is affected by the inflammation. Thus the difference between hepatitis and cholera, and between nephritis and diabetes, is, that in the former, inflammation is seated in the ducts of the liver and kidneys respectively, while in the latter the inflammation is in the radicles. Hence the secretion of bile and of urine is suppressed in hepatitis and nephritis, while it is increased in cholera and diabetes.

After asthma, diabetes, and hysteria, the urine has but few of its characteristic principles, but is loaded with them in gout, rheumatism, catarrh, the hot stage of fever, and in hectic. It is heavier than usual in diabetes, and lighter in dropsy; and in the latter contains much mucus.

5. Depositions of Preternatural Fluids—These comprehend dropsies and hæmorrhagies of various kinds; collections of air and collections of pus. Under the head of each we shall notice their characters, and the various opinions respecting their origins.

(1.) *Dropsy.*—It was an old notion, that dropsy was either active or passive, the former being the result of inflammation, or increased action, and the latter of debility, or diminished action. But dropsy is always the result of inflammation, being the increased halitus of the inflamed surfaces; just like the increased secretion of mucus in catarrh. This halitus, too, is vitiated, which it would not be if dropsy were a mere effusion, and, beside, the preceding symptoms of inflammation are often well marked. This doctrine is supported by Parry, Grappengreiss, Rush, Blackall, Ayr, Abercrombie, Frank, Hoffman and others.

Dropsy cannot be from diminished absorption, for absorption is rapid in dropsy.

Why should the absorbing vessels refuse to take up the dropsical fluid, while they take up other matters very readily; such as mercury rubbed into the thighs? It is true that dropsy may be produced by obstructing the veins, but this does not prove that dropsy arises from diminished absorption, for by this obstruction the capillaries must be overloaded, and this will give rise to increased secretion. Increased arterial action alone would not produce dropsy. It would push the blood into the veins, but would not cause effusion. It is not from debility, for there is often much debility without dropsy. Dropsical fluid is generally coagulable by heat; but the fluid of hydrocephalus is usually an exception to this rule. There are often shreds of coagulable lymph floating in it.

You may be surprised at my placing rickets among the dropsies; many of those who have paid most attention to the subject, attribute it to increased deposition of fluid of some kind. An extensive assortment of theories, chiefly chemical, has been proposed on the subject. All analogy is against the supposition of defective deposition, and we must therefore ascribe it to increased absorption. Phosphate of lime has been found in the lymphatics in such cases. The cellular tissue of the bones must be liable to increased deposition of fluid, as well as the cellular tissue elsewhere; and this increased quantity of fluid must produce pressure, and increased absorption. The bones in rickets are soft and red. What could be a stronger evidence of inflammation, and what a more natural termination of this inflammation, than a deposition of fluid? This is the opinion of Boyer, Beclard, and Howship; and I adopt it from its consistency with analogy, which I think must be our guide here.

The ulcer which takes place at the ankle, in cases of varix of the saphena vein, is from a major degree of inflammation from pressure, for the ulcer was preceded by œdema. Blackall says that dropsy is frequently the result of inflammation, and Hare, that it is always so. Carmichael Smyth advocates the opposite view of the case, and attributes hydrocephalus to debility. But now that inflammation is thought to be diminished, instead of increased, action, it amounts to the same thing as debility. The question is, whether in hydrocephalus we have the fever which attends inflammation or not? The question whether the increased fluid is the result of secretion or of exudation, is

not a mere dispute about words, for it amounts to the question whether this effusion is active or passive, or whether it is the result of inflammation or not. Smyth advocates the negative side of the question. Dropsies, however, are not a mere exudation of serum, for the effused fluid often differs from serum. I should think that every termination of inflammation is regulated by a diathesis, which is dependent on the constitution of the individual, and that scrofula is no more hereditary than hæmorrhage, as a termination of inflammation, though it is more remarkable. Vesicles are dropsies in the skin, and bullæ are dropsies on its surface.

(2.) *Hæmorrhage*.—Hæmorrhage is analogous to dropsy, as is seen in pulmonary apoplexy, blind piles, chemosis, sanguineous apoplexy, hæmæthorax, hæmatocele, and purpura hæmorrhagica. Blood is often discharged by the natural outlets of the body. Coagulable lymph contains within itself the rudiments of organization, but blood does not, and therefore when the latter is extravasated it is never organized, but becomes surrounded by a cyst.

The menstrual secretion sometimes degenerates into hæmorrhage; but what is inflammation at first, must be inflammation throughout. If menstruation were mere effusion, there would be no preceding febrile symptoms, such as do attend it. Sudden and copious epistaxis does not prove that a rupture of some blood-vessel must have taken place; for the lachrymal gland will speedily secrete a very great quantity of tears; and there is no pretence of rupture here. The flow of blood in epistaxis, is much more likely to be from secretion, than from the rupture of a few vessels so minute, that they cannot afterwards be discovered. Even in apoplexy, Abercrombie and Cheyne have looked in vain for ruptured vessels. What are the premonitory symptoms of apoplexy, but the symptoms of encephalitis? Some of the early pathologists used to speak of a power in the blood itself, overcoming the resistance of its vessels; and sometimes the latter giving way from putrefaction. It is quite time to discard the cant about "breaking a vessel," or "bursting a vessel," or a copious hæmorrhage from large vessels, and a hæmorrhage from small vessels; or about tying ligatures round the limbs, to prevent the blood from going to the lungs. The division, likewise, of hæmorrhages into active and passive, or into those which come from the arteries and those which

are furnished by the veins, is quite unfounded.

(3.) *Collections of Air*.—Hunter showed that air might be secreted from the arteries; and Baillie, that it was the result of inflammation. Davy found that the air in the intestinal canal was composed of oxygen and nitrogen in the upper part, and of nitrogen in the lower. Air sometimes is produced in situations where there is nothing to ferment, as in the arterens, peritoneum, and pleura.

(4.) *Collections of pus*. Suppuration was thought by Hippocrates to be a melting of the solids; and by Boerhaave and Cullen to be an effusion of vitiated serum. De Haen and Morgan proved that pus is a secretion. It is heavier than water, globular, opaque, and cream-coloured; has a disagreeable odour, especially if thrown on burning coals, but not if kept from the air. Mucous is distinguished from it by being lighter than water, translucent, of a stinging consistence, and destitute of odour. It is not soluble in water to potash, which pus is. Darwin's test is to put them into sulphuric acid, and to add water. The pus descends while the mucus ascends. Hunter's test is muriate of ammonia, which dissolves pus, but not mucus. Young says that if placed between two pieces of glass and held before the candle, the pus will appear to have a halo round it.

Pus is one of the only four fluids in the body which contain fibrin. The others are blood, lymph, and chyle. Pus coagulates spontaneously and is easily miscible in water. It used to be said that the use was to defend the parts it covered from air, to soften the flesh, &c. It is probably to granulations, what coagulable lymph is to adhesions, containing in itself the rudiments of their formation. Sir Everard Home says that carbonic acid exists in pus as well as in coagulable lymph.

Sanies is an impure kind of pus; thin, brown, acrid, and not coagulating. There is also the pus of scrofula, melanosis, and fungus hæmatodes. Persons have been inoculated with scrofulous pus, and with cancerous matter, without any ill result.

But this only proves that healthy tissues are not liable to scrofula or cancer. The experiment should have been tried by applying scrofulous matter to tubercles, and cancerous matter to scirrhus. Pus furnished by the inflammation of natural tissues, will produce a similar disease elsewhere; as is proved by lues venerea, ophthalmia, &c.

It has been supposed that hectic fever resulted from the absorption of pus; but in case even of large abscesses, there is no hectic till they are opened, a new action is set up for the restoration of the diseased parts, and there is often hectic when there is no pus.

(6.) *Gangrene*. This is said to be either dry or moist. Dry gangrene results from the obliteration of the small arteries; moist gangrene is the consequence of inflammation. The symptoms of humid gangrene are at first those of inflammation. The part then becomes of a purple colour; the pain goes off at once; there is a bad odour with crepitation from the effusion of air under the cuticle, in consequence of putrefaction. If the latter takes place, so that the part is easily torn, it amounts to sphacelus, or the death of the part. If the blood be pressed out in gangrene, it does not return. Dry gangrene appears to arise from a defect of nourishment. There is no bad odour, and the part does not putrify, but becomes a dry mass and falls away, like umbilical cord, or like the leaf of a tree in Autumn.

7. *Functional Proximate Cause*.—This may consist either in increased action, diminished action, or perverted action. A spasm is an example of the first, paralysis of the second, and a convulsion of the third. Spasm does not necessarily diminish the calibre of an organ, probably because it affects only a part of the length of the muscles attached; and hence the dragging away of one part from the others, may be partly the cause of the pain which is felt. A tremor is a loss of balance of muscular power from diminished action, and approaches to palsy. A convulsion is a loss of balance from increased action, and approaches to spasm. A clonic spasm is a convulsion; palpitation of the heart is an example of it.

SEMEIOLOGY.

Dr. Gregory says that the symptoms of diseases may be divided into three classes. 1. Impeded functions. 2. Altered appearances. 3. Uneasy sensations. The second may be judged of without asking any questions; the third must be learned from the patient; and the first is to be inferred by comparing the other two. But sensation is a function, and belongs therefore to the first class, although marked as the third; and many symptoms (heat for instance) are referable to all three. The French divide them into three likewise, but differently. 1. Com

memorative symptoms. 2. Diagnostic symptoms. 3. Prognostic symptoms. This arrangement may be very well for individual diseases, but not for a general scheme; for a symptom which is commemorative in one disease, may be diagnostic in another, and prognostic in a third. I divide them into two. 1. Altered appearances, or anatomical symptoms. 2. Altered functions, or physiological symptoms.

1. *Anatomical Symptoms*.—Alterations from disease may take place in the aspect and sensible properties of all parts of the body. Those particularly worthy of notice, in this respect, are the chest, abdomen, nostrils, eyes, general integuments, &c.

1. *Thorax*.—The external aspect of the chest is not much altered in disease. It may be enlarged or contracted, and those states comprise almost all the sensible changes of which they are susceptible. It is enlarged from collections of air, water, or pus, within. It may be contracted, generally on one side, from pleuritic adhesions, and after paracentesis. Adhesions of the pleura cause difficulty of breathing in the lung to which they correspond, so that the muscles are not used on the left side so much as on the other, and this causes a diminution of size, which may be ascertained by admeasurement. This is Laennec's plan. Succussion is as old as Hippocrates. It is used in hydrothorax, hæmorthorax, and pleuritis; but these must be combined with pneumothorax, in order to render it available. Percussion was introduced by Avenbrugger. It is used in all organic diseases of the lungs. The sound on percussion is dull in hydrothorax, pulmonary apoplexy, hepatization, empyema, tubercles, in all dispositions of solids or fluids, and in short in all diseases of the lungs, except pneumothorax and emphysema.

2. *Abdomen*.—The abdomen may be contracted or enlarged. It is contracted in colic for instance, in which disease it has likewise a knotted feel. It is tumid in ascites, physconia, &c.

3. *Nostrils*.—The nostrils are dilated in phrenitis, tetanus, and all diseases of excitement and impeded respiration. They are constricted in asphyxia, and all diseases of depression. This constriction is very remarkable in the hippocratic countenance, which depends on defective muscular action. It is likewise characterized by collapse of the temples, opening of the mouth, and hanging of the lips. The hectic countenance is distinguished

from it by redness of the cheeks. In all particulars it resembles the hippocratic, but depends on a different cause,—the want of fat. This absorption of fat, which causes general emaciation of the body in hectic, was thought by Cullen to be for the purpose of counteracting the acrimony of the absorbed pus; in the same way as in girls who drink vinegar, to make themselves thin, the fat was thought to be absorbed in order to counteract the acrimony of the blood produced by acid. The expansion of the nostrils in dyspnoea is not for the purpose of admitting more air, for if that were the case the mouth would be open; but it is owing to the great stimulus applied to the portio dura, which sets all the muscles supplied by it into energetic action.

LECTURES ON SURGERY.

By JOHN HUNTER, F.R.S.

Of the Heat of Animals.

It has been much disputed whether heat is matter, or only a property of matter. If it is simply matter, then wherever there is heat there must be that matter present. If heat is a property of matter, there must be both matter and property present. If heat is only an action in a particular matter, then there is that matter with its action, as also the body which throws this matter into the action.

Heat and cold are opposite principles, and cannot inhabit the same place. They occupy different parts of the globe, and in some places alternately; these, therefore, are subject to the variations of temperature, which cause varieties of climate. These will be further spoken of hereafter.

Heat, although not equally distributed all over the globe, yet exists in such a degree as to pervade all matter, and is therefore to be found in some proportion everywhere. Heat destroys attractions of all kinds, by which means it becomes the principle of fluidity, and consequently the reverse of the cohesive attraction, or principle of solidity. By means of this effect, motion is allowed to take place among the particles of matter. We have no other idea respecting the variations of heat, except as regards quantity. The quantity of heat has always been estimated by some visible effects, at first probably by our sensations alone, but afterwards by its effects on the expansion of bodies, especially of metals, all of which is called

sensible heat. But it has been discovered lately that many bodies retain more heat than can be made sensible by any of the commonly constructed instruments; therefore a body may have the matter of heat in it without its producing any sensible effects. Hence heat has now been divided by some into sensible and absolute heat. It may be possible that many bodies may have their whole heat made sensible; if so, then their sensible and absolute heat are the same. But it is most probable that the absolute heat of a body can never be known, for the measure of the quantities of heat from every experiment is always by sensible heat, which can never be a proof of the absolute heat in a body.

The real increase of heat must alter the position of parts so as to produce the sensation called heat; and as this heat is diminished, the texture or position of the parts is altered the contrary way, which, when carried to a certain degree, becomes the cause of the sensation of cold. Now these sensations could not take place without a real increase or decrease of heat in the parts. When heat is applied to the skin, it becomes hot in some degree, according to the application. This may be carried so far as actually to burn the living parts. On the contrary, in a cold atmosphere a man's hand shall become so cold as to lose the sensation of cold altogether, and change for that of pain.

Real heat and cold may be carried so far as to alter the texture of parts on which the actions of life depend. Nature has allowed the heat of most animals to come much lower than the heat necessary for performing all their natural functions. This is most so in the more imperfect animals, although it exists in a considerable degree in those possessed of a better regulated standard of heat as the most perfect.

This answers the wisest purposes, for by allowing the heat to come to that degree in which many actions are suspended, or annihilated, the state of the animal is adapted to the state of the atmosphere, which is such as would render the effects of those actions unnecessary, or of no effect.

The first action that is suspended is the propagation of the species; for if birds were to hatch, or animals to bring forth their young, in winter, there would soon be an end to propagation in the temperate and frigid zone, as animals in general only breed once a year.

Cold also annihilates the powers of digestion in all those animals whose food

is rendered impossible to be procured in the winter, and which have not power of emigration, such as frogs, lizards, snakes, bats, hedgehogs, &c.

The power of generating heat was the first considered; the possibility of generating cold being hardly suspected, because most people who made observations on this subject lived in an atmosphere colder than their own body. They observed, that in almost all animals there was a standard of heat, which in common language has been called blood-heat. However, they extended their observations a little further, and called a certain number of animals the cold-blooded animals, but made no experiments either to ascertain the effects or the principle on which they depended.

If we examine any class of animals, we shall find them, more or less, endowed with this principle, though varying from one another very materially in this respect. The heat of the human body being always considerable, even in the coldest climate, it has necessarily attracted a good deal of the attention of philosophers and physiologists, and various have been the opinions which they have formed respecting its cause.

Friction being a cause of the production of heat in many bodies, was supposed to be the cause of heat in animals, especially too, as they thought it could easily be explained on this principle, for they observed there was sufficient motion in the body for such an effect, which motion was principally that of the blood. They calculated the size of the internal surfaces of the arteries, which increases as they divide. They calculated the size and number of the red globules; all of which furnished an amazing extent of surface for friction; and when they calculated the velocity of the blood moving on this extent of surface, as also of the globules on one another, they thought they saw a sufficient cause for the heat of the body, especially as they saw that when this motion was increased, as in fever, the heat was to appearance greater. But we may say at the same time, that they did not see the objections to this theory, which are many.

Dr. Stevenson observed, that there was another cause for the production of heat besides friction, viz. fermentation, and on this principle he accounted for animal heat. But the fermentation of animal substances does not produce heat.

The superstructure built on the foundation that the friction, from the motion of the

blood, is the cause of animal heat, falls immediately to the ground on the observation that fluids have no power of generating heat; nor have two solids, if kept asunder by the intervention of a fluid of any kind. If this had not been a fact, still friction probably would not have accounted for all the variety in the production of heat. Nor could the principle of fermentation account for all the phenomena which attend the heat of animals; therefore some other principle must be referred to as the cause.

It being discovered that the absolute heat of bodies differ very much in different substances, and perhaps in the same substances differently combined, it was thought that this would account for the production and continuation of animal heat. It is supposed that the air which we inspire has much more absolute heat than the same air when we expire it, and that the superabundant heat of the inspired air is given to the animal. But this chemical method of accounting for heat will not account for all the varieties in the heat of animals at different times, especially in disease, when the breathing does not equally vary or correspond with the heat of the animal.

A remarkable case fell under my observation of a gentleman who was taken with an apoplectic fit. He lay insensible in bed, covered with the blankets. I found his whole body would become extremely cold in every part, and continue so some time, and in a short time would become extremely hot. While this was going on, several hours alternately, there was no sensible alteration either in the pulse or the breathing.

A man fell from his horse, and pitched on his head, and produced all the symptoms of a violent injury. There was concussion and perhaps extravasation of blood, but no fracture could be seen. The pulse was at first 120 beats, but came to 100, and sometimes to 90, and was strong, full, and rather hard. He was very hot in the skin, but breathed remarkably slow, only half the common frequency.

His breathing, pulse, and heat therefore did not correspond with this theory of heat.

February, 1781.—A boy about three years old appeared not quite so well as common, being attacked with a kind of shortness of breathing in the night. It had become exceedingly oppressive about 1 o'clock on Sunday morning, so difficult that he appeared dying for want of breath.

In this state he lay till ten o'clock when I saw him. He was breathing so slowly that I thought every breath would be his last, about two and a half inspirations, or even less, in a minute. (The common rate of breathing in such a boy is about thirty inspirations in a minute, and about twenty in a man.) When he drew his breath it was with a jerk; but his expiration was extremely slow, generally continuing through five seconds. I often could not distinguish the pulse, at other times it was very manifest, although very faint and slow, not more than sixty. On tying up the arm the vein did not rise in the least, so that the blood did not go its round. His eyes were turned under the upper eyelid; while his body had a purple cast, especially the lips, which is easily accounted for,—it was owing to the blood not getting the scarlet red in its passage through the lungs, and whatever it might get there was lost in its slow motion through the arteries of the body. He had a fine warmth on the skin all over the body, although in a room without a fire, not covered with more clothes than common in the month of February, with snow falling at noon.

Here it cannot be said that the heat of the body, which was neither great nor deficient, could arise from the constant supply furnished by respiration.

It appears from the account given in the Philosophical Transactions of the experiments made in the heated room, under the direction of Dr. George Fordyce, that Dr. Cullen long ago suggested many arguments to show that life itself had a power of generating heat, independently of any common mechanical or chemical means; though we may observe, that the experiments here related only tend to show the power of producing cold, which they effectually do.

I own I had formed an opinion on this subject. I rather supposed that animal heat was owing to some decomposition going on in the body, and in pretty regular progression, though not the process of fermentations, though not the process of fermentation.

In consequence of an experiment made on two carp, to explain another principle in the animal œconomy, (where every common action was meant to be wholly suppressed, or so far suppressed as to render them incapable of producing heat,) I found an effect produced while the animals were under the experiment which I did not suspect. I began, in consequence, to suspect some other cause of heat than

the common or natural actions of an animal; for during the experiment I observed a remarkable reproduction of heat taking place in these two animals. Until this time I had not an idea that there was a possibility of calling the principle forth, or that cold could excite it.

Experiment.—In the year 1766 two carp were put into a glass vessel with common river water, and the vessel was put into a freezing-mixture. The water surrounding the fish froze very rapidly on the inside of the glass all round. When the freezing-process approached the fish it became as it were stationary; and the remaining water not freezing fast enough, in order to make it freeze sooner I put in as much cold snow as made the whole thick. The snow round the carp melted. I put in more snow, which melted also. This was repeated several times, till I grew tired, and I left them covered up to freeze by the joint operation of the mixture and the atmosphere. After having exhausted the whole power of life in the production of heat, they froze; but that life was gone could not be known till we thawed the animals, which was done very gradually. But with their flexibility they did not recover action, so that they were really dead. Till this time I had imagined that it might be possible to prolong life to any period by freezing a person in the frigid zone, as I thought all action and waste would cease until the body was thawed. I thought that if a man would give up the last ten years of his life to this kind of alternate oblivion and action, it might be prolonged to a thousand years; and by getting himself thawed every hundred years, he might learn what had happened during his frozen condition. Like other schemers, I thought I should make my fortune by it; but this experiment undeceived me.

This experiment laid the basis of many of my future conjectures on animal heat.

I think we may observe in the common occurrences of life that for the actions of an animal a certain quantity of heat is necessary; and this quantity I find to be in some degree according to those actions, the greatest degree of heat being always wanted for the least essential action in every order of animals. However, every order of animals in general requires a heat peculiar to itself, though not always so, some admitting of a much greater variety than others even of the same order, as in the insect tribe.

The actions of an animal may be placed in the following order with respect to its

heat, which is the inverse order to that of their immediate use in the machine. Propagation first; digestion; sensation, in which may be included wakefulness; secretion; circulation; each requiring its degree of heat for complete action. Propagation requires the greatest, digestion may be carried on with a degree less, secretion in two degrees less than propagation, and so on.

In the insect tribe there is a difference between a bee and a wasp and many flies. A bee at all times requires a heat above 20 (?) degrees to support life with ease, while a wasp can allow its heat to vary with the atmosphere without losing life.

A CASE OF FATAL POISONING BY ARSENIUS ACID:

*With Remarks on the Solubility of that
Poison in Water and other Menstrua.*

By MR. ALFRED S. TAYLOR.

(From Guy's Hospital Reports.)

A female, aged twenty-five, was admitted into Guy's Hospital, May 17, 1836, under the care of Mr. Cooper, suffering from symptoms of poisoning by arsenic.

It appears, that about four o'clock in the afternoon of that day, she had taken a quantity of arsenic, which, from her description, must have amounted to about forty grains. She procured it in a small lump, reduced it to a coarse powder, which she then loosely mixed with water, and in that state she swallowed it. In about an hour afterwards she became very ill, and vomited: she had pain the stomach, great thirst, and a sense of constriction in the throat. A medical practitioner, who was called in, administered emetics and mucilaginous drinks, from which she experienced some relief. She became worse in the course of an hour or two, and was subsequently brought to the Hospital. This was about eleven o'clock in the evening, and, therefore, about seven hours after she had taken the poison. She was then labouring under the following symptoms:—the countenance was pale and anxious; the extremities were cold; there was occasional vomiting; great thirst; and the tongue was moist, but very red; the pain in the stomach was not great, and not increased by pressure; the pulse was 134, very irregular, but rather full; there was no pain in the

head; and her mental faculties were unimpaired.

As she had, previously to her admission taken emetics, which had acted freely, it was not thought necessary to resort to any further exhibition of them. A saponaceous mixture, consisting of equal parts of oil and lime-water, was, however, thrown into the stomach, by means of the stomach-pump. This was for the purpose of enveloping any residuary particles of poison, and sheathing the coats of the organ from their influence. The stomach was first well washed out with this mixture, and then about three ounces of it, mixed with forty drops of tincture of opium, were injected into the organ, and allowed to remain there.

She was seen the following morning, at half-past one; she then complained of great thirst, but there was no increase of pain in the stomach. Her tongue was dry and red; her extremities had become warm; there was no pain in the head. The heart was acting rapidly, but feebly; the pulse being about 132, small and feeble. After this, she obtained some rest for about an hour and a half; but she then became extremely restless, repeatedly calling for liquids. The thirst continued unabated untill her death, which took place at a quarter-past seven in the morning, a little more than *fifteen hours* after having taken the poison. Just before her death, her parents came to see her; she was then very restless, but perfectly sensible. She had sat up in bed, and was in the act of drinking, when she suddenly had a slight convulsive fit, and almost instantly died.

The body was examined by Mr. King about eight hours after death. The thoracic viscera presented no appearances calling for notice; but the lining membrane of the bronchiæ was rather dark in colour, and congested.

On opening the abdomen, and exposing the cavity of the stomach, this organ was found to contain a dirty yellow-coloured liquid, somewhat tenacious and holding, diffused through it, opaque grains of a white matter, evidently arsenic. Particles of the same substance, enveloped in mucus, were found scattered over the surface of the mucous membrane in different parts. The appearances presented by the stomach, when seen and examined shortly after its removal, was as follows. The mucous membrane was very rugose, especially at the larger extremity and inferior portion. The edges of the rugæ were, for the most part, vas-

cular; whilst, in the intervening depressions, there were here and there dark-coloured patches of blood, extravasated beneath the mucous membrane. There was great vascularity of the membrane in the upper part of the organ; and there were three distinct lines, of a vermilion redness (the colour having become a little more intense by exposure) running parallel to each other, for nearly the whole of the interspace between the pyloric and the cardiac orifices. These lines terminated in a well-defined margin of redness, situated at the junction of the cardia with the œsophagus.

The most striking morbid changes, however, in the stomach existed near the larger curvature, towards the pyloric extremity. Here there was a large prominent oval patch of thickened membrane, about three inches in length and two inches in breadth. This patch was, in the first instance, covered with a dense layer of opaque mucus, with difficulty separable, containing small granules of arsenic diffused in a white pasty mass. When the surface was washed, it was seen to be of a yellowish colour in the centre, and it was surrounded by a dark margin, as of extravasated blood. At this part, the coats of the stomach were at least three-quarters of an inch in thickness. There was no trace of ulceration or corrosion in any part of the mucous membrane. The peritoneal coat was slightly injected.

In the report of the examination, it is stated that the small intestines contained a great quantity of viscid mucus, tinged with bile. The duodenum was but slightly vascular; but the jejunum was in a high state of inflammation, in circumscribed patches, these portions of the mucous membrane being covered with an easily separable layer of mucus. The lining membrane of the last twelve inches of the ileum, as well as that of the cæcum, was slightly inflamed. The rest of the intestinal canal, with the other organs of the abdomen, presented no abnormal appearances. From the condition of the uterus and its appendages, there was reason to suspect that impregnation had recently taken place.

The head was not examined.

This case appears to me to be worthy of attention in several points of view. The time at which the symptoms commenced, after the poison had been swallowed, was about the ordinary period; namely, *an hour*. The most remarkable circumstance, in their history, is, the general absence of pain throughout the pro-

gress of the case. It is true, that, in the first instance, there was pain in the stomach; but this soon abated, and did not afterwards return to any perceptible extent. In the generality of cases of poisoning by arsenic, pain is one of the most striking symptoms, especially in those in which the post mortem inspection reveals such extensive changes in the stomach as were met with in this instance. In arsenical poisoning, also, the pain is commonly excruciating, being compared by the patient to a fire burning within his body. It is, generally, much aggravated on pressure; and goes on increasing in intensity, with only occasional remissions, until the time of death; but here, these features are entirely wanting. Several instances are on record, in which this symptom of poisoning by arsenic has been absent; and we ought, therefore, in suspected cases, to be prepared for such an anomaly. Dr. Christison mentions an instance of this kind, and others are reported by Orfila. In general, where the pain in the abdomen is slight, death takes place much more speedily, and the post-mortem changes are much less extensive than in the case before us. Dr. Christison has formed a separate group of these cases, constituting his second variety of poisoning by arsenic, in which symptoms of cerebral disturbance are often manifested. Here, however, it is to be observed, the mental faculties remained unimpaired till the last; and neither comatose symptoms nor convulsions manifested themselves during the progress of the case.

One of the most prominent symptoms under which the deceased laboured was the *extreme thirst*, which she in vain endeavoured to assuage by having constant recourse to liquids. I have noticed the presence of this symptom, to a similar extent in three other cases which have fallen under my observation. It certainly is not always present in arsenical poisoning; but, at the same time, I think too little notice has been taken of it by British toxicologists. One of our best writers on toxicology, Dr. Christison, mentions this symptom only in a cursory manner. Continental medical jurists, however, attach full importance to this sign; and Prof. Martini looks upon it, when conjoined with dryness and constriction of the fauces, as affording the most certain evidence of irritant poisoning. The other symptoms require no particular remark.

The treatment pursued was perhaps the best which, under the circumstances,

could have been applied. The viscid mixture of oil and lime-water was well adapted to sheathe the coats of the stomach, and, certainly, by more effectually enveloping and retaining the undissolved portions of the poison, to facilitate its removal by the stomach-pump, from the cavity of the organ. Lime-water has been proposed as a chemical antidote in poisoning by arsenic; but in the case before us, its mechanical operation, mixed with oil, was alone relied on. Lime, it is true, will combine with arsenious acid, and form an arsenite; but this arsenite is easily redissolved, either by a slight excess of the poison, or by the presence of a small quantity of acid, such as that which is ordinarily contained within the stomach. Besides, the arsenite of lime thus formed, like the other arsenites which are insoluble in water, is capable of acting deleteriously, so that the alleged antidotal powers of lime-water are now generally exploded.

Another point of interest, in a case of poisoning by arsenic, is the period at which death takes place. In that before us, the deceased died within the average period, which may be taken at from *six to twenty-four hours* after the ingestion of the poison, when the dose has been large. Many cases do not prove fatal until from twenty-four to forty-eight hours, while, in some instances, the patient is destroyed in less than six hours. Taking the most severe cases of arsenical poisoning, however—of which this was one—the above may be assumed as the average period within which death will ensue. This question of the time at which arsenic proves fatal is, perhaps, not so interesting in a physiological, as in a medico-legal point of view; but is one for which a practitioner must be prepared. In a trial that took place at the Lewes Assizes, Autumn, 1826, which is referred to by Dr. Christison, the fact of the prisoners' guilt, of which the moral evidence left but little doubt, rested almost entirely upon the decision of this question. The deceased, it appears, died within *three hours* after the only meal at which the prisoners could have administered the poison (arsenic to him; and one of the witnesses for the defence is reported to have assigned, among other reasons, why the deceased had not died from poison, that arsenic never destroys life within so short a period as three hours. Dr. Christison very properly censures so dogmatical an opinion, and adduces many cases to show that life may be very rapidly destroyed by this poison. The shortest case, quoted by

him from a German writer, proved fatal in *three hours*. There are numerous instances on record, in which life has been destroyed in from three to six hours after the taking of the poison; and I find an instance, reported by Meckel, in which death followed in *two hours and a half*. A case of probable poisoning by arsenic is mentioned by Remer, which proved fatal within *half an hour* after the ingestion of the poison. Setting aside the last case referred to, we see that arsenic may destroy life within a very short period of time, although it is comparatively rare to find it proving fatal in less than six hours.

In looking over the post-mortem appearances, we find the chief seat of mischief, as usual, in the stomach. The extreme degree to which inflammation of the mucous membrane of this organ had advanced, within the short period of fifteen hours, is, however, worthy of remark. The local irritant action of the poison was here most regularly manifested, but there was neither ulceration nor gangrene. The effusion of dark blood beneath the mucous tunic has, perhaps, often given rise to the supposition of the existence of gangrenous spots in the stomach, in cases of arsenical poisoning. These patches of extravasation existed here chiefly in the interspaces of the rugæ, as well as around the raised oval portion of the stomach, at the pyloric extremity. The coats of the viscus were much thickened in the last mentioned situation; a condition which does not appear to be very unfrequent; and, perhaps, on the whole, is a much more common morbid change from arsenic, than perforation. Metzger met with this thickened state of the coats of the stomach; and Pyl reports a case in which the parietes of the viscus had twice there usual thickness.

Lastly, it remains for me to describe the plan pursued for the identification of the poison. The confession made by the deceased, as well as the nature of the symptoms, left but little doubt that arsenic had been taken; but a case is always rendered more satisfactory when, to these sources of evidence, we can add the certainty commonly derivable from chemical analysis.

Knowing that the poison had been swallowed in the state of a coarse powder, I considered it not unlikely that some undissolved particles might exist in the contents of the stomach. The liquid found in this organ was of a yellowish colour, and of thick gruelly consistency, containing, diffused through it, lumps of coagu-

lated matter. A portion of this liquid was diluted with warm distilled water, placed in a glass vessel tapering to a point at the bottom, and then violently shaken. After waiting a minute the liquid was rapidly poured off into a dish, and at the bottom of the glass numerous hard masses, apparently of arsenious acid, slightly discoloured, were found. These were picked out, dried, and heated with black flux, when several well-defined rings of metallic arsenic were obtained. This process of separating arsenious acid, by its great specific gravity, I have often found to answer, where the viscosity of the liquid containing it, had been removed by the addition of distilled water. In this way, the examiner may frequently save himself a great deal of trouble and research.

Another portion of the contents of the stomach, diluted with distilled water, and well acidulated with acetic acid, was now boiled for two hours. It was filtered while hot through fine muslin, and afterwards through paper; this, owing to the abundance of organic matter, was a very slow process. The liquid obtained by this second filtration was still turbid; but it contained comparatively little organic matter, although sufficient to prevent entirely the application of the silver and copper tests. The filtered liquid was now divided into two portions. Into the first, after it had been acidulated with acetic acid, sulphuretted hydrogen gas was passed to saturation: a golden-yellow coloured compound was speedily formed, which slowly subsided, after boiling the solution to drive off any excess of the gas. The precipitate thus obtained was obtained was proved to be sesquisulphuret of arsenic:—1st, by its insolubility in the mineral acids; 2dly, by its perfect solubility in strong liquor ammoniæ; and 3dly, by its yielding a ring of metallic arsenic, when slowly heated with four times its weight of black flux. The precipitated sesquisulphuret was combined with a portion of extraneous matter; but I have never found this an obstacle to the determination of its true chimeical characters, except when the foreign matter has been in unusually large quantity. The sesquisulphuret is not so easily reduced to the metallic state as arsenious acid; it requires a larger quantity of flux, and it is, perhaps, better to use a lower heat, and to apply it more slowly, than in the case of arsenious acid.

The second portion of filtered liquid, having been slightly reduced its bulk by

evaporation, was now treated with an excess of alcohol, and introduced into the ingenious apparatus which had been then but recently proposed by Mr. Marsh, of Woolwich, for the detection of minute quantities of arsenic. The principle of this discovery is, to generate hydrogen gas slowly in the midst of a liquid containing any arsenious or arsenic acid, or any of the soluble salts formed by the union of these acids with bases. In all of these instances, the nascent hydrogen combines with the *metallic arsenic*, resulting from the decomposition of the acid or salt, and forms a gas well known as the arseniuretted hydrogen. This gas is generated under the pressure of a column of water, in a glass tube bent upon itself, so that the two legs (one of which is only half the length of the other) are parallel. The shorter leg is provided with a stop-cock; and it is in this leg that the gas is produced, by dropping a piece of metallic zinc into the suspected poisonous liquid previously acidulated with sulphuric acid. When the arseniuretted hydrogen has collected so as to fill the shorter leg of the tube, it is allowed to escape from the stop-cock; and at this moment, if a lighted taper be applied, it will burn with a dull white flame; and if, at the same instant, a plate of clean glass be brought over the flame, a circular stain of metallic arsenic is formed upon it, whilst the combustion of hydrogen, at the same time, produces a ring of aqueous vapour around the metallic stain. In some instances, the quantity of arsenic deposited in the metallic state is such, that a perfect leaf of the metal may be raised from the surface of the glass.

In the case before us, upwards of twenty crusts of metallic arsenic were produced from about three drachms of the filtered liquid, treated with alcohol. The object of using alcohol, is to prevent the frothing of the liquid within the tube, which, in a mixture containing organic matter, is very likely to occur; and when this does occur, it interferes with the free escape and combustion of the gas. The precise nature of the sublimate was determined by the corroborative experiment mentioned in the note.

The contents of a portion of the jejunum, which had been insulated for the purpose of examination, were now submitted to analysis by the same processes, and with equally satisfactory results. The hydrogen test showed that arsenic was abundantly present in the fluids of this part of the alimentary canal.

THE ANATOMIST.

Spinal nerves.—Symmetrical, 30 pairs, viz.:—8 cervical, 12 dorsal, 5 lumbar, and 5 sacral. Each spinal nerve has two roots, an anterior and a posterior. The anterior is small, and is the motor division. The posterior large, with a ganglion upon it, and is for sensation. These roots are separated by the chord itself, and by the ligamenta denticulata. The anterior root is connected to the surface of the ganglion of the posterior root. On the outer side of the ganglion both nerves unite in a single chord, which, after a short course, divides into an anterior and posterior branch. The posterior branches are the smaller, (except that of the second cervical) and are distributed to the dorsal muscles and integuments. The anterior branches form the several plexuses, and supply the muscles and integuments anterior to the spine, and also the extremities.

Distribution of the eight Cervical Nerves and First Dorsal Nerve.—*Posterior branches* are small, except the second cervical, which accompanies the occipital artery; the rest are lost in the neighbouring muscles and integuments. *Anterior branches*.—The first, or sub-occipital, twists round the atlas, to unite with the second, forming the nervous loop of the atlas: and the second, having received the first, descends to unite with the third. The third unites in like manner with the fourth, and thus is formed, by the anterior branches of the four first cervical nerves, the *Cervical Plexus*. From this plexus proceed. 1. *Ascending superficial branches* to the platysma, integuments, parotid gland, ear, and back of the head. One of these is called *ascendens colli*, which arising chiefly from the third cervical, is distributed to the ear; it accompanies the external jugular vein. 2. *Ascending deep branches* which supply sterno-cleido-mastoid, digastric, splenius, and adjacent muscles. 3. *Descending internal branches*, which send a superficial branch to join the descendens noni and the deep or *phrenic*, or *internal respiratory*. This nerve comes chiefly from the fourth cervical, and often receives a filament from the brachial plexus, having sent small filaments to the liver, œsophagus, inferior cava, and stomach; it ultimately distributes itself to the diaphragm. 4. *Descending external branches*. The superficial branches of this set are distributed to the clavicle, acromion, pectoral,

and deltoid muscles and integuments; and the deep branches to muscles of the neck and scapula, one of which (the largest) is given to the serratus magnus muscle, and is the *external respiratory nerve*.

The Brachial Plexus is formed by the union of the anterior branches of the four inferior cervical and first dorsal nerves. From this plexus proceed *Thoracic nerves*, they are four or five in number, and come off from the upper part of the upper part of the plexus; they divide into—1. anterior thoracic branches, which descend behind the clavicle, in front of the axillary artery, and supply the pectoral muscles. 2. Posterior thoracic branches, which pass behind the axillary vessels to the serratus magnus and rhomboid muscles. *Supra-scapular nerve* passes through the notch in the scapula, and supplies the supra-spinatus, infra-spinatus, and teres muscles. *Subscapular nerves* are three or four in number, and descend behind the vessels to the subscapular, latissimus dorsi, and teres major muscles. *Internal cutaneous nerve*. 1. External branch, which descends over the bend of the elbow, as low as the wrist. Internal branch descends towards inner condyle, and sends branches to inner and posterior part of the fore-arm. *External cutaneous*, musculo cutaneous or perforans lasserii. 1. Branches to coraco-brachialis biceps and brachii anticus. 2. Anterior branch to the ball of the thumb and palm of the hand. 3. Posterior branch to the dorsum of the hand. *Median nerve*, or brachial nerve. 1. Branches to superficial and deep pronators and flexors. 2. Anterior interosseal nerve, which supplies the deep flexors, and binds a branch to the pronator quadratus, and another to the dorsum of the hand. 3. Superficial branch given off above the wrist, which runs to the palm of the hand. 4. Five digital branches, which supply the thumb, index, and fore fingers, and the radial edge of the ring finger. *Ulnar nerve*. 1. Muscular branches to triceps, flexor sublimis, and flexor ulnaris muscles. 2. Dorsalis carpi ulnaris to integuments on the dorsum of the hand and the three inner fingers. 3. Superficial palmar branch divides into three digital branches, which supply the little finger and the ulnar edge of the ring finger. 4. Deep palmar branch form the deep palmar arch, and supplies the interossei muscles. *Musculo spiral*, or radial nerve. 1. Branches to the triceps. 2. Large or long cutaneous branch to the thumb.

3. Branches to the supinators and extensors. 4. Anterior or radial branch runs along the inner side of the supinator radii longus, which it supplies, and sends a branch to the integuments of the thumb, and another to the dorsum of the hand, supplying the index and middle fingers, and communicating with the dorsalis ulnaris. 5. Deep branch, or posterior interosseal, supplies by superficial and deep branches the extensor muscles. 1. *Circumflex, or articular nerve*. 1. Branches to the subscapular and adjacent muscles. 2. Principal distribution to the deltoid muscle.

Twelve pair of Dorsal Nerves.—*Posterior branches* are small, and pass backwards to the muscles and integuments of the back and loins. *Anterior branches, or Intercostals*. 1st is the largest; it contributes to the formation of the brachial plexus. 2nd 3d run backwards and outwards, and at the angle of the ribs pass between the intercostal muscles, and running along the lower edge of each rib, rapidly the surrounding muscles: opposite the axilla they send off the *nerves of Wrisberg*, or cutaneous nerves of the arm, and terminal branches to supply the muscles and skin upon the lateral and forepart of the thorax. 4th to 12th inclusive are similar to the 2d and 3d in distribution, supplying the intercostal and adjacent muscles: the two last go chiefly to the diaphragm, and the 12th sends a branch to join the first lumbar. [All the intercostals are connected by two short branches to the ganglions of the sympathetic.]

Five pair of Lumbar Nerves.—They are larger than the dorsal, and like them divide into posterior and anterior branches. *Posterior branches* are distributed to the lumbar muscles. *Anterior branches* unite in the substance of the psoas muscle, to form the lumbar plexus.

Lumbar Plexus.—*External inguino-cutaneous*. 1. Branches to the abdominal muscles. 2. Cutaneous branch to the integuments on the outer part of the thigh. 3. External spermatic nerve. *Middle inguino-cutaneous* to the skin, on the outer part of the thigh. *Internal inguino-cutaneous*. 1. Branch to the spermatic chord, accompanying the spermatic vessels. 2. Branch to the integuments and glands of the groin. *Anterior crural nerve* formed by the four superior nerves, passes beneath Poupart's ligament, and divides into two fasciculi. 1. *Superficial fasciculus*—four or five long branches, which pierce the fascia lata, and

descend to the knee, some of them accompany the saphena vein. 2. *Deep fasciculus* sends *external muscular branches* to vastus internus, rectus, iliacus internus, and tensor vaginæ femoris, and internal muscular branches to the sartorius, vastus internus, and cruræus: branches accompanying the femoral artery, near to the knee, and the *internal saphæus nerve*, which joins the saphena vein at the knee, lying between the tendons of the gracilis and sartorius; this branch goes on to the inner side of the foot, sending off numerous branches to the integuments. *Obturator nerve* from the third lumbar. 1. Branches to the obturator internus. 2. Anterior branch to the adductor brevis, pectinæus, and vastus internus muscles. 3. Posterior branch to the gracilis adductor magnus and longus muscles. *Lumbo-sacral nerve* from the fourth and fifth lumbar. 1. *Superior glutæal* to glutæus medius and minimus muscles. 2. *Communicating branch* to join the first sacral nerve. Five pair of sacral nerves. *Posterior branches* very small, to muscles and integuments. *Anterior branches* very large, particularly the three superior: these five, with the communicating branch of the lumbo-sacral, form the sacral plexus.

Sacral Plexus sends off internal or pelvic branches, which are named *Hæmorrhoidal, Vesical, Uterine, Vaginal*. External branches. *Lesser sciatic nerve*. 1. Superficial branches pass over the hamstring muscles, with the posterior cutaneous nerve, and are lost in these muscles. 2. Deep branches go to the quadratus femoris, upper part of the adductor magnus, &c., also to the hip joint. *Inferior glutæal nerve*, to the glutæus maximus, perinæum, and the inner side of the thigh. *Posterior cutaneous nerve* to the back part of the thigh and leg. *Pudic nerve*. 1. Inferior branch to the muscles of the perinæum and to the scrotum. 2. Superior branch passes along the dorsum of the penis to the glans. *Great sciatic nerve*, or posterior crural. 1. *Cutaneous and muscular branches*, the latter to the hamstring, gracilis and adductor magnus muscles. 2. *External popliteal, or peroneal nerve*, which sends off the *external cutaneous nerves* of the leg, two or three in number; these communicate with the external saphæus nerve. The *musculo-cutaneous nerve*, which sends branches to the integuments of the first and second toes, called *internal tarsal*, and branches to the integuments on the three outer called *external tarsal*. *Ante-*

rrior tibial nerve, which sends branches to the integuments, a branch to the extensor digitorum brevis, cutaneous and communicating branches, and the terminating branches to the first inter-osseal muscle, and then communicates with the plantar nerve. 3. *Internal popliteal, or posterior tibial nerve*. *Posterior or external saphæus*. Muscular branches to the gastrocnemius, solæus, plantaris, and deep muscles. Small filaments to the posterior and anterior tibial arteries. *Internal plantar nerve* which sends branches to the plantar muscles and skin, and the four digital branches to supply the 1st, 2d, 3d toes, and inner side of the 4th toe. *External plantar nerve*, which sends a superficial branch to the little toe and outer side of the 4th toe, and a deep branch to the plantar and interossei muscles.

SYMPATHETIC OR GANGLIONIC SYSTEM OF NERVES.

The sympathetic nerves communicate by their superior extremities with several of the cerebral nerves by fine filaments, also with all the spinal nerves; by one filament with each cervical, and by two filaments with each dorsal, lumbar, and sacral.

The Cervical Ganglions are three in number. *Superior cervical ganglion* extends from the first to the third cervical vertebra. 1. Ascending or superior branches are two; they ascend along with the carotid artery in the carotid canal to the cavernous sinus, where they communicate with the sixth or abducens nerve, and with the vidian nerve. 2. Descending or inferior branches are filaments which join the laryngeal and vagus nerves, the superior cardiac nerve, and the middle cervical ganglion, if it exists; if not, they join the inferior ganglion. 3. Internal branches unite with pharyngeal plexus. 3. External branches join the superior cervical nerves. 5. Anterior branches from the vagus and facial nerves, and form a plexus around the carotid artery, from which branches proceed along the external carotid and its divisions, and are named accordingly. *Middle cervical ganglion* is sometimes absent. 1. Branches to unite with the vagus and cervical nerves. 2. Branches to join the cardiac nerves. *Inferior cervical ganglion* is situated between the transverse process of the last cervical vertebra and the neck of the first rib. 1. Branches to phrenic nerve, brachial plexus, subclavian

artery, and its branches. 2. Branches to the inferior cardiac nerve.

Cardiac Nerves are three in number, and are named, superior, middle, and inferior. 1. *Superior Cardiac Nerves* arise by two or three filaments from the superior cervical ganglion, communicate with the vagus and laryngeal nerves, and with the middle and inferior cervical ganglia, pass along the coats of the *arteria innominata* on the right side, and between the left carotid and left subclavian on the left side to the aorta, and here communicate with the recurrent nerves, the middle and inferior cardiac nerves, and the cardiac ganglion or plexus. 2. *Middle Cardiac Nerves*. That of the right side is generally the largest; on the left side it is something wanting. They enter the thorax anterior to the subclavian artery, are joined by branches from the vagus and recurrent nerves, and, passing along the *arteria innominata*, terminate in the cardiac ganglion and plexus. 3. *Inferior Cardiac Branches*. The right descend along the *arteria innominata* to the forepart of the arch of the aorta, and terminate in the anterior cardiac plexus: some branches pass between the aorta and pulmonary artery to the cardiac ganglion; on the left these nerves accompany the subclavian artery, and partly join the middle cardiac nerve, and partly the cardiac plexus.

Cardiac Plexus or Cardiac Ganglion, is situated behind the ascending aorta, near its origin, in front of the trachea and right pulmonary artery; it consists of a plexus of nerves formed by the cardiac nerves of the opposite sides and branches of the eighth pair and recurrent. In the meshes of this plexus several small ganglia are enclosed, and to these conjointly the term cardiac ganglion is applied. Branches proceed from this plexus to the coronary and pulmonary vessels to the aorta and vena cava, and to the substance of the heart itself.

Thoracic Ganglions are twelve on each side, sometimes only eleven, the last cervical and first dorsal being united. 1. Branches to the mediastinum, which ramify on the aorta and adjacent vessels, and communicate with the pulmonary plexus. 2. Great Splanchnic nerve is formed by distinct roots, from the 6th, 7th, 8th, 9th, and 10th ganglions, which unite on the 10th dorsal vertebra into one chord, which chord, entering the abdomen along with the aorta, or separated from it by a fasciculus of the diaphragm, expands into the semilunar ganglion. 3. Lesser

Splanchnic Nerve arises by two roots from the 10th and 11th ganglions, and uniting on the side of the last dorsal vertebra, enters the abdomen through the crus of the diaphragm, and ends in the renal plexus.

Semilunar Ganglia are situated on the diaphragm, partly on the aorta, and on either side of the celiac axis, and above and behind the supra-renal capsule. They are the largest ganglia of the sympathetic; several nervous filaments, on which small ganglia are placed, pass from one to the other surrounding the celiac axis, forming a plexus, called

Solar Plexus is situated behind the stomach, above the pancreas, and in front of the aorta. 1. Branches in various directions, accompanying the blood-vessels, forming plexuses around each, and named accordingly, as hepatic, splenic, and gastric, and these communicate with the eighth pair. 2. Branches descending in front of the aorta, which subdivide at the renal and mesenteric arteries, accompanying them, and forming plexuses, named accordingly, viz.; renal, superior and inferior mesenteric, and into each of these branches of the lumbar ganglions enter.

Renal Plexus receives the lesser splanchnic nerves; from it descends 1. Spermatic Plexus, which goes to the testicle in the male and to the ovarium and uterus in the female.

Inferior Mesenteric Plexus sends branches which descend to the brim of the pelvis, unite with others from the lumbar ganglions, and form a plexus around the internal iliac artery and its branches, named hypogastric plexus. It is joined by numerous filaments from the lumbar and sacral ganglions of the sympathetic, and communicates with the pelvic branches of the sacral plexus.

Lumbar Ganglions are five on each side, sometimes only three or four. 1. Branches to anterior branches of lumbar spinal nerves. 2. Branches to assist in forming the several abdominal plexuses.

Sacral Ganglions are three or four in number. 1. Branches to sacral nerves. 2. Filaments to hypogastric and pelvic plexuses. 3. A small branch from the last ganglion, which passes in front of the coccyx, there forming with its fellow the

Ganglion Impar, which sends branches to the coccygeus, levator, and sphincter ani muscles. The Gasserian, Meckel's, Lenticular, Naso-palatine, and Submaxillary Ganglions are described in connection with the fifth pair of Cerebral Nerves, and its ramifications.

The London Medical

AND

Surgical Journal.

Saturday, June 24th, 1837.

THE METROPOLITAN UNIVERSITY.

When the Chancellor of the Exchequer was employed in framing the New University, he exhibited no small degree of acumen, by offering a place in the Senate to certain of the most celebrated corruptionists, who, as public functionaries, he well knew, durst not accept of an office in the new institution; whilst he, at the same time, elected some of their zealous representatives, taking special care that the number of these should be so insignificant, that they should be quite incapable of frustrating the great objects of the University, or of passing by-laws that would in any way prevent the disturbance of the old ladies of the antiquated nunnery in Pall Mall East, or of the ancient monks of Lincoln's Inn Fields. Already have these imbecile representatives of the monopolists been signally defeated on two important points,—not only has Dr. Peter Mark Roget, with his three *enlightened* companions, the Doctor of Laws and the two naval tacticians, been defeated in their contemptible project of establishing SECRET COMMITTEES, the purport of which was too obvious, and what was anticipated by the Chancellor of the Exchequer from such individuals. But this QUADRUPLE ALLIANCE has also met with a severe defeat in not being able to appoint, after all their endeavours, that individual to fill the office of REGISTRAR, who from his well known adhesion to the "great cause," would have been a most useful coadjutor. Finding there was no chance of an annual sum of 1,000*l.* being

extracted from the Treasury chest as stipend for a REGISTRAR, Dr. Forbes of Chichester had the sagacity to withdraw his name from amongst the Candidates; and we cannot help expressing the opinion, already advanced, that the Doctor's great and scientific talents would be better employed in editing his valuable Quarterly, and his acoustic tact devoted to stethoscopic investigations.

Neither has Mr. Warburton been able to carry *his* projected appointment into effect, so that our anatomical teachers will not be deprived of the admirable working of the Anatomy Bill, and the rigid justice in the distribution of subjects so characteristic of the present INSPECTOR OF ANATOMY. Whilst, therefore, there is just cause to rejoice in the defeat of personal objects and intrigues, which have hitherto been attempted in the Metropolitan University, we feel pleasure in stating, that a CLERK has been appointed, with an income of 200*l.* a year, to perform the manifold duties which were supposed to be required of a Registrar, the most important of which it is intended should devolve on the Senate themselves. How the Members of the Senate are to be remunerated for these arduous and no less laborious duties, we know not; but of this we are certain, that propriety and justice demand that they should receive salaries proportionate to the duties which may be imposed upon them.

DEATH OF THE KING.

(From our Windsor Correspondent.)

The forewarnings I communicated to you with respect to the ordinary bulletins have been too truly realized, in the demise of his late Majesty. The state of anxiety which prevailed amongst all classes at Windsor during yesterday,

(Monday) showed the little dependence placed on the official bulletins, from which, as usual, no information whatever could be derived. It is but justice, however to the medical attendants to state, that this last ten days sojourn in this world can only be attributed to the judicious manner in which stimulants of the various kinds were administered. It has been generally reported by one party here, that the last few days of his Majesty's life were embittered by sufferings of no ordinary description; but the very contrary, you may depend upon, was the fact. Indeed, when the state of his Majesty's circulation is considered with the collateral circumstances, it would furnish a singular anomaly in the annals of medicine.

The moment arrangements are made for the embalmment to take place, with all other particulars, I shall apprise you.

I regret to state, that from the great anxiety which his royal consort has suffered, she requires the constant attendance of her medical advisers.

MEDICAL CHARITIES BILL FOR IRELAND.

Since it was announced early last winter that it was Lord Morpeth's intention to introduce a bill for the better regulation of the Medical Charities of Ireland, we have been exceedingly anxious to learn what such a bill should be, and how far in principle, and in practice, it may be likely to answer the expectations of the profession and of the public. In the two last numbers of this Journal, we gave the expected bill; and will now state our opinions respecting it, and enter at some length into the subject of medical relief for the sick poor of that country.

In doing so, we enter on the entire
No. 12.

question differently from any of our fellow journalists—we have practised much and long in Ireland, and happen to be well conversant with the different classes of medical charities in that country—we therefore are enabled to discuss the subject *practically*. And as we happen to be now so circumstanced as to have no direct or indirect interest in it, beyond that which we feel as members of a profession which is likely to be greatly affected by such an enactment, and as members of society anxiously alive to the passing of any measures which are intended for the relief of the sick poor of that fine but still much distressed country, our observations will, it is to be hoped, be received without any of that distrust which local or other interests might possibly create in the minds of many.

To enable our readers to fully understand this interesting subject, it is necessary that we should briefly state what means exist in Ireland at present to afford gratuitous medical aid to its numerous sick poor.

The grand jury of each county, city, or town, is authorized to make an annual presentment to the Infirmary of such county, and to give £100. a year to the surgeon. It is not compulsory on them to do so, but in general from £400 to £600 is granted. This, aided by subscriptions, supplies infirmary aid to about 10,000 interns annually in all the counties in Ireland, the City of Dublin alone excepted. The externs attended by these county hospitals are supposed to amount to 170 or 180,000. The annual expenditure is about £27,000 for the thirty-six institutions of this class. The grand juries are authorized to present a sum double the amount of subscriptions for fever hospitals, of which there are in all seventy. The sum total expended on them is about 728,000 a year, and the

number admitted, including the Dublin fever hospitals, about 23,000, of which number above 7,000 enter the latter. It is not legal to apply any funds obtained for fever hospitals for the support of any but cases of supposed contagion.

Grand juries are authorized and *required* to present for Dispensaries a sum equal to the subscriptions. The number of these Institutions is about 482; the sum annually expended on them is about £60,000 a year. The number of patients annually attended by them is above one million.

The funds for District Lunatic Asylums are compulsory, and are advanced by government and repaid by the counties; they amount to about £30,000 a year; the number of patients annually admitted is not stated.

By this it will be observed that there is one Infirmary in each county, supported chiefly by county rates and partly by subscriptions; that Lunatic Asylums are maintained entirely at the expense of a similar rate. Both these classes of charities are therefore provided with certain funds; but those for Fever Hospitals and Dispensaries are entirely dependent on subscriptions; and when the latter fail, there can be no funds for either.

The defects of such legislation are but too apparent, and they are extensively felt. First, as regards county Infirmaries, the whole county is taxed for one institution, whose advantages are found to extend only a few miles around it;* and those requiring infirmary aid are, on that account, as well as from other causes, viz., insufficiency of funds, and want of sufficient room in these infirmaries, unable to obtain it.

This evil might be greatly remedied were the Governors of any Fever Hospital, which is above ten miles distant from the County Infirmary, empowered to use such hospital *partly* for infirmary purposes.

The defective state of the laws regarding Fever Hospitals and Dispensaries is lamentable to contemplate in such a country as Ireland, where want and disease are so general and so frequent. Its consequences are stated by the Irish Poor Inquiry Commissioners (second report, page 4), to be, that "Medical relief at present afforded throughout Ireland is very unequally distributed," "in districts where there are many rich resident proprietors a medical charity (Fever Hospital or Dispensary) is perhaps least wanted, but a subscription most easily obtained; in districts where there are few or no resident proprietors the aid is most necessary, but there are no subscribers, and consequently *there is no medical charity.*"

In proof of this opinion the Commissioners observe, "In the county of Dublin there are twenty-four Dispensaries for 176,000 inhabitants, or one for every 7,333. In Meath, nineteen Dispensaries for 176,800, or one for every 9,306 inhabitants," but "in the county of Mayo, containing 366,328 inhabitants, *there is only one Dispensary supported at the public expense.*"

We beg leave to give a short table to further prove this opinion,—the town of Galway has one Dispensary for a population of 40,000, and *only one medical attendant*; the county of Monaghan has one for every 26,500 of the population; Down one for 29,000; Longford one for 28,000; Kerry one for 23,000; Fermanagh one for 21,400; Antrim one for 21,100; Roscommon one for 20,000; Galway one for 200,000; Armagh one for 18,300; Sligo one for 19,000; Tyrone

* See Phelan's Enquiry into the defects and abuses of the medical charities of Ireland, second and sixth statistical tables.

one for 18,000; Londonderry one for 17,000.

This shows that the medical charities are very unequally distributed; but it shows much more, that many of those which now exist, must be very inadequate to afford the sick poor of their respective districts the necessary relief. It is a fact universally admitted, that one medical man cannot possibly attend a greater number of sick poor, than a population of from 10,000 to 12,000 usually produces. Now there is, *generally*, but one prescriber for each rural Dispensary in Ireland—where there is an apothecary he rarely visits, but merely compounds and gives out medicines, and as the population of the above twelve counties amounts to 2,975,000, it would require from 250 to 300 Dispensary attendants to attend the sick poor sufficiently—in place of 136 which is about the number, now engaged—each district on an average now containing above 21,000 persons, and many of them of such extent as to render it physically impossible for one person to attend perhaps one-half of the sick poor.

Let us now examine twelve other counties, viz., Carlow, Dublin, Kildare, Kilkenny, King's & Queen's counties, Louth, Meath, Westmeath, Wexford, Wicklow and Limerick, which contain a population of 1,794,000, and in which there are 160 Dispensaries, or one to every 11,200 persons. If the number of medical officers attending these be only sufficient, surely in the case of the other counties the defect must be very great. The fact, we believe to be in a few instances, Dispensaries are too near each other; but in other parts of the same counties, and in most instances, they are by far too remote.

Now with regard to Fever Hospital aid—a matter on which the legislature has always laid great stress, and very justly—in a country where fever so much and so

often prevails. In Leinster and Munster there are sixty Fever Hospitals, viz. twenty-nine in the former, and thirty-one in the latter; whilst Ulster and Connaught contain only ten, seven in the former and three in the latter. Four counties, Cork, Tipperary, Wexford, and Wicklow, with a population of only 1,516,000, have twenty-eight, or one to every 54,000 persons; whilst the remainder of Ireland has only forty-two, or one to every 154,000. *Eleven counties contain only one each, and some of these but very small, and seven have yet no Fever Hospital.*

These facts, which we have collected from Surgeon Phelan's valuable work—"An Inquiry into the Defects and Abuses of the Medical Charities of Ireland," and from Appendix B. of the Irish Poor Commissioners Inquiry, being the evidence and report of the four medical gentlemen employed to inspect these institutions, are decisive evidence of the Medical Charities of Ireland being quite insufficient to supply the sick poor with medical aid.

We are aware that since the publication of the above works, the first in 1835, the latter in 1836, a few, and but very few, fever hospitals have been established; but, on the other hand, it is well known that the funds for many of this class, as well as for several dispensaries, have diminished considerably.

The Irish Poor Enquiry Commissioners might then well observe that "The Medical relief at present afforded throughout Ireland is very unequally distributed, and requires considerable alteration;" a subject which we shall consider fully in an early number.

HUMAN LIFE AND THE TABLES OF MORTALITY.

It would only be repeating an acknowledged truth, to say that human life is uncertain, and that its duration varies, according to the age and circumstances of the life proposed. But although age may in some measure denote the value of life, it does not necessarily follow that an equality in age will produce an equality in the duration of existence. There are very few of our readers who could not select, from the circle of their own acquaintance, many who, with equal ages, have by no means an equal prospect of seeing the commencement of another year. During the Patriarchal ages, before the follies and intemperance of mankind had spread disease and its consequent miseries, age might perhaps with propriety have been adopted as the standard measure of longevity; but of later years it has only served to measure out the portion of existence due to mankind collectively. The life of man may terminate at any period between birth and the extremity of old age, and although it would be extremely difficult to assign the exact period at which the dissolution of a single individual might be expected to occur, yet it is by no means so difficult a task to portion out the number of years due to a large mass or body of mankind. The progress of population and the waste of life, have long since been found to be regulated by an absolute and almost unerring law. It is not indeed pretended that the action of this law is everywhere the same. It would be the extreme of folly, to suppose that the duration of existence is the same amongst all nations, and in all climates, at all periods, and among all classes of society; a thousand causes interfere either to increase or diminish the mortality of particular places, and particular periods. Some countries are scourged by periodical endemics, and some periods are marked by scarcity and famine. The waste of life is greater among people who arrive early at maturity, than it is among those in whom maturity is backward. It is for this reason that the natives and inhabitants of warm climates, who are, as it were, forced into premature perfection, seldom or ever reach the extremity of life; nor do we want evidence to show that the waste of life is sensibly affected by the comparative scarcity or abundance of provision. Every material rise in the price of food,

is invariably attended by a corresponding decrease in the number of the yearly births, by an increase in the sickness, and by an excess in the mortality of that year; but, with all this apparent fickleness of nature to contend with, our statisticians have traced the mortality of the different countries and classes of mankind, with an exactness and regularity which is scarcely credible.

The constitution and arrangement of the human frame, however perfect it may originally have been, intimate that it was not formed to continue in healthy action, or to perform with regularity its various functions, for a longer period than seventy or eighty years. From constitutional defects or hereditary weakness,—from intemperance, self-indulgence or folly,—a certain number of every generation fall sick, and of these a certain number annually die, at every age, but in such a manner and by such a law, that the rate of mortality gradually diminishes from birth to puberty, and is from that period gradually accelerated until the extremity of life. Life may, indeed, be said to be divided into three distinct periods or eras, namely:—The period from infancy to puberty, or the commencement of manhood; from and during manhood to the commencement of old age; and from the beginning of that era to the termination of existence. During infancy life is exceedingly precarious, and the mortality of that season far exceeds the mortality of a middle age. This is in a great measure owing to the delicacy of the human frame at this very tender age, and to the fatality of the numerous disorders which infect childhood in its very early states. The period of manhood is marked by a certain but a slow decay, while from old age to death, the velocity of mortality is extremely great. In these papers it will be our object to confine our inquiries to the observations which have been made on the duration of life in our own country, and among our own people, and to the use which has been made of the materials collected in the construction of the various tables of mortality by which the life offices regulate their charges.

The observations, upon the accuracy of which the law of mortality in this kingdom depends, have been chiefly drawn from the examination of the parish registers of different cities, towns, and villages, and from the population and other returns made to Parliament. Other and very different sources have been examined, and have been found to produce data, in some

cases, superior to that procured from the registers of even the oldest parishes. We shall, in the course of this paper, allude to the various sources which have provided data for these enquiries, but we cannot promise more than a very brief sketch of the subject, and a short but succinct account of the three or four principal tables which have been constructed upon the materials furnished by the British empire.

The first important, and the oldest, of these tables, was formed by the celebrated Dr. Price, from the parish registers of the town of Northampton, a small central and healthy borough town, which in itself combines many of the advantages of both town and country. We shall not be able in this place to give a detailed account of the method pursued by Dr. Price in forming this table, the tabular numbers of which are, of course, wholly artificial, and have been produced by a series of mathematical assumptions, but the ground-work of it is substantially correct, and founded upon real observations. It is not to speak too favourably of this table, to say, that frequent use and subsequent experience have concurred in rendering testimony to its value and accuracy, especially in the latter stages of existence. In its tabular form it consists of 11,650 individuals, who are traced from birth to the termination of existence, which, according to this table, is at the age of ninety-six years. The numbers dying in each year are noted, and, consequently, the number surviving to commence the ensuing year. In its form it is as follows:—

Age.	No. Born and Living at the Commencement of each Year.	No. Dying each Yr.
At Birth	11650	3000
At 1 year	8650	1367
„ 2 years	7283	502
„ 3 „	6781	335
„ 4 „	6446	197
„ 5 „	6249	184

From an examination of the above specimen, the nature of these tables will be made apparent; it commences with the birth of 11,650 children, out of which number 3000 are supposed to die the first year, so that the total number of survivors who complete their first, and who enter upon the second year of their age, are equal to 8650; out of this number 1367 die during the second year, leaving 7283 to complete the age of two years, and so on. The numbers in the first column all along represent the survivors who enter upon every new year; and the numbers in

the second column, those who annually die, when the table is carried on to the extremity of life. The total number of deaths (the sum of the second column,) is always equal to the number originally born; and the sum of the first column, or those living at every age, may be said to represent the population of the table, so that had the numbers in the table been real instead of artificial products, that is, had they been equal to the numbers actually living and dying in the town of Northampton, the population in the table would have represented the real contemporaneous population within the walls at the commencement of every year. It will, however, be seen from this, that such an hypothesis is founded on supposition that the population of the town has remained quite stationary for a long series of years, as there is no allowance made for the admission of new settlers or for an efflux by emigration. But the construction and uses of this table will be better explained and more fully understood, when we come to determine from it the probabilities of existence. Although this table has been, until very recently, the one adopted by Government as the basis of its annuity system, and by almost all the principal assurance societies, yet an opinion has lately got abroad, that it gives the mortality of the ages too high, and is consequently too unfavourable to the duration of human life. This opinion, which is almost universally entertained, owes its origin to the fancied improvement which has taken place in the condition of the national health, an improvement supposed to have been produced by the co-operation of several causes, among the most prominent of which we may venture to place the very general introduction of vaccination, and the consequent extirpation of that dreadful malady, the small-pox. How far this opinion is supported by experience, it will presently be our business to examine.

The table next in estimation to the Northampton, is one formed by the ingenious Mr. Milne, upon a series of observations made by Dr. Heyham, on the mortality of the city of Carlisle. It is in its nature, properties, and general arrangement, similar to the Northampton, but in its arithmetical results it differs widely from its rival table. It gives a rate or velocity of mortality considerably less than the Northampton, and consequently supposes life of greater value. It terminates existence at the advanced age of one hundred and four years. The propriety of

adopting so extreme an age may very well be doubted; for although some extraordinary instances have occurred of individuals reaching ages even beyond this, yet they have been so few in number, and are of such rare occurrence, and so unsupported by credible testimony, that it is scarcely prudent to protract a table which is intended for general use, to ages beyond one hundred years.

A very extensive series of tables have been constructed by Mr. Finlaison, the state actuary, from his own observations on the national life annuitants and Government tontines; but of their value, or of the accuracy with which they have been done, we are not prepared to speak, as we have been nowhere furnished with a clear statement of the materials he has collected, nor of the manner in which those materials were used. A considerable number of these tables, with their monied values, have been published by Mr. Finlaison in a Parliamentary paper or report upon the subject of life annuities.

A much more valuable and important addition has, however, been made to the statistical literature of the kingdom, by a publication of the Equitable Society in the year 1834, consisting of a singularly clear and accurate record of the rate of mortality among its members. It is accompanied by a curious and really interesting nosological table, which cannot fail to throw considerable light upon the doctrine of vital statistics, and which exhibits the proportion in which the different disorders prevail amongst mankind at different ages, in a very exact and curious manner,—added to which, Mr. Morgan, the compiler of these tables, has, at the expense of considerable labour to himself, furnished us with the rough materials from which his various conclusions have been drawn. The Equitable Assurance Society, one of the oldest of its kind, was first established in the year 1762, and these tables are brought down as far as the year 1829; in fact, going over an actual period of upwards of sixty years. The materials given in this publication, consist of the real numbers living, dying, and withdrawing from the society; but they have been very ingeniously adapted by Mr. Morgan, in the two tables which he has constructed, to an artificial radix, in order to simplify their arithmetical results. It is a curious circumstance, that these tables in their older ages approximate very nearly to the Northampton, and, indeed, in some instances, the mor-

tality of the Equitable is in excess; doubtless, when the experience of a few more years shall be added to the data of which we are already in possession, a greater similarity will be found to exist between these tables.

It must be remembered, that in the Equitable Society every assurer is selected from a mass of chosen lives in the middling and upper ranks. This may, in a great measure, account for the diminution of mortality during the early ages, and is in reality a still further proof of the exceeding accuracy with which the Northampton table represents the mortality of a mixed population. In addition to the tables already named, there are several others of great value, formed from observations on the rate of mortality amongst particular classes, in our own and foreign countries. Of late years, inquiries into these subjects have been much extended, and to that circumstance we owe our knowledge of a difference which has been found to exist in the relative values of male and female life. We must, however be satisfied with very briefly noticing the subject, as it would occupy too considerable a portion of our space and time, to investigate it as fully as it deserves. The rate of this difference has, of course, been very differently estimated; but, in round numbers, we may say that the value of female life exceeds that of male life, in the proportion of about eleven to ten. Some of the Assurance Societies, overrating the importance of this difference, have made a distinction in their charges for the assurance of the life of a male and a female. But in most offices, the number of assurances which are effected upon the lives of women are so few, that it is scarcely safe, and certainly not worth while to make the distinction.

FOUR CASES OF POLYPUS CURED BY LIGATURE.

Two or Three being Reported and Condensed, by MR. HENRY OLDHAM.

CASE I.

Elizabeth H—, aged forty-four, was admitted into Mary's Ward, in April 1833, under Dr. Ashwell. She is an unmarried woman, and has usually enjoyed good health. This was interfered with three years ago, by a profuse flow of the catamenia; succeeded by such irregularities in the performance of the function

as to induce the persuasion that it was about to cease.

These passive hæmorrhages were sometimes very copious; and not unfrequently a pint has been expelled at one gush. The character of this discharge changed about two years since, and assumed the appearance of coffee-grounds; becoming also more regular in its recurrence, and very offensive. This last peculiarity, however, was not constant: in the absence of a red discharge, there was one of a mucous kind.

She now complains of great lumbar pain, extending to the sacrum, with rigors, on the accession of and going off of the sanguineous discharge. There is no bearing down, nor pain on micturition; but she occasionally feels a mechanical obstacle to the free exit of the urine. She experiences a sensation of fulness about the vagina, and a distressing sense of weakness on making any exertion. Her countenance and general surface are sanguine; and though not absolutely emaciated, yet the flabby condition of her muscles indicates imperfect nutrition. The cerebral symptoms consequent on hæmorrhage are present, and the legs and ankles are oedematous at night. Dr. Ashwell examined, and entered the following report:

"I find a polypus attached to the fundus, about the size of a large hen's egg. The finger easily encircles its peduncle within the cavity of the uterine neck, and it extends half way down the vagina. Its structure is firm, and insensible to the scratch of a pin."

She was ordered to take tonics, and to maintain the recumbent posture; and in a few days, the polypus was noosed by ligature. The double canula was the instrument employed, furnished with a piece of whip-cord of suitable length and thickness. The patient was placed at the edge of the bed, in the usual obstetric position. The fore-finger of the left hand was passed over the enlarged portion of the polypus within the vagina, resting a little below the cervix. The canula was thus directed to the spot, and one of the tubes was carried round the polypus; and on regaining its fellow, was adjusted within the receiving tubes. The ligature thus applied was then tightened, and its free extremities twisted round the shoulders of the instrument. The patient did not complain of the slightest pain, but spoke of an obscure feeling of strangulation in the part. The ligature was daily tightened; and the vagina was occasionally

washed out with warm water. The polypus was separated, and came away with the instrument on the eighth day after the operation, appearing much diminished in size.

From the time the ligature was applied, there was no further discharge. The patient daily improved; and she was shortly presented, cured.

CASE II.

Jane J——, aged forty-seven, a single woman, of slim make, whose aspect and sunken features conveyed the external symptoms of malignant disease, was admitted into the hospital, under Dr. Ashwell, in August 1834.

Her health has generally been feeble; but, with the exception of several hysterical symptoms, it did not materially suffer until three years since: at this time, the catamenia, which had hitherto flowed naturally, became very profuse, lasting twelve or fourteen days, and attended by clots. A copious purulent and very fetid discharge succeeded this passive hæmorrhage, and alternated with the menstrual flow. With the exception of rather too profuse menstruation, she did not suffer from hæmorrhage during the growth of the polypus; but her present attenuated and very weakened state seems attributable to the purulent discharge, which continues unabated.

An examination was instituted by Dr. Ashwell, who reported:

"I find the vagina completely filled up by an insensible pyriform body, which almost protrudes through the external labia. The growth is encircled by the os uteri; but the finger can pass between them, excepting at the posterior part of the interior of the cervix, where the polypus is attached; and here the os is attenuated."

The bowels were regulated; and sulphate of quinine, in the compound infusion of roses, was administered. On the 27th of August, the polypus was tied; and when the ligature was tightened, the patient did not complain of pain. In the evening there was some abdominal tenderness, which probably arose from a distended bladder. The catheter was passed, and an opiate administered. She experienced no further suffering: the ligature was tightened daily; and on the 5th of September, nine days from the operation, the polypus was cut through, and with some difficulty, owing to the smallness of the vagina, withdrawn. It is worthy of remark, that the discharge ceased after

the polypus was tied, nor has it since recurred. Her general health rapidly improved; and she soon left the hospital, cured.

CASE III.

Mary Anne W—, aged thirty-five, the mother of three children, but now a widow, has been suffering the last two and a half years, from uterine hæmorrhage. This occurred, without any premonitory symptoms, in profusion; but has since been diminished in quantity, but constant. She is now the subject of anæmia; the surface being uniformly blanched; and her general health has been daily declining.

On examination a polypus was discovered, just protruding through the os, insensible to pressure. It was probably attached to the body of the uterus, as the finger could be passed round the cervix.

The loss of blood, which this patient was daily sustaining, determined Dr Ashwell to attempt to strangulate the polypus; but its very slight descent, and the unusual length of the vagina, frustrated the endeavour. On the evening of the same day, flooding occurred; the pulse was almost imperceptible at the wrist; the pupils contracted, and she appeared comatose. Active measures were employed to arrest the hæmorrhage; which was accomplished by plugging the vagina. She gradually recovered from this attack, and a longer instrument having been procured, the polypus was tied on the 4th of October.

No further hæmorrhage occurred, nor did the patient experience any pain, and on the eighth (four days after the operation) the polypus was cut through. This woman regained her former health and spirits, and left the Hospital quite well.

CASE IV.

Georgiana W—, aged thirty-four, was admitted Oct. 23, 1834. She is a delicate strumous woman, and was delivered of a six-months' child, ten months ago. For the last two years she had been supposed to labour under menorrhagia, and every variety of treatment had been employed without success. To arrest the hæmorrhage, she attended as an out patient at the Hospital, and the secale cornutum was administered, but as the discharge continued, she was examined. A large polypoid growth was discovered, partly protruding into the vagina, but encircled by the os and cervix, the former

of which was exceedingly attenuated. Scruple doses, repeated three times, of the secale cornutum were administered, with the hope of procuring a further protrusion of the polypus, and its release from the embrace of the os and cervix. This had the desired effect, and Dr. Ashwell tied it without difficulty. The catheter was passed for two days after the operation, which was not accompanied or succeeded by pain. Warm water injections were used during the separation of the polypus, which was accomplished in eight days' time. This patient recovered without a bad symptom.

REMARKS.

Of late, the opinion has been adopted by some eminent pathologists, that uterine polypi and hard or fibrous tumours of the uterus are nearly identical. I am disposed to believe that there are, occasionally, points of similarity, especially between large, old, and condensed polypi and these tumors; but it is erroneous to view this similarity as at all complete, or universally existing.

In *structure*, there is rarely as much induration and closeness of texture in the polypus as in the fibrous and fleshy tumor: in the latter there are generally to be found the white membranous lines transversing the tumor in every direction, and a hardness; forming together the diagnosis of scirrhous from other diseases. In the majority of polypi, with the exceptions stated above, there is a looseness, softness, and vascularity, clearly diagnostic of a different organization.

In *sensibility*, there is little resemblance between the two diseases; for while in the genuine uterine polypi, with scarcely an exception, there is an entire absence of sensation the hard tumor is by no means bereft of this property. A needle may be pushed into the former growth without exciting pain, but not so in the fleshy tubercle. One of the best distinctive marks of a polypus, is certainly its sensibility.

In *vascularity*, there is a wide difference. It is rare to meet with a large tumor that bleeds, while it is certainly very uncommon to discover a polypus from which the hæmorrhage is not frequent, and sometimes large and alarming. In a late volume of the *Medico-Chirurgical Transactions*, Mr. Langstaff adduces an instance where a patient lost her life from the repeated bleedings of an undiscovered uterine polypus. Nor are such occurrences rare.

In *locality*, they generally differ widely. The hard tumor most frequently grows externally, seldom encroaching on the cavity of the uterus. Allowing, what is perhaps true, that they have a common seat of origin, probably in the muscular tissue—while the tumor proceeds towards the walls, and, by its growth and bulk, mechanically interferes with the abdominal viscera—the polypus distends the mucous lining, and, whatever size it may attain, it continues to be invested by an increased growth of the same tissue. Thus in the majority of tumors, the peritoneum, a serous membrane, will form the external tunic, whilst the polypus is entirely covered by mucous membrane.

The *morbid processes* attendant on their progress are not similar: the tumor, when it destroys life, which is not common, does so by irritation of the system generally, and by inflammation and ulceration of proximate organs; rarely by ulceration in its own structure. The polypus, on the contrary, if undiscovered or neglected, induces a fatal result, most commonly by hæmorrhage, from vessels pouring out blood from its surface; and, occasionally, ulceration is present also.

The cases prefixed to these observations are not devoid of interest. In all, an examination had been neglected, till the symptoms were so urgent as to forbid further delay; so that unnecessary loss of blood, and to an injurious and alarming extent, was the result of this great practical error. In one instance there was no hæmorrhage, but a constant secretion of pus: nor does it appear that such a process was better supported than loss of blood; for J—— was more anæmiated, and had more of the malignant aspect, than any of the other patients. Excepting (in No. 8) where the polypus had only partially emerged from the uterine cavity, there was no difficulty in the operation; and even there, a longer instrument rendered the noosing of the growth easy and safe. In none of the women were there any after-symptoms, inducing solicitude or risk. In all, the hæmorrhage ceased immediately on the tightening of the ligature; nor did it again occur;—a tolerably good proof that the hæmorrhage arises from the growth, and not from the uterus;—a fact receiving additional corroboration from the attempt, by Mr. Sisbon and myself, to inject a polypus, an account of which, with a drawing of a section of the growth, is subjoined.

Two of the four women were single; a third had borne three children, and the

fourth, although long married, had never been pregnant.

It is scarcely necessary to say, that, in common with English practitioners, I prefer the ligature to the knife in the excision of polypi. I once removed a small polypus by the latter method, and the hæmorrhage was alarming, requiring the plugging of the vagina for its restraint. There are two preparations in Guy's Museum, of small polypi removed by incision; and it is recorded, that the hæmorrhage was extensive. This risk is avoided by the ligature, and in none of the numerous instances where I have used it, has there been any bleeding on the separation of the growth. No case has yet come to my knowledge of polypus occurring a second time in the same individual.

AN ACCOUNT OF THE POLYPUS INJECTED
AND EXAMINED BY MR. SISBON
AND DR. ASHWELL.

When first received, the polypus was exceedingly soft and pulpy, from putrefaction. By means of a blow-pipe, vessels running on the surface were inflated; but from the pulpiness of the mass, it was impossible to insert an injecting-pipe. Mercury was, however, thrown into the vessels, but when it had run for a very short distance, a vessel into which it had entered, and whose calibre it was distending, gave way; and although its further escape was arrested by gentle pressure, the injecting being continued, the mercury again burst forth at an adjoining part.

The polypus was now immersed in weak spirit for several days, and its consistence was then rendered much firmer. Mercury was again thrown in, by the pressure of a few inches of its own column, and although a great quantity escaped by the vessels terminating on the surface, yet a considerable number were filled.

The growth was rendered transparent by drying, that the injected vessels might be more easily distinguished. During the process, much of the mercury was necessarily driven out, through the numerous apertures on its surface. A section of polypus was then made, that the comparative vascularity of the surface and substance might be better observed.

The superficial vessel, which presented numerous anastomoses, varied in size, from a dimension little larger than a hog's bristle to that of crow-quill. They ran

in various directions, some of them having a convoluted appearance.

At the centre of the polypus there was a vessel, which originated in the peduncle, and ran in a straight direction for about an inch; when it had reached the bulb of the polypus, it became extremely tortuous in its course: it was about the size of a large crow-quill. There were several smaller vessels in the substance of the tumor.

PURULENT DISCHARGE FROM THE LINING MEMBRANE OF THE UTERUS.

Reported by Mr. JOSEPH RIDGE.

Marianne B—, aged 19, of florid complexion, ordinary stature, and sanguineous temperament, was admitted in July 1836, into Petersham Ward. She had been in service, and had enjoyed good health, until eleven weeks since, when she began to complain of uneasiness in the hypogastric region, with severe pain in the right groin, increased towards night. This was accompanied with a thick, yellow, and very fetid vaginal discharge, which has continued up to the present time. The catamenia have not been arrested; and they appeared a fortnight before her admission.

Her general health has suffered: she feels weak, and indisposed to exertion. There is a profuse purulent secretion, which comes on at intervals, especially after exertion. On getting out of bed, or in endeavouring to evacuate the bladder or rectum, it passes per vaginam, by gushes, being preceded by a cessation for some hours. Occasionally, it continues for two or three days together; and then ceases, until its accumulation is relieved by a sudden flow. She has lumbar pain, and occasionally a distressing sense of fulness and bearing-down in the uterine region. Sometimes the pains are severe and lancinating, extending to the pubes and groins: bowels costive: tongue slightly furred: pulse rather full, and moderate.

These symptoms continued for several weeks, but with partial amelioration. The purulent secretion was, at intervals, diminished; but soon afterwards recurred, in equal quantity. She passed over two catamenial periods; and the discharge appeared to be intimately mixed with the sanguineous flow. Some shreds of membrane were discovered, being preceded by more than usual pain.

The treatment consisted in the exhibition of laxatives, with occasional topical bleeding, and sedatives to allay constitutional irritation. An opium suppository was used, with a belladonna plaster to the loins. Injections of an astringent kind, variously modified, with the hip-bath, were employed, but with little advantage.

The obstinacy of the disease, and the marked debility accompanying it, determined Dr. Ashwell to inject the cavity of the uterus with tepid water. This was effected by introducing a gum-elastic catheter with an open mouth, the edges being smooth, within the cervix, and propelling the fluid through its tube. Considerable pain over the pubes followed, which was relieved by anodyne fomentations. The discharge greatly abated, and a second injection was ordered. This was followed by more severe symptoms, and marked evidence of hysteritis; which was relieved by bleeding, both general and local, purgatives, fomentations, and a strict antiphlogistic regimen. The discharge ceased with the cure of the hysteritis; and in a few weeks she was presented, feeling quite well.

REMARKS.

I was not prepared for so alarming an attack of inflammation, as the consequence of the injection merely of warm water; although in a case entirely similar, and cured by injection, sent to me by Mr. Morgan, hysteritis of marked severity followed the use of a very weak solution of the sulphate of zinc. The remembrance of this induced me to employ tepid water only. It is well known, that in extensive uterine hæmorrhage, and in menorrhagia, cold water, and water mixed with salt, may be thrown in the uterine cavity with impunity. But in these affections there is no disease of the lining membrane, which is doubtless present in the cases of purulent secretion. Thus it would appear, that morbid derangement of the mucous membrane of the uterus precludes the safe employment of astringent, and even of mild injections. In a former part of my communication, I have narrated the severe and dangerous results of an injection of a mild solution of zinc into an ovarian cyst; and it seems that similar risk attends a similar treatment, where the mucous linings of cavities are secreting pus. It must, however, be recollected, that a cure was obtained by this measure, in both instances of purulent disease of the lining of uterine membrane: and the question is naturally sug-

gested;—whether the risk is compensated by the probability of cure? It ought also to be a matter of some consideration, whether adhesion of the sides of the uterine cavity may not follow the inflammation necessary for cure.

ADHESION BETWEEN THE WALLS OF THE VAGINA, OCCASIONING RETENTION OF THE CATAMENIA.

Reported by Mr. HENRY OLDHAM.

Elizabeth R—, aged 22, a well-developed girl, of short stature, florid complexion, and fair skin, was admitted into Guy's Hospital in February 1836, under Dr. Ashwell.

At the Age of 15, she had some affection of the eyes; but with this exception, she enjoyed good health until ten months ago, when she first became troubled with headache, vertigo, and lassitude, a sense of fulness in the hypogastric region, with lumbar pain, capricious appetite, pain in the side, with irregularity of bowels, for which she was received into the hospital, under Dr. Cholmeley. At this time the catamenia had not appeared; and an examination was instituted, to ascertain if any mechanical obstacle existed. The parietes of the vagina, about two inches from the vulva, were found closely adherent; and the fluid could be detected immediately above. Mr. Key divided the septum; and a large quantity of dark-coloured, viscid fluid, was evacuated. The opening was dilated with bougies; and she shortly left the Hospital, feeling well. There was but one scanty appearance of the catamenia after this period; but her health was not materially deranged until six weeks of the present time, a white mucous discharge alone having occurred. A recurrence of the above mentioned symptoms induced her to apply to me for advice, and, on examination, it was found that the divided surfaces of the vagina had again firmly united, but that the catamenial fluid was accumulated in small quantity only, which was proved by the absence of a fluctuating tumor above the cicatrix. Finding her general health somewhat impaired, and the morbid sympathies of the uterus, such as sickness, headache, &c., continually present, I prescribed laxative medicines, mild tonics, nutritious diet, and palliative remedies, to remove urgent symptoms. The symp-

toms became more severe, as the quantity of menstrual fluid increased; and she was re-admitted into the Hospital, under Dr. Ashwell. At this time she complained of giddiness, headache, and tinnitus aurium, lumbar pains, with a sensation of fulness and bearing down, occasional dyspnoea, uncertain appetite, depression of spirits, and great irregularity of the bowels, sometimes being troubled with diarrhoea, followed by constipation. The uterus was not to be felt above the pubes, but a feeling of fulness, not of distinct fluctuation, was communicated to the finger, on examination. The same class of remedies were used, under which her general health improved; and in two months' time, the tumor above the united parietes was so distinctly bulging, as to warrant the evacuation of the retained catamenial fluid, which was less in quantity than on the previous occasion. In twelve hours after the operation, symptoms of peritonitis were present; which were met with active measures, such as bleeding, both general and local, purgatives, calomel, &c. They, however, continued unsubdued, and she died.

The body was conveyed to the mother's where an inspection was obtained.

On opening the thorax, marked traces of recent pleuritis were universally diffused. The lungs, in some portions, were found to adhere to the opposed pleura costalis, by delicate bands of imperfectly-organized fibrin, which were readily broken down. In other parts, layers of plastic lymph were found loosely attached to the pulmonary pleura, and within the pleural sac; on both sides there were three or four ounces of serous fluid, with some flakes of lymph floating in it. The depending parts of both lungs were gorged with blood and serum, which ran out from the two surfaces of a divided portion. The upper lobes were crepitant, but their edges too rounded. The heart and large arteries were healthy.

On opening the abdomen, layers of lymph were found on the surface of the liver, particularly around the acute margin, and between the convolutions of the intestines. This lymph varied in degree of firmness; appearing, at the under part of the liver, to be converted into a tolerably well-organized band of false membrane, attaching it to the opposed surface of peritoneum; in other parts it was plastic; and in the pelvis, some little flakes were seen, swimming in serous fluid. The mesenteric glands were greatly enlarged, and also those along the psoas

muscle and brim of the pelvis. Some of these were of a scirrhous hardness; others of a chalky consistence. Those on the brim of the pelvis were particularly enlarged, so as greatly to encroach on the dimensions of the superior strait. The uterus, and its appendages, had no contracted adhesions; both anterior and posterior pouches being entire.

The situation of the stricture was a little more than an inch below the os; and above this part, the vagina appeared thin and distended, forming a continuous line with the dilated os, the circumference of which was above four inches. The cervix rapidly became thicker; and, for upwards of three inches towards the fundus, the parietes were double their normal size. The upper half of the body of the uterus was somewhat more bulky than natural, and its cavity slightly increased. The broad ligaments were unaffected, but their appendages were much less delicate than natural. There was a cavity within the cervix, which formed the chief dilatation, so expanded as to be able to enclose a goose's egg. The rugæ and cells of the cervix were greatly diminished, and their surfaces presented a slight appearance of fibrinous effusion. Some few longitudinal striæ were visible, more particularly at the posterior part, apparently the result of a recently-contracted cavity.

REMARKS.

The preceding case confirms the opinion, that operations about the vagina and perineum are occasionally followed by inflammation of the peritoneum; and it ought to induce caution in the prognosis. The first division of the septum was not succeeded by mischief of any kind; yet, although there was no difference in the method of operating, a second incision through the parts led to a fatal attack of peritonitis. The distention of the cervix, while the fundus and body of the uterus retained their normal form and size, is singular; and corroborates the statements lately made as to the prolapsus of the neck of the uterus by stretching, and perhaps by growth, while the parts of the organ or viscus, above the cervix, remain in their original state. If, as this case proves, effused fluid may distend and stretch the cervix, independently of other parts of the organ, it is not difficult to conceive that the same result may occur from other causes.

PETITION FROM THE GOVERNORS OF THE COUNTY OF LOUTH HOSPITAL.

“TO THE HONOURABLE THE COMMONS OF THE UNITED KINGDOM OF GREAT BRITAIN AND IRELAND IN PARLIAMENT ASSEMBLED,

The Humble Petition of the Governors of the County of Louth Hospital,

“**SHEWETH**—That they observe with great regret that the concerns of hospitals and dispensaries are introduced into a bill now before your honourable house, the object of which is a compulsory establishment of poor laws for Ireland—laws which they would most gladly see in operation under due restriction.

“That they feel convinced a bill which would, in any way connect these institutions (at present so much dependent for their support and protection, on the contributions and superintendence of the possessors of landed and other property,) with such as shall necessarily be upheld altogether by parochial, or county assessment, must prove very detrimental.

“That they have further to observe that amongst those who now avail themselves of these institutions, there are very many who would be deeply injured by such an alteration in the present system of managing county hospitals, as should cause them to be classed with pauper or workhouse—persons too poor to meet the heavy expenses incident to disease or bodily injury, yet possessing a spirit, not illaudable, and a place in society, though humble, that would make them decline all aid that could subject them to be ranked amongst the number pronounced destitute. For the sake of this numerous class also, your petitioners would deprecate such alterations in these institutions as might occasion the breaking down of an honest spirit or injury to so large a body of our community.

“Your petitioners are not aware that the mode of insuring to the public a right use of the funds entrusted to the governors of hospitals has been ever found ineffective.—These meet quarterly, when all accounts are examined and audited, and the affairs of the house duly considered, and, if necessary, special meetings are held at the call of three governors. Annually the whole concerns of the institution are again brought before the governors. The treasurer's accounts properly

attested, together with a statement of the benefits which have resulted to the public by the relief of the sick and maimed are then duly forwarded to the government office appointed to receive them.

"It may be useful to show what are the effects of the present system, as they now appear in the hospital of this county, and how these institutions may suffer by a departure from it, as regards funds, guardianship, and its moral influence upon our community.

"The governors, by economy, having established a building fund to the amount of fifteen hundred pounds, made an appeal to the possessors of property of every description throughout the county, by which that sum became doubled; with this they erected a building, in all respects fit and proper for their purpose.

"There are seventy governors by subscription. During the last year there have been seven general boards, and the number who have personally visited the institution, during the same period, average three in each week.

"Your petitioners therefore pray, that a system capable of producing so much benefit in every way to these institutions, and to the public, may not be exposed to any alterations that could endanger their well doing, or interrupt the present course of private contributions to them.—Your petitioners will," &c. &c. &c.

LARVÆ IN THE HUMAN BODY.

At the last Meeting of the Entomological Society, a communication was read from Rev. L. Jenyns on the Larvæ of a Dipterous Insect, which was visited in very large quantities from the human intestines. The case was that of a clergyman, 70 years of age, whose first symptoms were general weakness, loss of appetite, and a tremulous motion in the intestines. The discharge continued for some months, and several quarts were passed alive, the chamber-pot being half full, sometimes accompanying the stools, and at other times being alone. The insects were evidently aquatic, and were supposed to be similar to those known as *Vermicularis Latrinarum*, of Swammerdam. Similar cases are described by Dr. Bateman, and in the Edinburgh Medical Journal where they were considered the larvæ of the *Musca Domestica*. Their length was about four and a half lines, the breadth one and a quarter, elongated in

the middle, and the body was composed of twelve membranous segments. No light could be thrown on the means by which they got into the body; but the first effects were felt in the spring of the year; they likewise being voided in summer and winter; but it was supposed they were hatched in the intestines, where they found plenty of nutriment. Dr. Bateman considered that such insects were taken in with the water, though it did not appear that such was the case in this instance, the patient never drinking water unmixed, and that which was used being taken from a pond with a clay-bottom. The insects were provided with an air tube and branchia, and were evidently of amphibious habits.

MEDICINAL SPRING.

A new and valuable discovery of a medicinal spring has recently been made at Greenford-place, near Harrow, which, in the opinion of the best judges, is really worth a trial. The circumstances under which this Spring was first discovered may be stated in a few words. In the summer of 1836 the proprietor happened to mention to a medical gentleman from town, who was paying him a friendly visit at the time, that although he had bored for water to a great depth, none could be found which was not so impregnated with saline matter, &c., so as to be totally unfit for domestic purposes. It occurred to the medical gentleman that it might contain medicinal properties, and he recommended to the proprietor to have it analyzed. This has been done by one of the first practical chemists in London; and from the analysis it will be seen that it contains qualities of no common order, and not often found in a natural spring in this country; for, besides being a pleasant and grateful beverage, its properties as a saline aperient render it a valuable medicine, and its mode of operation is both mild and efficacious. From the above statement, and from the subjoined analysis, it will be seen that this water possesses properties which a long experience has proved to be very efficient in the cure of many diseases. To those whose constitutions are impaired from a residence in warm climates, and to persons whose digestive powers are weakened by sedentary habits, close attention to business, or late hours, a course of this water will be found highly beneficial, by

producing a salutary action on the various secretory functions.

Salts, &c., found in an imperial pint of water, as analysed by J. T. Cooper, sen., Esq.—(Cubic inches) 4·5 Carbonic Acid; 1·0 Nitrogen; (Grains) 40·76 Sulphate of Magnesia; 24·76 Sulphate of Soda; 4·61 Chloride of Sodium; 2·95 Chloride of Lime; 3·03 Carbonate of Lime; Hydrodate of Iodine, a trace.

FAMILY CORRESPONDENCE.

My dear Son,—We were all enjoying our tea and coffee, when your last letter came to hand, and I read it aloud; but when I had finished—"obstupui!"—your dear and anxious mother could scarce speak,—"*vox faucibus hæsit!*"—as for your poor old aunt Sarah, who, with the assistance of her patient ear-trumpet, heard only one fourth of your misfortunes,—"*tremor occupat artus!*"—and our worthy reverend pastor, Doctor —, who dined with us, could not help (*ab imo pectore*) exclaiming,

"— *Quid non mortalia pectore cogis, Auri sacra fames!*"

For God's sake do not, in future, be so precipitate in your metropolitan medical movements! What *could* have induced you to enter to such a place as the Charing Cross Hospital, without making some enquiry beforehand about the abilities and characters of the medical officers connected with it? You have had, in all our opinions at home, a most miraculous escape!

I never heard the name, until you mentioned it, of the Charing Cross Hospital; but from the confidential description you have given me of the place, particularly of the beautiful *PRIVATE RESIDENCE* which is attached to it, and which was built at the expense of a charitable public, I have little doubt but in a very short time, the institution of Charing Cross will become very *notorious*. There certainly is something strange, as you say, in having such a *beautiful private family residence*—replete with every accommodation—the property of the charitable governors of the Hospital—and occupying one of the best situations in London, either for a *private or professional residence*, remaining unoccupied; whilst appeals are making, at least once a month, by sermons for money to support the unfortunate in-

mates of the Charity. From what I know of London, such a house would bring a rent of £150 a year at least, and when other parts of the Hospital are converted into shops, which no doubt turn in a good yearly income, I confess that I am very much surprised that this *beautiful private residence* has not been turned to some account before now!

Under all the circumstances, it appears to me that the *learned and upright* individuals, who compose the Council of the *Royal College of Surgeons*, acted a very questionable part in recognizing the practice of the Charing Cross Hospital, and again almost immediately withdrawing the *recognition*. To say the least, the conduct of them was very vacillating, and can only be excused by supposing that some daring misrepresentations had been made to the Council, by those interested in the sale of certificates, to the inexperienced young men like yourself, who might have been induced to enter there. I must certainly give you every credit, for the great clearness you have displayed in getting nearly all your money back.

I would now, my dear Tom, advise you not to delay a moment in seeing the hon. member for Finsbury, or if he be too much engaged with his constituents, surely there are some other of your friends, who are equally well acquainted with the history of the London Hospitals, and who would direct you what to do in your present predicament; at all events do not act upon your own judgment solely. I am told that the *NORTH LONDON HOSPITAL* is a very superior one, and that the physicians and surgeons attached to it, not only give their time and trouble to relieving its unfortunate inmates, but they actually give, for the support of the institution, all the fees they extort from the pupils who attend their invaluable practice. I confess to you I am very sceptical about the truth of this; but if such be *really* the case, I would have no hesitation in *insisting* upon your entering there immediately. It has always been my opinion that, in our public capacities as medical men, we are called upon to minister to the poor, as far as in us lies, without fee or reward; and so convinced am I of this, that were I called upon to give extreme examples of the degradation of human nature, I would point to those individuals who lived by converting the infirmities and ailments of "sick and needy" fellow creatures to their own sordid purposes. If, then, the *North London Hospital* can boast of such transcendent ex-

amples of philanthropy and generosity in the persons of its physicians and surgeons, it must justly, in my opinion, hold the highest eminence amongst the metropolitan charities of the United Kingdom, inas much as its truly benevolent medical officers can have no sinister purposes to serve in soliciting the attendance of the pupils at large to their practise, when all the fees received from those very pupils who enter, are devoted to the Christian shrine of UNIVERSAL BENEVOLENCE and TRUE CHARITY. It is for these reasons I am anxious for you to enter to the practice of the North London, but before doing so make every inquiry, for what I now you is mere report: I shall leave to your own judgment the school you had best enter to; do not however be led away by the impudent puffs which appear in the papers; the men who resort to this kind of notoriety can have but little to recommend them.

Were I placed as you are, I would first attend a few lectures of each teacher, and judge accordingly. Make my respects to your chum, Mr. SCOTT Macdonald, and let me hear from you soon. Say if you want any more money; all join in affectionate love.

Ever your dear father,
PETER ———.

*Blarney, Kilbally macalogue,
January 1, 1837.*

P.S.—When you call upon the hon. member for Finsbury, you may read this letter to him, and endeavour to direct his attention to that portion of it which relates to the BEAUTIFUL PRIVATE RESIDENCE, which is attached to the Charing-Cross Hospital, and which was built by MONEY COLLECTED FOR CHARITABLE PURPOSES, as such places have always particularly interested him, as I hope this will also.

My dear Father,—I just received your letter, and have only time to say, that I have entered to the MIDDLESEX HOSPITAL. I heard enough of the NORTH LONDON HOSPITAL, to decide me in having nothing to do with it. You shall hear all about it in my next. I have not yet entered to any school. Send me some money as soon as possible! The postman's bell is ringing so, dear father, with love to all at home,

Ever your affectionate and dutiful son,
THOMAS ———.

P.S.—I shall write you a long letter

soon. My friend Sandy tells me most extraordinary things about the KING'S College. He is thinking of purchasing a dressership at St. BARTHOLOMEW'S or GUY'S.

*London, Great Russell-street,
January 7, 1837.*

COURT OF KING'S BENCH.

DUBLIN, FRIDAY, JUNE 9.

*The King v. Mostyn and eleven others,
Members of the Corporation of the
Sligo Fever Hospital.*

Justice Burton delivered judgment in this cause. The learned judge recited the statute of the 58th George III., cap. 47, which regulated medical charities, and it appeared that the power of election lay with the members who had subscribed a guinea each, or such sums as were equivalent to constitute life members. A vacancy occurred, and two gentlemen became candidates—one of them was elected by a majority of votes, the other disputed the appointment on the grounds of informality and impropriety in the election, and that the twelve members were not qualified to vote, according to the terms of the act, and accordingly applied for a *mandamus*. After entering at length into the law of the case, the learned Judge concluded by refusing the application, with costs.

EXCESSIVE GROWTH OF HAIR.

Backstrom relates the case of a Prussian woman, whose hair extended beyond the sides of her bed, and she was in the habit of turning it over to make a quilt. Caligerus saw a man in Copenhagen, whose locks were six feet three inches in length, while the hair of a woman measured six ells.

NEW MODE OF ADMINISTERING SENNA.

A singular preparation as a purgative for females and children is recommended in the *Bulletin general de Therapeutique*, as one admirably adapted for the completion of its object, without inducing nausea or disgust. An infusion of senna is to be made in water, and allowed to stand all night. The liquid is to be filtered in the morning, and employed, instead of water, in making a cup of coffee, to which a proportionate quantity of milk, &c. should be added. It is said that the taste of the senna will not be perceptible.

BOOKS FOR REVIEW.

A Selection of Latin Prescriptions according to the Nomenclature of the Pharmacopœia Londinensis, 1836, for the Use of Medical Students. By George Folvoje, author of a Literal Translation of Celsus, &c. London, 1837.

Observations on the Prescration of Health in Infancy, Youth, Manhood, and Age, with the best means of improving the Moral and Physical condition of Man. By John Harrison Curtis, Esq. &c., &c. 12mo. London, 1837. Renshaw.

A most instructive work for the general reader.

The Student's Pocket Guide to the College of Surgeons. By Forbes Winslow, Esq. J. T. Cox.

A Manuel of Practical Midwifery, including the Diseases of Women and Children, in accordance with Burns, Denman, Gooch, Dewees, Blundell, Davis, Ryan, &c. By Forbes Winslow, Esq., M.R.C.S.

An Introduction to Medical Botany, comprehending the Elements and Glossology of Botany—the Linnean, Artificial, and Natural Systems—the Natural System of Jussieu, and several comprehensive Tables of the Properties, Uses, and Doses of Medicinal Plants. Illustrated with coloured figures. By Thomas Castle, M.D.F.L.S., &c., &c. 12mo. pp. 276. E. Cox.

An excellent Manuel for the lovers of Botany.

A Translation of the Pharmacopœia Londinensis, with descriptive and explanatory notes on the Materia Medica, &c. By Thomas Castle, M.D. 12mo pp. 260, E. Cox.

A very correct translation.

The Teeth a Test of Age, considered with reference to the Factory Children. Addressed to the Members of both Houses of Parliament. By Edwin Saunders, Fellow of the Medico-Botanical Society, &c. London, 1837, 8vo. pp. 76. Renshaw

Rudiments of Physiology. By Dr. Fletcher. Part III, On Life, as manifested in Sensation and in Thought. Edited by Robert Lewins, M.D. F.R.C.P.E. With a biographical Memoir of the Author. Edinburgh, 1837, 8vo. pp. 144. Carfrae and Son.

TO CORRESPONDENTS.

Caustic's assertion will require further proof. Well prepared as the profession may be to give credit to any fraudulent measure of the whole body of the Council, we are unwilling to believe that any individual member would have the boldness to have his eyes blinded with a five pound note, to prevent him seeing the age of the candidate. The College are quite aware that false certificates of the birth of candidates, as well of the attendance at lectures, are by no means unusual.

Cadaver—Dr. James Sommerville was indebted to the (*certificates*) both of Sir Astley and Sir Benjamin, for his office of Inspector of Anatomy. The learned doctor had actively assisted Sir Benjamin in forming his pathological collection, for which Sir Benjamin declares that he paid the doctor handsomely, in addition to getting him the Inspectorship.

A Subscriber at Carlisle and others.—The Index will appear immediately.

A Glasgow Correspondent.—The Metropolitan University has not as yet published its regulations for degrees.

Medicus.—The information about the German degrees will be given at a personal interview.

M. R. C. S.—The information will be given on a personal interview.

M. P.—The communications on Diseases of the Ear will be readily received by another hebdomadary. We cannot really state terms on authority. An application ought to be made to the quarter.

Chirurgus.—We believe the fee demanded by a *ci-devant* liberal Surgeon, for attendance on his medical brethren, is only one-half the ordinary charge. The terms to visit Cobbett were not agreed on.

Argus.—The information was not correct. There were only two of the Gower-street students rejected on last Monday. The other nine students passed at the three tables, which made three at each table; and there are three examiners at each of the three table, making nine in all.

A. S. will be likely to meet with employment in writing communications to certain Journals, by applying (all letters post paid) addressed to A. B, care of the House Surgeon, North London Hospital.

All communications and works for review to be forwarded, (carriage paid) to Dr. RYAN, 4, Charlotte-street, Bloomsbury-square.

London Medical and Surgical Journal.

4. Eyes.—The eyes do not close in paralysis, apoplexy, asphyxia, and the Hippocratic countenance. An open state of the eyes is therefore considered a very bad sign. In tetanus the eyes are generally open, both when asleep and when awake; for neither the sphincter (orbicularis palpebrarum) nor the levator palpebræ superioris is completely relaxed, so that the eye-lids are always partially separated. The ball of the eye is fixed in this disease, from the contraction of the recti muscles. Ptosis is a palsy of the levator palpebræ. Strabismus occurs in the first stage of apoplexy, in myelitis of the upper part of the spinal chord, in amaurosis, in worms, &c. It takes place either from defective action of one set of muscles, or from increased action of another set. The direction of the eye is upward in tetanus, because the inferior oblique muscle acts too much; and in paralysis and syncope because the superior oblique acts too little. The eye is too

moist in tetanus and the last stage of ophthalmia: it is dry in the first stage of ophthalmia, in phrenitis, and in all diseases of debility. It appears to "flash" in anger, mania, hysteria, and fever. The cause of this appearance is, that the vessels are dilated, and admit more white blood; so that more light is reflected. The iris is confidently said to be convulsed in epilepsy. I never saw it, nor any one who had; and we are not sure that the iris is muscular, so as to be capable of being convulsed.

5. *Tongue*.—The tongue is flat, and the anterior extremity rounded in gastroenteritis; it is cylindrical and pointed in hectic fever. It is in the latter that the lobster-tongue (red with white papillæ) sometimes occurs. In scarlatina it is white with red papillæ. In dyspepsia, especially in the morning, the tongue is rough and scabrous. The tongue goes to the diseased side in paralysis of one side of the face, being turned in that direction, as on a pivot, by the action of the genio-hyo-glossus muscle of the healthy side.

6. *Skin*.—The skin is pale, rough, and dry (forming the cutis anserina) in the cold stage of fever. It is pale, but not rough, in syncope. In the hot stage of fever it is red, and its temperature is likewise much raised, especially in scarlatina. Currie says that the highest point to which its temperature rises, is a hundred and *twelve* degrees; Home, says a hundred and *seven*, and Gregory fixes it at a hundred and *four*. The skin is yellow in jaundice, and in yellow fever. It is blackened, sometimes from the internal administration of nitrate of silver. Dr. Hope says this is occasioned by the nitrate of silver being decomposed by the perspiration, and forming muriate of silver. But if this were the case it would happen more frequently. The skin is of a green colour in chlorosis. It is dry in diabetes and dropsy. It has an acid odour in miliary fever; and in ramollissement of the brain its odour resembles that of a mouse.

7. *Skull*.—The precocious abilities which are often exhibited by children afflicted with rickets, are probably owing to hypertrophy of the brain, occasioned by the bones of the skull giving way.

II. *Physiological symptoms*.—These comprehend alterations from the disease in the various functions of the body, particularly in the processes of respiration, circulation, digestion, and secretion; and in sensation, thought, and voluntary motion.

1. *Alterations in Respiration*.—Expiration is never difficult, but inspiration may be vitiated either from excess or deficiency of the natural stimulus, from a defective conveyance of that stimulus, from imperfect mechanism, or from obstructed air-passages.

(1.) Altered stimulus of the blood occurs in exercise and in the hot stage of fever; in both of which cases the lungs have too much blood to transmit. There is too little stimulus in syncope, and the stimulus is irregular in palpitation of the heart, and various diseases of that organ.

(2.) Defective conveyance of stimuli takes place in diseases of the spinal chord, rachitis, myelitis, and the end of apoplexy: for in the latter case, the patient dies of asphyxia. The same is probably the case in asthma, for Wilson Philip says it is from a defective supply of stimulus, and not from increased action or spasm. Dr. Duncan is of the same opinion. Division of the pneumogastric nerve (par vagum) has the same effect.

(3.) Imperfect mechanism is seen in adhesions of the pleura, and in ossification of the costal cartilages; likewise in the case of fractured ribs, in pleuritis, pleurodyny, inflammation of the diaphragm and angina pectoris; which is probably owing to spasm of the diaphragm.

(4.) The air-passages of the lungs may be obstructed, either by secretion within themselves, or by a secretion outside, which compresses them, or by causes which compress the whole lung. These causes are croup, laryngitis, bronchitis, hæmoptysis, tubercles, anasarca, pulmonary apoplexy, a vomica, hydrothorax, pneumothorax, &c.

Rhonus occurs in apoplexy and coma. Suspirium, or sighing, takes place in all congestive diseases; from fatigue and hunger, in diseases of the diaphragm, in the first stage of fever, and particularly in miliary and eruptive fevers. Ossitatio, or gasping, is a major kind of sighing, and is observed in the same cases; they are both occasioned by the venous circulation being retarded. Singultus, or hiccup, is observed in dyspepsia, diaphragmitis, diseases of the spinal marrow or nerves, in incipient phrenitis, and in gangrene. Hooping is the characteristic symptom of pertussis. Sternutatio, or sneezing, is frequent in the setting in of catarrh and the measles. Before increased secretion we have diminished secretion; and the mucous membrane not being defended by its natural secretion, the air becomes too great a stimulus to it. This

explains the occurrence of hot tears in ophthalmia; and of ardor urinæ in gonorrhea.

In all fatal cases of disease, death at last takes place from asphyxia; for as long as the respiratory system goes on, life continues. Hence the tuber annulare, or summit of the respiratory columns of the spinal marrow, is said to be the arx vitæ or citadel of life.

The voice is changed in laryngitis. It is hoarse in ulceration of the larynx, and in ossification of the cartilages. Susurration, or whispering, is heard in diseases of the recurrent nerve, in aneurism of the aorta, and in all cases in which pain is felt on moving the muscles of the larynx. Gemitus, or groaning, is a sign of great pain, and screaming of still greater, but the latter is sometimes uttered when there is no pain at all; as in hydrocephalus, where it is the consequence of spasm. Fletus, or weeping, occurs in hysteria and various other cases. When violent it is attended with a convulsive action of the larynx, diaphragm, and abdomen.

Under the head of alterations from disease in the process of respiration, we are to consider the various signs afforded by the stethoscope. These may be grouped under three heads:—1. Altered sound of respiration, which may be either defective, puerile, tracheal, or metallic. 2. Rales, which may be either sibilous, sonorous, mucous, or crepitating. 3. Alterations in the voice; including bronchophony, pectoriloquy, egophony, and metallic tinkling.

(1.) Altered sounds of respiration are of four kinds:—1. Defective murmur. This takes place in hepatization of the lung, in pulmonary apoplexy, in pulmonary oedema, in some stages of bronchitis, in tubercles, and in all cases where the lungs are rendered impervious in any part. 2. Puerile respiration takes place in certain portions of the lung, whenever the respiration is deficient in other parts. The quantity of air received in the portions which remain pervious, is greater in proportion to the part of the lung which is useless; so that the air gets more quickly to the air-cells, and consequently with greater impulse. 3. The respiration is said to be tracheal when the sound natural to the trachea, is heard in other parts of the lungs; as in hypertrophy of the bronchia, and in the case of vomica. 4. Metallic respiration is caused by the air passing through a liquid contained in a cavity. It sounds like a pin striking on a glass.

(2.) Rales. These are of four kinds:—

1. Sibilous rale; this is caused by a partial obstruction of the air-passages, from the secretion into them of a thin saline mucus; over which the air whistles. It occurs in the early stage of bronchitis. 2. Mucous rale; this is occasioned by the air passing through mucus of a thicker consistence, and is heard in hæmoptysis, phthisis, and the second stage of bronchitis. 3. The crepitous rale occurs in the first stage of pneumonia; in which it is occasioned by difficult dilatation of the air-cells, owing to effusion into their parieties. It also attends dry emphysema of the lungs, being caused by the motion of the effused air. 4. The sonorous rale is caused by the air passing over the thickened mucous membrane of the bronchial tubes. It is best heard in chronic bronchitis.

(3.) Alterations in the voice. The alterations in the voice, detected by auscultation, are likewise of four kinds:—

1. Resonance of the voice is heard in cases in which the natural sound, or tremor, produced in the lungs when the patient speaks is louder than usual, as conveyed to the ear by the stethoscope. It results from a portion of the lungs being a better conductor of sound than usual, owing to its solidification. 2. Egophony is sometimes heard when the pleural cavity contains a thin stratum of fluid, which compresses the lungs; as in hydrothorax, and the first and last stages of empyema. It is not present in hæmorthorax, because the effused blood coagulates. 3. Pectoriloquy is the reverberation of the voice in a cavity of the lungs. 4. Metallic tinkling is heard in cases where a fistula exists between the cavity of the pleura, and a phthisical cavity in the lungs; and a drop of matter passes while the patient is speaking.

Alterations from disease in the temperature of the body, fall under the head of alterations in the process of respiration. The heat of the body is increased in inflammation and the second stage of fever. It is diminished in the first stage of fever, syncope, morbus ceruleus, paralysis, dropsy, asthma, diabetes, asphyxia, gangrene, and all cases of impeded circulation.

2. *Alterations in Circulation.*—These arise from changes in the ordinary stimuli to the action of the heart, as in syncope; or from the addition of preternatural stimuli, as in palpitation; or from changes in the organic condition of the heart. In the natural state of the system,

the heart has two stimuli; one from the blood, and the other from the brain. These may be either increased or diminished, or a new one may be added. In the latter case the pulse becomes quick, hard, and weak, forming what is called a "wiry pulse." It is very well marked in peritonitis, the new stimulus being sympathy with the inflamed peritoneum. The weakness of the pulse depends on the small supply of blood; its quickness, from the heart acting on this small quantity of blood, owing to the preternatural stimulus; and its hardness is from the heart's acting violently. Hence the three qualities go together. In apoplexy, where one of the usual stimuli (that of the brain) is cut off, the pulse is slow, soft, and full. The two kinds of pulse we have mentioned form the extremes, between which there are many varieties. Indeed, it is said that every disease of every organ affects the pulse differently, so that in some countries (Japan, for instance) they draw their diagnosis from the pulse alone. In such cases, the characters of the pulse are divided into two groups, critical and organic; the first showing a crisis of the disease to be at hand, the others pointing out the organ affected. These symptoms are subdivided into superior and inferior; the first of which relate to organs above the diaphragm; and the last to those below it, and these are again subdivided according to the different organs.

Besides the characters already mentioned, the pulse may be irregular or intermittent. In the case of some individuals, the pulse is intermittent during health, and if a fever occurs, it becomes regular. Galen wrote nineteen chapters on the pulse, though he did not know its cause. The latest author on the pulse is Rucco.

With respect to the stethoscopic phenomena of the heart, there may be either increased or diminished sound. The other signs furnished by auscultation, are the *flatus follis*, *atritio limæ*, and *crepitatio corii*. The impulse is greater than it ought to be in hypertrophy of the heart, and the sound is greater in dilatation. The *flatus follis*, (*bruit de soufflet*, or bellows-sound) often indicates merely a functional disease; the *atritio limæ* (*bruit de rape*, or a sound of a saw) indicates organic disease; and the *crepitatio corri* (*craquement de cuir neuf*, or crackling sound of new leather) is a symptom of pericarditis.

3. *Alterations in Digestion.*—These

comprehend difficulty of swallowing, as in hydrophobia; ruminating and vomiting, which are symptoms of dyspepsia, constipation, diarrhoea, flatulence, &c. Hydrophobia is, I think, a convulsion of the gullet. It has been attributed to inflammation of various parts; but though various inflammatory appearances have been found in fatal cases of hydrophobia, none of them are essential to it. In the same way, hooping cough has been referred to inflammation of the bronchia, and dyspepsia to inflammation of the stomach; but such views as these would cashier functional diseases altogether. Inflammation of the bronchia and of the stomach may take place in the course of hooping cough and dyspepsia, but it is from a weak organ suffering from a general disease. Hydrophobia is evidently a functional disease, beginning with convulsions of the throat, and extending at last to the whole body. It may then give rise to inflammation of some organ. In the same way gastro-enteritis, probably, cannot occur without dyspepsia; but the converse is not true, for dyspepsia may occur without gastro-enteritis. I think dyspepsia arises from debility of the muscular action of the stomach. The stomach has three stimuli; its contents, the brain, and sympathy with other organs. If the stimulus of sympathy be cut off, owing to diseases of other organs, the stomach has only two stimuli to act with, and therefore becomes dyspeptic. The same result will follow from diseases of the pneumo-gastric nerve, which incapacitate the latter for the conveyance of the natural stimulus. The same effect, and for the same reason, is produced by the division of this nerve. When the stimulus of the brain is abstracted in consequence of apoplexy, large doses of purgatives are required to act on the intestinal canal. Vomiting may arise, either from the direct irritation of the contents of the stomach, or from the sympathetic irritation of the disorders of other organs. Most diseases are attended by dyspepsia, owing to the intimate sympathy of the stomach, with all the other organs of the body.

Deglutition is impeded in paralysis of the *œsophagus*, in *scirrhus*, stricture, inflammation, and spasm of that canal and in tumours. We distinguish *scirrhus* of the *œsophagus* from *erythematic inflammation*, by there being no increase of pain on swallowing, in the former case; by *scirrhus* generally attacking the aged, and usually the inferior part of the *œso-*

phagus, and by its being more chronic in its progress. A tumour is to be distinguished by a bougie. If it be moveable, it is a polypus; if not, it may arise from bronchocele, aortic aneurism, or some other affection, of which there will be the general symptoms. Paralysis of the gullet is to be distinguished from spasm, by there being no effort to swallow in the former, while the effort is vain in the latter; and by the former following apoplexy, while the latter follows spasmodic diseases. Paralysis is constant, is unaffected by the mind, and allows solids to be more easily swallowed than liquids; spasm is not constant, is much affected by the state of the mind, and allows liquids to be more easily swallowed than solids. In spasm we cannot pass a bougie, in paralysis we can. In the latter, galvanism is useful; in the former, opium.

4. *Alterations in Secretion.* — The odour of the breath is remarkably altered in insanity, owing to the halitus of the lungs being vitiated. Many other secretions of the body are vitiated likewise. This probably arises from the abstraction of the permanent stimulus of the brain; and the same vitiation of the secretions, and from the same cause, takes place during sleep.

If there be suppression of any secretion of the body, it indicates a constriction of the vessels concerned in that secretion. This causes an irritation, by means of sympathy, of other parts of the body, and leads to a vicarious discharge. The converse of this explains the vicarious suppression of other secretions, if one be in excess; as in diabetes, dropsy, &c. I should think that chlorosis was merely dyspepsia causing suppression of the menses, and not that suppression of the menses causes chlorosis.

5. *Alterations in Sensation.* — The senses are too acute in hysteria, phrenitis, the hot stage of fever, &c. They are too dull in coma, apoplexy, asthma, the first stage of fever, and in all diseases in which cold predominates. They are irregular in mania, hypochondriasis, and nervous diseases. Increased sensation leads on to spasm, and diminished sensation to paralysis. Lesions of sensation are of two kinds. 1. Morbid increase or diminution of the natural sensations, as nyctalopia, hemeralopia, &c. 2. Sensations entirely preternatural, whether proper to certain organs, or common to all. We shall consider the principal morbid sensations in detail.

(1.) Vertigo is intermitting sensation and thought. It may be called a convulsion of sensation.

(2.) Tinnitus aurium is felt before apoplexy, after epilepsy, and before and after all diseases of the brain. It is owing to the unequal circulation of the blood, which gives rise to too much blood, or too rapid a circulation of it in the parts lining the ear. It is the same cause which gives rise to muscæ volitantes, tingling of the teeth, formication of the skin, tenesmus, strangury, &c. The difference of these sensations is owing to the specific sensibility of the parts in which they occur.

LECTURES ON SURGERY.

BY JOHN HUNTER, F.R.S.

Of the Heat of Animals.

When the external heat is so much diminished that it does not assist the natural powers of an animal, and it is obliged to vary its proper standard and become colder, then many of the actions are either lessened or totally suspended, not being necessary: generation is suspended, and insensibility takes place, commonly called sleep; but it is not sleep. Sleep is an effect which takes place in all degrees of heat and cold, though when a man is asleep he is colder than when he is awake, and I find in general the difference is about $1\frac{1}{2}$ degree, sometimes less. This difference in the degree of heat between sleeping and waking is not the cause of sleep but the effect; for many diseases produce a much greater degree of cold in an animal, without any tendency to sleep. Besides, many of the operations of perfect health are going on in the time of natural sleep, at least in the perfect animals, as digestion, secretion, &c., while none of these operations are going on in the tribes called sleepers during their torpid state. In these animals, where a great many actions are suspended, it appears an effect arising from a certain degree of cold acting as a sedative.

Now this degree of cold in some cases seems to act as a stimulant: the animal powers are roused to action for self-preservation. It is probable that most animals are under this influence of cold, and that every order has its degree of cold in which many of their actions can be suspended.

In some countries, where there is summer and winter, there are some animals

whose actions are suspended during the winter. This suspension of several of their actions seems natural to them, being part of the œconomy of such animals. In other animals, where a suspension of several of their actions takes place from cold, it seems a force on those actions, as it rather seems to lead to the destruction of the animal than the preservation of life. We cannot give a stronger instance of the forcible power of the suspension of actions in animals from cold than what happened to Dr. Solander and others in their voyage round the world.

Returning from a hill in Terra del Fuego, they were suddenly surprised with a degree of cold beyond what they ever felt before. Dr. Solander advised that they should immediately make their way to the ship as fast as possible, and he himself would bring up the rear. However unnecessary it might appear, Dr. S., who had crossed the mountains in Switzerland, well knew the danger of being left, and told them that they would soon be attacked with an almost irresistible propensity to sleep; that whoever gave way to the feeling would sleep, and whoever slept would die. But after this very serious caution, the doctor was the first who felt the sensation he described, and could scarcely be persuaded by the united efforts of Mr. Banks and the others to proceed. Mr. Banks's black servant, Richmond, was the next whose desire of sleep was very great, so much so that, notwithstanding the consequences, he begged that he might be left to die. The doctor only begged to sleep a little, and promised that he would then proceed. Mr. Banks, finding the case grow more serious every moment, sent forward four of the company to the first place where they could light a fire, the rest staying and endeavouring to bring up the few who had laid down. The Doctor was awakened, but their efforts were less successful on poor Richmond. In the midst of their endeavours to rouse him, they felt the same symptoms stealing on themselves very fast; it was in vain to attempt carrying, every one being scarcely able to carry himself. Having proceeded about a quarter of a mile, they met two of their party with the welcome news of a fire being kindled at the distance of half a mile. These two were dispatched in search of Richmond. Having warmed themselves, and becoming apprehensive for the fate of the two, a party set off in search of them. They had missed their way, and become victims to the malady

from which they had endeavoured to restore the black. Richmond was found just crawling, and brought back, but no means had the least effect on the other two.

Winter.—I took two hedgehogs, not full grown, from their huts: the weather for some days preceding had been severe and frosty; the heat of the atmosphere was 44 degrees. In one the thermometer was introduced at the pelvis, and the mercury stood at 45 degrees; and at the diaphragm at 48 degrees. In the other I found the heat in the pelvis 46 degrees, and at the diaphragm 50 degrees.

The degree of heat of these animals being so low, it was compared with the heat of a puppy. The heat of the atmosphere during this experiment being 50 degrees, a thermometer was introduced into the belly and pelvis of the puppy; the mercury stood at 102 degrees, and also at the diaphragm.

Summer.—Atmosphere at 78 degrees. A thermometer was introduced into the belly of freshly caught hedgehog. In the pelvis the mercury rose to 95 degrees, at the diaphragm to 97 degrees.

From the foregoing experiments we find that the temperature is allowed to fall lower than the standard, which is productive of no evil excepting suspending such functions as require the standard degree of heat for their actions.

Animal matter endowed with the living principle, whether endowed with action or not, or whether of the first or second order of animals, as far as I am acquainted, admits of the temperature going somewhat lower than would serve for the congelation of the same matter in a dead state.

The more imperfect animals vary their heat according to the atmosphere in some degree.

I made the following experiments on fowls, which I considered to be one degree below what are commonly called quadrupeds.

I introduced the ball of the thermometer successively into the rectum of several hens, and found the mercury at 103 degrees, 103½ degrees, or 104 degrees. Cocks furnished the same results. In hens during incubation the heat was the same. Living eggs under the same hens raised the thermometer to 99 degrees; an added egg only to 97 degrees. So that the living egg had some power of generating heat. In the more perfect animal, as the fowl, the heat is not allowed to come so low as in the more imperfect.

The power of generating heat keeps the higher animals as near one standard as possible; but it was not necessary that this standard should be very exact, therefore we find that they are in some degree influenced by external heat and cold, somewhat similar to inanimate matter and the more imperfect animals.

As parts recede from the common mass, as extremities, fingers, toes, the combs of cocks, &c., they are more subject to be affected by cold, and will raise or sink the thermometer in some measure according to the external degree of heat or cold applied; though not in a proportional degree to this application, as would be the case in inanimate matter.

I put the ball of the thermometer under my tongue, and kept it there for some minutes, when it rose to 97 degrees, but would not go higher. I then took several pieces of ice and put them in the same situation, allowing them to melt. This I continued ten minutes, and found on introducing the thermometer that it fell to 77 degrees, and gradually rose again to 97 degrees.

I thought the urethra would do still better, and I introduced the ball of a thermometer into a man's urethra. At one inch from the extremity the mercury rose to 92 degrees, at two inches to 93 degrees, at four to 94 degrees; at the bulb of the urethra it rose to 97 degrees. Thus we see that projecting parts are subject to have their heat lowered by surrounding cold.

To render this experiment more conclusive, I endeavoured to render this part colder by applying a colder medium to the penis than the common situation. This part was immersed in water at 65 degrees for a minute. The thermometer, introduced an inch and a half, rose to 79 degrees.

To find if there was any difference in the quickness of heating and cooling between living and dead parts, as also what difference, I made the following experiments.

I procured a dead and a living penis: the heat of the living penis, an inch and a half in, was 92 degrees. I heated the dead one to the same degree, then immersed both in water at 50 degrees. The dead one cooled fastest, but only two or three degrees; the living one coming down to 58 degrees, while the dead one came down to 55 degrees. I repeated the same experiment several times with the same result.

The standard heat of the human body

is about 99 degrees, and I believe that degree is pretty regular; however, this regularity in some degree arises from their being in every body a considerable mass of matter which causes less consumption of heat. This standard is necessary for the more material actions of life.

The heat of the more imperfect animals is not the same in every part of the body, even when there appears an equal mass of matter. To ascertain this, I took a healthy dormouse, the atmosphere being at 64 degrees. I put the thermometer into the belly, nearly in the middle between the thorax and the pelvis; it rose to 74 degrees; at the diaphragm it rose to 80 degrees, against the liver to 81½ degrees.

As there is some difference between the heat of an animal at the source of the circulation and that of the mouth, pelvis, and rectum, we must make an allowance in judging of the heat of the heart by that of these parts.

I next wanted to ascertain if cold applied to an animal would act as a stimulus, and therefore greater heat be produced than the common standard.

I took a healthy mouse,—atmosphere 64 degrees,—introduced the ball of the thermometer between the thorax and the pelvis. The mercury rose to 74½ degrees, at the liver to 81½ degrees. I put the mouse into an atmosphere at 30 degrees, and when the ball was again introduced into the belly the mercury rose to 92 degrees, at the liver 93 degrees, the animal being still very lively. Here was an increase of 17½ degrees in the belly, and 11½ at the liver, and this produced by the application of cold to the skin.

Of the Resistance to foreign Heat above the standard.—We have found that animals evidently possess a power within themselves of producing heat when in a cold atmosphere, so as to keep their bodies in a temperature suitable to the œconomy of the animal. But as animals are often placed in an atmosphere much hotter than their standard heat, I wanted next to see how far they have a cooling power, or, if they have not, to what degree the heat of an animal might be increased, and what might be the consequence of that increase, supposing it possible; for *a priori* we should suppose that the standard heat, or that heat at which all the animal functions are best carried on, would be the medium heat of the animal. But I find from experiment that the standard is generally within a degree or two of the ultimate

heat that the animal can bear. As allowing the heat to rise above the standard could answer no wise purpose, Nature has put a check to it by making the stimulus of heat the cause of its own annihilation, just as the stimulus of cold produces, on the other hand, an increase of heat.

This would appear to take place in two different ways: one is by evaporation, which arises from the action of the living powers; and the other by an immediate power of destroying heat. So that animals have two means of destroying heat, while it would appear that they have only one for the production of it.

I put a viper into an atmosphere at 108 degrees, and allowed it to stay in seven minutes, when the heat in the stomach and anus was $92\frac{1}{2}$ degrees, beyond which it could not rise in the above heat.

The same experiment was made on frogs with nearly the same success.

I now tried to what degree of heat I could bring a more perfect animal; and as I found the penis the best part for trying the experiment with cold, I imagined it would be the best for the trial of heat. The experiments were made in the same manner with the former, only the water was now hotter than the heat of the man. These were only simple experiments, but I chose to make a comparative one with a dead penis.

A living and dead penis were immersed in water gradually made warmer and warmer, from 100 degrees to 118 degrees, and continued in this heat for some minutes. The dead penis raised the thermometer to 114 degrees, while the living could not raise it more than 102 degrees. It was observed by the person on whom the experiment was made, that about a minute after the part was put in water the water did not feel hot, but on the water being agitated it felt so hot that he could hardly bear it. On applying the thermometer to the sides of the living glans, while in the water, the mercury fell from 118 degrees to about 104 degrees, while it did not fall above a degree when put close to the dead penis, so that the living glans produced a cold space of water about it. This experiment may may furnish a useful hint about bathing in water, whether colder or warmer than the heat of the body; for if it is intended to be colder or hotter, as it will soon be of the same temperature with that of the body, the patient, if in a large bath, should move from place to place, and in a warm

bath there should be a constant succession of water of the intended heat.

The experiments made by Dr. G. Fordyce in heated rooms prove, in the clearest manner, that the body has a power of destroying heat.

The action of evaporation produces cold, and in proportion to the quickness of the evaporation is the cold produced; and from experiment we find that the evaporation of spirits of wine produces cold faster than that of water, and of æther faster than spirits of wine. On this principle we suppose that evaporation is one means of producing cold in the living body.

It appears from Dr. Fordyce's experiments that the living powers were very much assisted in generating cold by evaporation, but that evaporation was not the sole agent in keeping the body cool. There is therefore a further provision of Nature for enabling animals to support great heat. In order to keep up a just balance of temperature, it is probable that the living powers exert greater effort as evaporation is deficient, and less effort as evaporation increases. In emergencies, evaporation is not sufficient: when a greater power of producing cold than ordinary is required, the powers of the animal are called forth.

As animals can only destroy a certain quantity of heat in a given time, so the time they can continue the full exertion of this destroying power seems also limited. It is probable that both the power of destroying heat, and the time in which that power can be exerted, may be increased by frequent exercise.

When Dr. Fordyce was in the heated room, his hand became so hot as to make his body feel cool to it. It is probable that that part, from its habit of changing its degree of heat, is more ready to take on different degrees of heat applied. It is found from experiment, in the application of cold, that all the extremities are more subject to the laws of inanimate matter than the body; and the nearer the source of circulation, the greater the deviation is from these laws. Possibly the same may be observed with regard to heat.

In animals which have a standard heat it would appear to be more natural to form than to destroy heat, (although the power of destroying it appears to be much greater than that of producing it,) for we may observe that they live with much more ease to themselves when in an atmosphere considerably lower than their

standard, in which they must constantly be generating heat, than in an atmosphere even of their own temperature, in which it cannot be necessary for them to form heat; so that either this action simply of generating heat, or being in such a degree of cold as makes this action necessary, proves salutary to the constitution. Perhaps the medium between their extreme heat, which is 98 degrees, and the lowest degree they can come to, is the proper and most wholesome temperature of the atmosphere, and this is about 63 degrees.

Some of these animals which are endowed with this property of a standard heat have this power of generating heat much stronger than others, and are always best in those situations where this power can be exercised: we should naturally suppose that this power always requires a necessity for that exertion equal to its power, so that the power and the necessity should always be proportioned. This cannot be the case with those imperfect animals which have little or no power of forming heat, but are obliged to the atmosphere for heat.

When we consider the white bear, the fox, and wolf, in the more northerly climates, inhabiting countries where the temperature is below zero, yet having a power of preserving their noses, feet, tails, &c., while man, with all his care and art, loses his extremities in the same degree of cold, we must acknowledge that those animals have by much the greater power of generating heat of the two. When we compare the above animals with the lion, tiger, monkey, &c., we find the proportion in the power of generating heat between these two classes of animals still greater; for if the human species finds it impossible to generate heat like the white bear, &c., the lion and tiger must find it impossible to generate heat equal to man: for though they may not lose parts of their bodies when in cold that is tolerable to the human species, they lose their lives in the end.

It may be desirable to inquire into the proper temperature for each of those classes above-mentioned, that is, the temperature in which they carry on their ultimate actions. This must be ascertained with great difficulty; perhaps the temperature suitable to the white bear, &c. is about 50 degrees; for the human species about 60 degrees; for the lion, tiger, &c. about 70 degrees; and there may be some which may require a still higher temperature, though probably none will require a lower than 50 degrees.

On the Effects of Climate.—By climate we mean that state of the atmosphere which is peculiar to any particular part. Climates vary as much as anything in nature. Their difference may be said to arise chiefly from the influence of the sun, from the moisture or dryness, which will depend partly on the shape of our globe and its oblique direction with regard to the sun, and also from the nature of the surface, whether hilly, or flat, or woody. The different seasons are dependent on the form of the earth and its motion round the sun. Between the tropics the variations of seasons are less; still there are kinds of seasons, and the climates are very various. The greatest variety of climate is near the tropics. The world there, being chiefly if not altogether heated by the sun, works very hard to gain as much of its influence as possible; it exposes itself to it as much as possible in every direction. The air of the equator is very different from that of the poles; few can live in the climate of the poles, either animals or vegetables, and even of those which can live many become torpid during the winter. It is wonderful, considering the necessity of heat to animalization and vegetation, and how partial Nature has been in the distribution of it, how both these processes go on so well as they do. Nature, however, has been obliged to adapt animals to their different climates as well as vegetables, except the bramble, which lives between the tropics and at the poles.

Some animals become torpid during the cold, others even of the same order do not; this seems to be because the food of the first is not to be found during that season: so nature formed them either animals of passage, as some birds; others she constituted so as to become torpid. Animals of passage, however, seem to have their peculiar climate; fish, which wander more than most animals, have their climate, and the general cause of their moving south is for the purpose of propagation. So herrings come from the North Pole to the coasts of Europe and America, for no other purpose than to lay their spawn. Quadrupeds seem the best formed for variations of climate, though their heat is more stationary. There are exceptions, as the dormouse, bat, &c.; but men, dogs, deer, horses, &c. live tolerably well, though not without disease, between the tropics and also far north. Nature has furnished some animals with mechanical means for adapting them to climate, as hair, feathers, &c.

The use of hair is clearly to preserve warmth: the porcupine of Italy has no hair, but only quills; and the southern bears have only bristles, without hair. There are some animals furnished with proper non-conductors of heat, as seals, sea-cows, &c., whose hair can be of little use to them while living in the sea, and is therefore only useful to them perhaps while on land. Those animals, as whales, which, from living constantly in water, could derive no advantage from hair, have an immense quantity of fat, which is a worse conductor of heat than water by nine to one.

REPORTS OF OBSTETRIC CASES IN PETERSHAM WARD.

By DR. ASHWELL.

(From Guy's Hospital Reports.)

Abortio.—The case of abortion was induced by the patient's attempting to lift a heavy weight. On her admission into the Hospital, she was suffering from all the symptoms from loss of blood. The sulphate of quinine, generous diet, porter, and rest in the recumbent posture, succeeded in restoring her system to its proper tone.

Amenorrhœa.—The cases of amenorrhœa were, in number, eighteen. Ten of them were cases of simple amenorrhœa: two occurred in patients of highly plethoric habits; and the remaining six were complicated with local affections. The cases of simple amenorrhœa were treated by aperients, metallic tonics, and emmenagogues. Injections of liq. ammoniæ and milk, in the proportion of m. x. of the former to ʒi. of the latter, were successfully employed in some cases; while several appear to have derived considerable benefit from electricity—a remedy frequently resorted to in the ward, during the last twelve months. In those cases where the healthy condition of the alimentary canal has been restored, and uterine torpor continues, slight electric shocks, passed through the loins, advantageously stimulate the genital system, and, occasionally, at once induce the catamenial secretion. Still electricity is uncertain; and it will often be employed unsuccessfully: in some instances, the alarm attendant on its use has cured the amenorrhœa, by suddenly exciting menstruation. The six cases of com-

plicated amenorrhœa were very interesting. In one, it was associated with chorea. This patient, after protracted treatment, was eventually cured by sulphate of zinc, and the injection of liq. ammoniæ into the vagina. In another, amenorrhœa was complicated with epilepsy. The medicine prescribed was ferri sulph. gr. i. pulv. digitalis gr. i. pulv. myrrhæ gr. ij. mucil. Acaciæ q. s. fiat pilula ter die sumenda. It is worthy of remark, that these pills were persevered in for three weeks, without any injurious consequences from the use of the digitalis; a circumstance attributable, probably, to its combination with the iron. At this period, the catamenia appeared; and there has been no return of the fits. In a third case, hemiplegia was attendant on the amenorrhœa. This complication was tedious, and difficult to manage. At first, the mist. ferri c. was prescribed; afterwards, the sulphate of zinc; and an iodine liniment was rubbed over the spine, night and morning. Menstruation was eventually established, and the patient gained the entire use of the side. In the fourth case, there was tænia with the amenorrhœa. In addition to the other remedies, the ol. terebinth. was curatively employed. In the fifth patient there was vicarious discharge from the mamma, in conjunction with amenorrhœa: the mist. ferri c. was ordered, as well as the daily employment of the ammoniacal injection. The last patient had, in addition to the amenorrhœa, a peculiar nervous affection of one of her lower extremities, which completely subsided when the catamenial function was, by appropriate remedies, healthily established.

Anæmia.—This patient was suffering from a considerable loss of blood after delivery, occasioned by a partial adhesion of the placenta to the uterus. Tonics, nutritious diet, and astringent injections, soon restored her to a state of convalescence.

Carcinoma Uteri.—*Carcinoma Uteri et Vaginæ*.—Six cases of carcinoma affecting the uterus alone, and two implicating both the uterus and vagina, have been admitted. The former consecutively presented the various indications of the disease, from the scirrhus hardness, to complete ulceration, with fungoid growth. In the two latter, the inguinal glands were enlarged and indurated. These distressing maladies were treated, by preventing, as far as possible, every cause of irritation; and by the cautious exhibition of anodynes, by the mouth, by injection, and as suppositories within the rectum.

Occasionally, considerable relief was afforded by a plaster of the extract of belladonna, applied over the sacrum and loins.

Chlorosis.—There have been eight instances of chlorosis, comprising both the simple and complicated forms of the disease. Purgatives, tonics, and emmenagogues have been the medicines employed; suiting their exhibition, combination, and dose, to the various cases.

Contractio Vaginæ.—This occurred in the person of a woman, aged 30, who had given birth to five still-born children. From some unknown cause, inflammation occurred in the posterior part of the vagina, followed by an abscess; in the healing of which, so great contraction occurred as materially to interfere with intercourse. A bougie was ordered to be applied daily; and she left the hospital considerably improved.

Climacteric Disease.—The two cases of climacteric disease occurred in persons above fifty years of age, and well portrayed all the symptoms so excellently described by Sir H. Hallford, in his essays: they had both contracted second marriages late in life, and had suffered, although in a very slight degree, from leucorrhæa. Astringent injections, the employment of stimulants with tonics, as the inf. serpentariæ, with the ammoniæ sesqui. carb., comprised the treatment.

Dysmenorrhæa.—This patient was twenty-two years of age; and had been affected with menstruation for four years, the pain recurring with great intensity about twenty-four hours before the accession of the catamenia, and ceasing as the flow increased. Hyoscyamus and camphor, with the hip-bath, were the remedies employed during the period; and the iodide of iron during the intervals of menstruation. She left the hospital well.

Fungoid Excrescence.—This woman, when admitted, was forty-seven years of age: she had twice miscarried, and had borne five living children; the birth of the first being followed by hæmorrhage, so excessive as to endanger her life. For two years before admission, she had had sanguineous discharge at intervals. On examination, a fungoid excrescence was found to protrude through the os uteri, probably growing from the lining membrane of the uterus: by the aid of the speculum, veins were seen to ramify over the tumor, which bled on the slightest exertion or emotion. Astringent anodyne injections into the vagina, to allay the pain and repress the hæmorrhage, with

anodynes and tonics, comprised the treatment. At her own desire, the patient was presented; the disease having all but destroyed her life. The plug of tow, dipped in alum water or tincture of galls, was strongly recommended.

Hydrops Ovarii.—Six cases of ovarian dropsy have been received for treatment. Of these, four were married, and two were unmarried women: in three, the diseased commenced on the right; and in three, on the left side. Two only were tapped, and both successfully: in one, the operation had been performed before. Their ages were as follow

Unmarried, 39 years, left side, stationary.

Married, 1 child, 38 years, left side, stationary.

Married, 1 child, 3 mis. 51 years, right side, tapped.

Married, 7 children, 45 years, left side, increasing.

Married, 1 child, 51 years, right side, tapped.

Unmarried, 30 years, right side, died.

Hysteria.—There has been but one case of an hysterico-epileptic nature; which required local bleeding, purgatives, and the subsequent employment of the mist. assafetida.

Imperforatio vaginæ.—Two cases of imperforatio vaginæ have been received for treatment. One, the instance of Elizabeth Rusher, is fully described hereafter. The other occurred in the person of a girl, aged 17. She had for nearly eight months complained of great pain in the loins, and other symptoms, which led to the suspicion of the mischief. On examination, the labia were found separated by a projecting tense body, resembling, in form and feeling, the membranes containing the liq. amnii during pain. An opening was made; and about two quarts of thick fluid escaped, having the appearance of melted emp. roborans. The vagina was injected with warm water; and, on examination, the os uteri was felt, high up, dilated to the size of a shilling, and the upper part of the canal was very capacious: a piece of lint was placed in the opening, and she shortly left the hospital, cured.

Induratio Oris Cervicisque Uteri.—Leucorrhæal discharge, with more or less of central pain, marked the whole of these cases. In three, the anterior limbus of the os uteri was indurated, and micturition was painful and difficult. In the fourth case, the posterior limbus was affected; and there was pain and difficulty

in emptying the rectum. For treatment, reliance was chiefly placed on the internal administration and the external application of iodine.

Inflammatio Mammæ.—The three cases of mammary inflammation occurred in first confinements: before admission, abscess had taken place. Tonics, as the quinine, porter, &c., were administered, to support the patient's powers during the process of suppuration.

Inflammatio Oris Cervicisq; Uteri.—These cases were marked by the creamy discharge; pain in the erect position, greatly increased by examination, &c. Cupping on the loins, anodyne injections, mild laxatives, with hyoscyamus, and absolute rest in the recumbent posture, comprised the whole of the treatment.

Irritable Uterus.—In these three cases, there were the usual symptoms; pain in the lower part of the abdomen, passing round to the loins, and running along the brim of the pelvis: relieved, but not removed, by the recumbent position. The hip-bath, hyoscyamus and camphor, assisted by the employment of anodyne injections and suppositories, mitigated the pain; while tonics, as the calumba, cascarilla, and quinine, were administered, to maintain the powers of the constitution.

Leucorrhœa.—Five cases of leucorrhœa were received for treatment: in all, the discharge was very profuse, and had continued so long as to produce many of the symptoms of loss of blood; as, pallor of the surface, œdema, dyspnœa, &c. The treatment consisted in enjoining the strict and periodical employment of astringent injections; as, the lot. alum. c., the lot. arg. nit., or the lot. ferri sulph. In administering tonics, both mineral and vegetable; of the former, the sulphate of zinc and the mist. ferri comp. were preferred; of the latter, gentian, calumba, cascarilla, and quinine.

Menorrhagia.—Two of these cases may be stated as active, and the three as passive menorrhagia. To the former, there were all the attendant marks of plethora; as, fulness about the pelvis, heat and throbbing of the genitals, full pulse, tumid and painful mammæ: these were treated by cupping from the loins, saline purgatives, and refrigerants. The three cases of passive menorrhagia occurred in married women, who had had profuse leucorrhœa for some considerable time. Great benefit was derived from the employment of the ergot of rye, both internally, and externally, in the form of injections.

Polypus Uteri.—Two cases of polypus uteri have been received for treatment. The first, in a woman, aged 47, who had borne nine children, and had once miscarried. Twelve months before admission, she was suddenly seized with a gush of blood from the uterus. These bleedings occurred, at intervals, up to the period of her admission: between the bleedings, she was never free from an aqueous discharge. On admission, the polypus was found to protude through the external parts. Ten days after her admission, it was tied, by means of the double canula. Three days afterwards, the polypus came away, and she did well.

In the second case, the patient was forty years of age, was married at 31, and was delivered of a still-born seven months' child, ten months afterwards. On examination, the polypus was found to have firmly adhered to the roof of the vagina; indeed so firmly, that it was utterly impossible to separate the adhesion, or to allow of the passing a ligature around the tumor; nothing, therefore, was attempted, as a radical cure.

Procidentia Uteri.—In three of the cases of procidentia uteri, the os was superficially ulcerated to some considerable extent; the inverted vagina appearing to have lost the character of mucous membrane, partaking more of the nature of common integument, and being of a pinkish colour. The black wash, with mucilage and opium, was applied, to heal the ulcerations. Afterwards, the parts were returned, and kept in situ, by a pessary.

Prolapsus Uteri.—Here the constitutional symptoms were far more severe than in the cases of procidentia, although in the three cases of the latter there was ulceration. Astringent injections, the lot. alum. c., lot. arg. nit., lot. ferri sulph. were employed, to excite the contraction of the vagina. Pessaries of various kinds were adapted to the several cases.

Prolapsus Vesicæ.—This displacement was occasioned by the patients' assuming the erect position too soon after a very difficult labour. There was great irritability of the vagina, with leucorrhœa. The only astringent injection that could be borne was the lot. arg. nit.; and the only artificial support, a piece of sponge.

Puerperal Convulsions.—Two cases of puerperal convulsions were admitted, both occurring during labour; one, in a patient completely anæmiated from poverty and starvation; the other, in a remarkably stout plethoric Irishwoman,

19 years of age, and unmarried. The former was treated with stimulants, tonics, nutritious diet, and evaporating lotions to the head; while in the latter case, the strictest antiphlogistic remedies were employed. Both cases terminated successfully.

Tumor Abdominis.—This patient, on her admission into the hospital, was reported to have “an abdominal tumor attached to the uterus, probably malignant.” By minute and careful examination, it was found to be external to the abdominal cavity, but posterior to the abdominal muscles. After some time, fluctuation became distinct; and she was transferred to the care of the surgeon, who opened the swelling, and gave exit to a large quantity of pus.

Tumor Meatus Urinarii.—One case was admitted, in which, growing from the orifice of the meatus urinarius, there was a small vascular tumor, giving rise to great pain in micturition, and bleeding on the slightest touch: nitrate of silver, daily applied, effected its removal.

Tumor Ovarii.—Two of these cases occurred on the left, and two on the right side. Three of the patients were single women; and the fourth, although married, was separated from her husband. The iodine ointment, applied externally, and the internal exhibition of the julep. iodinii c., was the treatment employed. If any unpleasant symptoms were occasioned, as vertigo, heat in the throat, or fulness in the epigastrium, the patient was ordered to take the carbonate of magnesia; and, temporarily, to discontinue the medicine. Although these measures were not successful in removing the disease, still they seemed to render it stationary.

Tumor Uteri.—This patient was forty-one years of age, unmarried, and had generally menstruated regularly. There was a hard tumor above the pubes, extending upwards to the right side, as high as the umbilicus. Internal examination detected it, growing from the fundus. At the time of menstruation the tumor became larger and painful. She was ordered to apply iodine ointment, and to take the julep. iodinii c. three times a day. She persevered for weeks, although without diminishing the uterine tumor; still, to the very great improvement of her constitutional powers.

Vesico-Vaginal Fistula.—Two cases have been admitted; both the result of protracted labours, in which perforation was resorted to. In one, the aperture admitted the joint of the fore-finger; in

the other, the opening was smaller; and the patient was benefited by allowing a catheter to remain in the bladder, as well as by the daily use of the injection of the liquor calcis and opium.

THE ANATOMIST.

THE THORAX AND ITS CONTENTS.

The thorax is bounded anteriorly by the sternum and cartilages of the ribs, posteriorly by the vertebræ and lesser circle of the ribs, and on either side by the shafts of the ribs and the intercostal muscles. Its upper orifice is transversely oval, and allows the exit and entrance of vessels, nerves, and muscles to and from its cavity; its inferior orifice, or circumference, being much larger, and closed by the diaphragm.

The thorax contains the heart and lungs, and also several vessels, nerves, glands, &c., to be noticed as we proceed.

THE PLEURÆ

Are two serous membranes, one on either side, which cover the inner surface of the thorax, and are reflected upon the outer surfaces of the parts contained in its cavity. That portion of the pleura which lines the thorax, is called the *parietal* layer, and that which lines the contained parts the *visceral layer*. Each pleura can be traced in the following manner:—From the posterior surface of the sternum it passes backwards until it meets with the anterior surface of the pericardium, along the side of which it passes to the anterior surface of the root of the lung; from this it passes upon the lung, and is reflected over the entire surface of the organ, until it arrives at the posterior surface of its root and of the pericardium, from whence it passes upon the sides of the bodies of the vertebræ, reaching as high as the transverse process of the sixth cervical vertebra, on the right side of the seventh on the left, and descending to the diaphragm, the thoracic aspect of which it covers; it finally lines the ribs and intercostal muscles, until it arrives at the portion which was opened, and which corresponds to the posterior process of the sternum.

Ligamentum latum pulmonis (one on either side) is merely a triangular fold of pleura, formed by the reflection of the membrane from the lower edge of the root of the lung upon the diaphragm.

ANTERIOR MEDIASTINUM.

A triangular cavity formed by tearing through the cellular tissue, which connects the right and left pleura behind the sternum; the base is formed by the sternum, the sides by the separated pleura and the apex corresponds to the anterior surface of the pericardium, where the pleuræ separate to enclose this bag. Thus formed, it contains the origins of the sterno-hyoid and sterno-thyroid muscles, branches of the descendens noni nerve, the remains of the thymus gland, lymphatic glands and absorbents, the mammary vessels, the triangulares sterni muscles and loose cellular tissue.

MIDDLE MEDIASTINUM

Is of an oval shape, and is formed by the reflection of the pleuræ upon the sides of the pericardium; it consequently contains this bag and its contents.

POSTERIOR MEDIASTINUM

Is formed by the reflection of the pleuræ upon the sides of the bodies of the vertebræ; it is of a triangular form, the apex anterior corresponding to the posterior surface of the pericardium, the sides formed by the pleuræ, and the base represented by the anterior surfaces of the bodies of the vertebræ; it extends from the third to the tenth dorsal vertebra, and contains the following parts:—the bifurcation of the trachea, the œsophagus and pneumo-gastric nerves, the thoracic duct, the vena azygos, the thoracic aorta, the splanchnic nerves, lymphatic glands, absorbents and loose cellular tissue.

THE LUNGS

Are two soft, spongy, vascular bodies, one contained on each side of the cavity of the chest. Each lung resembles a cone, with that side corresponding to the median line truncated; the base concave corresponds to the diaphragm, the obtuse rounded apex rises in the neck, a little above the level of the first rib; the extreme convex surface corresponds to the internal concave surface of the thoracic parietes, and the flat or truncated surface corresponds to the mediastina. The posterior edge of the lung is thick and rounded, whilst the anterior is thin and irregular. Each lung is distinguished into lobes, which are separated from each other by fissures; a little above the centre of each is the root formed by the pulmonary vessels and bronchial tube, connected to each other by cellular tissue,

and invested by the pleura. The bronchial tube is situated posterior and superior to the pulmonary vessels; the two pulmonary veins are placed anterior and inferior to the artery and bronchus, and the pulmonary artery is placed between the bronchus and the pulmonary veins, but behind the pulmonary veins and before the bronchus. The root of each lung has anterior to it the phrenic nerve and filaments of the pneumo-gastric nerve, posterior to it the pulmonic plexus, and in inferior the ligamentum latum. The root of the right lung has the vena azygos arching over it.

The right and left lungs differ from each other in some important particulars: the right lung is broader and shorter than the left, and consists of three lobes, separated by one fissure; the right also ascends higher in the neck, and the anterior edge of the left presents a notch where it corresponds to the apex of the heart.

The intimate structure of the lungs consists of the ultimate ramifications of the bronchial tubes, which are the continuations of the trachea, and the branches of the pulmonary artery and veins; they also receive bronchial arteries for their nutrition.

TRACHEA AND ITS RAMIFICATIONS.

The wind-pipe, or trachea, is a cylindrical tube, extending from the cricoid cartilage of the larynx to the level of the third dorsal vertebra. It consists of from seventeen to twenty fibro-cartilaginous rings, truncated behind, and connected to each other by an elastic membrane; about the posterior fourth of each ring is deficient, and it place is supplied by fibrous membrane.

Opposite the third dorsal vertebra the trachea divides into the right and left bronchial tubes; the right bronchus is larger than the left, and runs transversely into the root of the lung and divides into three branches; the left bronchus passes through the arch of the aorta to the root of the left lung and divides into two branches.

The bronchi consist of cartilaginous rings, but as these tubes advance into the substance of the lung they diminish in size and firmness, until their place is supplied by fibrous tissue, or transverse circular fibres, which tissue also disappears, and length nothing remains but the mucous membrane, which terminates in the air-cells, upon which ramify the ultimate ramifications of the pulmonary artery and

the commencing radicles of the pulmonary veins.

The ramifications of the pulmonary artery communicate with those of the pulmonary veins, beneath the mucous membrane of the air-cells, and are enveloped in fine cellular tissue; and except this cellular tissue the lung has no proper parenchyma, its structure being entirely filaments-vascular. The lungs are supplied with blood by the *bronchial arteries*, derived from the thoracic aorta; these vessels run along the bronchial tubes, subdivide as they proceed, and form a minute net-work on the attached surface of the bronchial mucous membrane; the blood they convey to the lungs is returned to the vena azygos, or superior cava. The nerves distributed to the lungs are derived from the eighth pair, and a few filaments from the sympathetic.

HEART AND PERICARDIUM.

The *pericardium* consists of two layers, an outer, or proper fibrous layer, and an internal, or serous layer. It is of a conical form, the base below connected to the central division of the cordiform tendon of the diaphragm; the apex above corresponding to the great vessels at the base of the heart, along the out coats of which the fibrous layer is gradually lost; it is connected laterally to the pleura and to the pulmonary vessels, and the phrenic nerves, one on either side, run in close contact with it to the diaphragm. Upon laying upon the pericardium, the cavity of the serous layer is exposed, and, like all serous membranes, consists of two portions—a parietal layer, which lines the inner surface of the fibrous pericardium, and a visceral layer which lines the outer surfaces of the heart and great vessels. Covered by the serous membrane, when the pericardium is fully opened, we bring into view the right auricle, the venæ cavæ, the left auricular appendix, the right ventricle, the tip of the left ventricle, which forms the apex of the heart, the aorta, the pulmonary artery and the anterior branches of the coronary vessels, with the ramifications of the cardiac nerves. Upon turning up the heart its posterior surface will be brought into view, presenting the left auricle, proceeding to which, on either side, are the pulmonary veins, and the left ventricle.

The serous membrane may be traced in the following manner:—after having lined the fibrous pericardium it is reflected on the superior cava, the aorta and the

aorta, and the pulmonary artery as these vessels are passing through the fibrous membrane, ascending highest, however, upon the aorta; inferiorly it is partly reflected around the inferior cava, as this vessel pierces the fibrous pericardium to enter the right ventricle, and laterally it is reflected upon the pulmonary veins as these vessels pierce the fibrous pericardium to enter the left auricle; from these different points it reaches the surface of the heart which it completely covers.

The *heart*, of a conical shape, is situate obliquely between the lungs, its base being superior, posterior, and to the right side its apex pointing towards the cartilage of the sixth rib of the left side. The axis of the heart is obliquely from right to left, and from behind forwards. It is retained in its situation by the great vessels and the reflections by the serous membrane.

The heart consists of four cavities, two auricles and two ventricles; the auricles are separated from each other by a partition, called *septum auricularum*, the ventricles by the *septum ventriculorum*. We shall examine these cavities in the order of the circulation.

The *right auricle* is placed between the two venæ cavæ, the blood conveyed by which it receives and transmits to the right ventricle; the small loose portion is called the *auricular appendix*, and the portion between the cavæ the *sinus of the auricle*. Upon laying open this auricle, by a perpendicular cut from the superior cava to within a few lines of the entrance of the inferior cava, and by a second cut from the centre of this, at right angles towards the auricular appendix, the following parts present themselves.

PATHOLOGY OF ECCHYMOSIS.

Ecchymosis literally means an effusion or escape of blood external to its vessels—"cruris in vicina spatia ob vasorum apertionem effusio." Ecchymosis is defined, an effusion or extravasation of blood from the capillary vessels, which are lacerated or broken, into the subcutaneous cellular tissue, and into the tissue of different vicinal organs.

It may be spontaneous, or produced by external injuries, as contusions, falls, blows, wounds, &c.

Spontaneous ecchymosis is extremely rare, and its reality is very much doubt-

though attested by some eminent writers of this century. M. Baumes describes an ecchymosed tumour, which was not caused by any external violence, (*Traité Elementaire de Nosologie*, T. 1, p. 322, 8vo. Paris, 1806.); and M. Rullier expresses much satisfaction in being able to attest this fact, as he had occasion to see several ecchymoses of this kind, which supervened without any appreciable external causes, on the hands and arms of two women, who otherwise enjoyed the best health. (*Rullier Dict. des Sciences Med. Art. Ecchymose*, T. 11, p. 112, Paris, 1814.) M. Rieux informs us that it is not uncommon to see persons go to bed in apparent good health, and rise next morning with an ecchymosis, or red spot, on the eye-lid. It does not follow that what this writer chooses to term ecchymosis is really ecchymosis, as defined by medico-legal writers. (*Theses de la Faculté de Médecine, de Paris*, 1814, No. 63.) There is also a dark colour round the eyes of some women during menstruation, which remains to be proved to be acknowledged ecchymosis; and there are individuals whose skin is so delicate and sensitive, that the slightest external causes will produce a well-marked black discoloration—but this may not be true ecchymosis. It is important to observe that spontaneous ecchymosis is doubted by the majority of the medical profession, and that the imperfect accounts now quoted are unsatisfactory, as they do not state whether the usual changes of colour, which occur in ecchymosis from injury, were really observed, and it is to be borne in mind that there could not have been an anatomical examination of the cellular tissue during life.

Contusions or bruises, which are synonymous, are always followed by solutions of continuity of capillary vessels, and sometimes of larger arteries or veins, and by extravasation of blood into areolæ or spaces of the cellular tissue, or into the tissue of different organs.

The effect of a severe blow, on the skin during life, is a bruise, or a laceration of capillary vessels, or a disorganization of these or of the areolæ of the cellular subcutaneous tissue, and more or less extravasation of blood which, in the living body, generally coagulates to a greater or less extent, after an indefinite period of time.

The ecchymosis has also been applied to false aneurism, thrombus, to certain diseases accompanied by black or dark

spots on the skin, and hence the term scorbutic, hæmorrhagic, ecchymosis, petechiæ, vibices, &c., but modern pathologists generally confine it to the blackness produced on the surface and deep-seated organs by external injuries; though some extend it to the appearance of organs after disease, not caused by external injuries.

Ecchymosis is generally said to be situated in the subcutaneous cellular tissue, but it is sometimes observed in the interstices between the muscles under the periosteum, in the serous membrane which covers the viscera, in the cellulous layer which accompanies the nerves and blood-vessels, and in the tissue of the different organs. The petechiæ, and vibices which appear in typhus, plague, pestilential diseases, blue cholera, small-pox, purpura hæmorrhagica, and scurvy, are termed ecchymosis by some writers. Thus Rullier maintains, that the morbid exaltation of the organic sensibility of the exhalent vessels of the subcutaneous cellular tissue and of the different organs is sufficient to retain the blood in these vessels, and to form ecchymosis without extravasation—which probably occurs in spontaneous ecchymosis, or in slight external causes which are incapable of rupturing the sanguineous capillary vessels. (op. cit. 117.) This spontaneous ecchymosis is termed sugillation by most modern medico-legal writers, and is caused, according to Van Swieten, by the impulsion of the blood in the small vessels (exhalents) which are affected differently from their normal condition, by admitting red blood, though they are unbroken, "Sanguis ingreditur vasa aliena, integra tamen." (Comment. in Boheraav. Oph. 324.)

In the petechiæ, vibices, and according to Rullier, in slight ecchymosis, in the advanced stages of typhous, low fever, pestilential diseases, and scurvy, the spots are caused by atony, or general relaxation of the organs, and especially of feebleness of the exhalent capillary vessels. These are incapable of resisting the blood, which is now attenuated and somewhat decomposed, and which escapes passively, and is effused by a kind of expression or transudation into the subcutaneous cellular tissue, or the viscera, and even into the tissue of muscles, as is frequently observed in the body of those who die of scurvy. It should be remembered that the blood thus effused does not coagulate in the above named diseases, and it is not clearly stated by authors whether the colorations remarked in ecchymosis from

external injuries occurs in the spontaneous species of the disease.

In ecchymosis from external injuries occurring during life, the spot is at first more or less red, bluish, and finally livid, or blackish, bluish, or leaden coloured; it gradually changes, becoming violet, yellow or citron colour, and it finally disappears in most cases. While undergoing these changes, the ecchymosis extends and enlarges by degrees; its circumference is less marked than its centre or the point first affected. The causes of this series of phenomena are in the state of the blood and cellular tissue, in fact, when the blood ceases to be submitted to the circulatory action, it loses by repose its vivid red colour, and becomes brownish, and tends to coagulate; but as there is a constant vapourous secretion in the areolæ of the cellular tissue, its molecules are successively diluted, and then dispersed by degrees by the tonic action of the tissue into the surrounding areolæ, and are finally removed by absorption.

When subcutaneous ecchymosis becomes painful, inflamed, and opens spontaneously, it discharges a fluid somewhat similar in appearance to lees of wine, which is an altered state of the blood.

It is also known to every observant practitioner, that ecchymosis caused by external injury may not occur immediately after the violence, or for some hours or days afterwards; for example, for ten or fifteen days, and that the muscles and deep seated organs may be ecchymosed, though the skin remains natural.

Diagnosis between Ecchymosis and Cadaverous Lividity.

Cadaverous lividity, livor (or suggillation, properly so termed by modern medico-legal authorities) occurs in the most dependant parts of the body. It is caused by congestion of the blood in the capillary vessels, which are distended; they often lose their vitality, but there is never any effusion or extravasation of blood in the areolæ of the subcutaneous cellular tissue. On incising the skin, the dark or brown colour found on its surface does not extend to the subjacent parts.

Cadaverous lividity generally commences some hours after death, when the body begins to cool, its members becoming stiff express the blood, which is still fluid, into the capillary vessels, but in some cases lividity commences before death has taken place or is real. Thus during the agony of various diseases, the

nails, hands, feet, the nose, lips, lobes of the ears, or the whole surface of the body, as in blue cholera, acquires a livid or violaceous tint, while in other cases the lividity does not occur for three or four days after death. This phenomena is chiefly observed when the blood has lost its consistence, when it is accumulated in the right auricle of the heart and trunks of the venæ cavæ, and when the abdomen is distended with gas. Under such circumstances, and according to the anatomical disposition of parts, the blood contained in the right auricle and venæ cavæ is forced into the veins of the neck and head, the vessels of the brain become engorged, the face acquires a marked tint, the eyes which were flattened and depressed fill and brighten, the pupil contracts, and the nasal membrane ruptures in some cases, and gives origin to a discharge of brownish blood from the nostrils. All vascular organs may become congested in the same manner. As the lungs for example.

In the last case the reason is obvious. All the blood of the body is returned to the lungs for the purpose of being oxidized or arterialized during respiration, but when the vital powers are greatly diminished, the last efforts of the heart fill the vessels of the lungs, distend and engorge them, giving a livid tint, more or less marked and extended, sometimes approaching to black, while the weight and density of the lungs are increased. The dark colour of the lungs has been mistaken for gangrene, but on cutting and washing the part with water the blackness disappears. The coloration is not equally intense on all parts of the lungs, and differs according to the position of the body while cooling after death. Thus, if the individual expires on the back, which is the most common position, the livid colour of the lung will be observed on the dorsal portion, if on the side or face, the lividity will be lateral, or on the anterior surface of the lung or body.

We also distinguish cadaverous lividity from ecchymosis as the former seldom occurs until some hours after death, occupies the most dependent, or lowest part of the body on account of the gravitation of the blood, and is caused by distention and not by rupture of the capillary vessels of the skin. It is only necessary to incise the livid parts to show that their tissue is normal or sound. In fine, cadaverous lividities disappear in a few hours, when the body is placed in an opposite position to that in which they occurred.

In an indefinite period after death the blood becomes soft, gelatinous, or like jelly, and it has been found to form concretions somewhat analogous to the buffy coat observed when blood is drawn in inflammatory diseases and during pregnancy. These concretions are very seldom found, and are usually seen in the heart and large vessels, and are generally considered to occur during the agony of death. Simulating lividities are attempted by rubbing certain parts with antimony, lead, &c., but these are readily detected.

Contusions inflicted on the Body after Death.

Persons have inflicted blows and injuries on the body after death to gratify their barbarous propensities, or for the purpose of accusing an innocent person of murder. It is, however, easy to distinguish between contusions and wounds inflicted during life, before life has entirely ceased, and after real death has occurred. When injuries are inflicted while the body is still warm, the blood fluid, and the muscles capable of contraction, the appearances will slightly resemble those inflicted during life. But in this case there will be no tumefaction on the edges of a wound, the blood which escapes from the extremities of the divided vessels does not form a solid clot, nor does it adhere to the surface of the wound, and there is no extravasation of blood produced in the areolæ of the cellular tissue.

But when the contusions are inflicted after the body is cold, the members rigid, the blood arrested in its vessels having lost its fluidity, the lips of a wound will be pale, placid, and not swollen or separated from each other, as when inflicted during life. All this shows that life had ceased, and that there was no reaction after the injuries.

If a dead body be thrown from a height to the ground, or other violence applied, the bones may be fractured, and the liver, spleen, brain, and other organs ruptured. But in such cases there will be no engorgement or extravasation of blood in the adjacent tissues.

It is also important not to confound black spots, which appear when the body is in an advanced state of decomposition, with ecchymosis, but these can be readily distinguished by the fetidity and other appearances of the body.

An incised wound was made in the calf of a leg, *two minutes* after its separation from the body by amputation, and the gastro-cnemii muscles were divided.

At the moment the wound was made, the skin retracted considerably, causing a protrusion of adipose substance, which only allowed the escape of a small quantity of blood. In twenty-four hours the edges of the wound were red, bloody, and everted; the skin was not in the least degree tumefied, but flacid. On separating the edges, a small quantity of fluid blood escaped, but no coagula adhered to the muscles. There was, however, at the bottom of the wound, a small quantity of coagulated blood, but the coagula were so loose as readily to break down under the finger.

In a second experiment, made *ten minutes* after the separation of the limb, the skin had lost its elasticity, the edges of the wound were very slightly everted, and scarcely any blood escaped from it. On examining the wound after the lapse of twenty-four hours, the edges of the incision were pale and perfectly collapsed, presenting none of the characters of a wound inflicted during life. There were some slight coagula at the bottom of the wound. It was found, by other experiments, that the longer the wound was deferred after death, the less were the appearances like those of a similar injury inflicted during life. Thus, when the wound was not made for two or three hours after the limb was removed from the body, although a small quantity of blood was effused, no coagula were found. The edges of an incised wound made twenty-four hours after death, are yielding elastic, in close approximation, and free from any coagula of blood. Such are the conclusions of some of our medical jurists, and they accord with those of almost all modern medico-legal authors.

It is to be recollected, that contusions or wounds, are most likely to be inflicted, as in Greenacre's case, immediately after apparent death, that is, before real death, in the strict physiological sense, has taken place.

HYPERANTHERA MORINGA.—The root of this tree is said to possess all the stimulating properties of the horseradish; it is used in the treatment of those cases of beriberi, which are attended with low action and debility; it diffuses warmth over the abdomen, and appears to encourage a warm perspiration; and, in the flatulent distention of the abdomen in confirmed cases, is a grateful tonic.—*Malcolmson on Beriberi.*

The London Medical

AND

Surgical Journal.*Saturday, July 1st, 1837.***DEATH OF HIS LATE MAJESTY.***(From our Windsor Correspondent.)*

Our readers will have perceived that we gave the only correct information which appeared on the hopeless nature of the late King's disease, which was borne out by his demise, and is still further corroborated by the autopsy which we subjoin. Our animadversions on the concocted bulletins were loudly demanded, and leave no doubt in the public mind, that no reliance whatever is to be placed on such documents. It will be obvious to our readers, on perusing the real and fatal diseases of the revered monarch, there could not be the slightest hope entertained of his recovery; and yet the bulletin-makers assured the public that he was able to transact the kingly offices to the very hour of dissolution. The case is also replete with instruction, for it was announced, that great benefit was derived from the use of the inefficient medicine called *senega*—in organic disease of the heart, effusion into the chest, and disorganization of the kidney. This is a salutary lesson to ordinary practitioners, who generally maintain that such degenerences in an aged subject are generally incurable. The following evidence proves the correctness of their conclusion :

POST MORTEM EXAMINATION OF HIS LATE MAJESTY.

On examining the mortal remains of his late Majesty William the Fourth, the following appearances were noticed :—

In the right cavity of the chest there

was an effusion of about fourteen ounces of serous fluid.

The lung on that side was nowhere adherent, the vessels of the lower lobe were very much tinged with blood, and the air-cells contained a mucous and serous fluid having a bloody tinge.

The left lung adhered generally and with great firmness to the surface of the pleura lining the chest; these adhesions appear to have resulted from former attacks of inflammation.

The vessels of this lung were also tinged with blood, and its lower portion was somewhat indurated.

The rings of the trachea and bronchi were ossified to a great extent; and the lining membrane was of a dark colour, in consequence of the distended state of the vessels.

The pericardium adhered universally to the surface of the heart; but these adhesions were slight, and appeared to be of very recent formation.

The heart itself was large, and softened in its texture. Its right side was extremely distended with blood, but exhibited no marks of organic disease.

On the left side of the heart the mitral valves were found to be ossified, and the three semilunar valves of the aorta were in the same state. The ossification was in two of them to such an extent, that it must have materially interfered with their functions.

The coats of the aorta were much thickened, and on its inner or lining membrane there were several deposits of earthy matter.

The liver was somewhat enlarged and hardened, and was of a granulated structure throughout.

The gall bladder was extremely contracted, and contained but little bile.

The spleen was increased to double its natural size, and a large portion of its

surface was covered with a cartilaginous deposit.

The pancreas was enlarged and indurated.

The stomach and intestines were healthy, except at one part of the large intestine, which was narrowed by a thickening of its inner membrane.

The right kidney was quite sound, but the left was unusually vascular, and exhibited a granulated appearance. The investing membrane adhered very slightly to it.

The bladder was in a healthy state.

ROYAL COLLEGE OF SURGEONS.

Conclusion of Professor Owen's Lectures on Comparative Anatomy.

On Tuesday last Mr. Owen concluded his short, but highly interesting and instructive course of lectures on Comparative Anatomy. The theatre of the College was somewhat more than half full; and we wonder the more at this, in consequence of it being generally understood that the learned professor intended to conclude his labours, by a brief allusion to the origin of the foundation of the professorship, and the benefits which the body of the profession at large were likely to receive from the new and *apparently* liberal proceedings of the council.

Sir Astley was, as usual, at his post; on this occasion he was supported by Sir Anthony Carlisle, Mr. Viucent, and Mr. Stanley, who were the only members of the council present. We do not recollect

"even in our boyhood days" to have seen the worthy Baronet in apparently better health or spirits: not a single observation of the lecturer seemed to escape him; he was all energy; the preparations in illustration of the lecture passed rapidly from the hands of Mr. Owen to those of Sir Astley; and so much did the latter identify himself with the subject, that upon several occasions he actually proceeded to demonstrate the preparations to those around him, to the no little confusion of Mr. Owen.

The subject of the lecture was the Comparative Anatomy of the Teeth, and we only regret that the absurd and foolish regulations of the few self-elected individuals who have taken upon themselves the management of the affairs of the College, should have cramped Mr. Owen as to time, and thus have deprived the members of the only return ever offered them in the shape of compensation for the money they have contributed, not only to the erection of the new building, the support of the museum, library, and those deserving individuals under whose management both these departments are placed, but also to the support of the *ignobile pecus* who form the court of examiners, and who coolly pocket a *third* of the diploma fee for THEIR SERVICES!

The truly rapid sketch which Mr. Owen took of the developement and classification of the teeth in the various classes of animals, was necessarily most imperfect. The idea of giving even a faint outline of these organs in the various groups of animated nature "in one short hour," is too absurd to require comment; to do justice to their investigation in the *human subject* took a quarto volume from the pen of Hunter, and occupied many an hour of that great man's valuable time; and knowing this we wonder that Mr. Owen would have submitted his judg-

ment to any regulation as to limitation of time which the *enlightened* council might have imposed upon him. Feeling the awkward situation in which he was placed, the learned professor had to draw upon the patience of his audience a half hour beyond the time allotted to the lecture; when, evidently finding the absurdity of attempting to proceed in the subject further, with advantage to himself or his hearers, he terminated abruptly, contenting himself with enumerating the difference in the number of teeth in the child and in the adult. Mr. Owen in a neat address, then complimented the worthy baronet on the many contributions which he had given, from time to time, to the Sciences of Anatomy and Physiology, and held Sir Astley Cooper forth as an example for all those to follow who were engaged in the arduous pursuits of our profession, and who felt desirous to arrive at any eminence in it. "The name of Cooper," said Mr. Owen, "will live for ages. Your discoveries, Sir, (addressing the worthy Bart.) and unwearied exertions in the practical part of your profession, have already reached the four quarters of the globe. You are as well known abroad as you are within these walls. And I cannot allow this opportunity to pass, sir, without returning you my heartfelt thanks for the intense interest you have taken in my humble endeavours to elucidate the opinions of your great predecessor, John Hunter."

That Mr. Owen did not here conclude with this just eulogium on the merits of Sir Astley Cooper we regret; for much as Mr. Owen may feel personally towards the individual members of the council, in making the professorship, and appointing him to perform its duties, it makes very little matter to the body of the profession at large, so long as the professorship is ably filled, and is likely to be of public

utility. We are sorry then that Mr. Owen did not remain silent on this head; to say the least of it, it was very bad taste; particularly as there have been, within the last year, certain proceedings upon the part of the council, collectively and individually, which call for immediate attention; and of which it shall be our duty, in a short time, to take notice.

NON CONGENITAL HYDROCEPHALUS.

Resolutive treatment.—Practical Reflections.

Hôpital dit de l'Ecole.—CLOQUET.

An infant eight months old, weak constitution, was in good health till he was five months old; at this period he was seized with violent convulsions.

A meningitis was suspected, and the child was treated accordingly. Leeches behind the ears; cold water applied to the head, sinapisms to the feet; great relief. The child became dull, morose, and fell into a lethargic state; great agitation during sleep, sudden starts at waking, and convulsions came on occasionally. The size of the head increased remarkably. The parents took it to the hospital, and the following symptoms now exist.

Head very large; separation of the bones of the skull; the forehead very prominent; depression of the angle formed by the occipito-frontalis lamina; distention and thinness of the skin covering the sutures; transparency of the fontanelle; pressure on these parts causing remarkable fluctuation, great diminution of the ocular and auditory faculties, general weakness in all the limbs; the head unable to bear its own weight, falls on the shoulders, or on the chest.

With these symptoms it was easy to ascertain the existence of hydrocephalus; application of two large blisters on the head, calomel to be taken internally. This treatment was commenced only within two days; later on we shall give its results.

The manner in which this case of hydrocephalus first shewed itself is worthy of notice. Convulsions in the first instance, but on what did these convulsions depend? Where they caused by arach-

nitis, as was originally supposed? This would be very difficult to decide. We are certain that convulsions often form part of the symptomatology of hydrocephalus, so that in this case the effect might have been mistaken for the cause. Boyer was of opinion that hydrocephalus was manifested shortly after birth. This state may have commenced during the intra-uterine life, so that it might be considered as congenital; such perhaps has been the case we have here related.

Revulsive medication, by the aid of blisters and calomel, may be very useful, as examples of cure by this method have been given, but the disease must not have made such progress as in the case here stated. The cephalic paracentesis in cases of hydrocephalus, has not been renewed since the fatal experiments made by Lecat.

Having observed that the patients generally died when the *poche* was opened, either spontaneously, or by the hand of the surgeon, this operation has been quite given up in France. Boyer condemned, in the most decided terms, puncture for hydrocephalus, the same as he had done for hydrorachis; we have nevertheless seen a case of this last disease cured by several punctures made with a very small needle, so as to prevent the entrance of air in the *poche aereuse*. Could not the same plain method be pursued for certain varieties of hydrocephalus? This is no longer doubtful, for those who are aware that Graefe succeeded once in three times in curing hydrocephalus, by the use of repeated puncture cephalocentesis. If Lecat failed in this operation, it is perhaps because his plan of leaving the canula permanently, is very defective.—*Continental and Brit. Med. Rev.*

SCIRRHOUS INDURATION OF THE NECK OF THE UTERUS.

Amputation.—Cure.

BY DR. CAZENAVE.

A lady had for ten years been troubled with an affection of the womb. A surgeon having erroneously attributed the symptoms to a syphilitic affection, prescribed mercury which induced several hæmatemesis, but had no advantageous effect on the womb. Other practitioners were called in, and found commencement of a disease of the neck of the womb, but

as the patient would not consent to a full examination, only a few palliatives were prescribed.

Later on, the speculum was applied, the *museau de tanche* had increased in size, was rather hard, rough, and painful. There was also on the neck of the womb an erosion, which soon disappeared. Various medications were recommended, though not regularly taken. Mr. Chomel was consulted, and ascertained the existence of a scirrhus tumour on the neck of the uterus; he advised immediate amputation, which was declined.

M. Cazenave being called in sometime afterwards, found this lady with a dark complexion, and the eyes dim: she complained of palpitation of the heart, and dumb pains in the uterus, which pains also extended to the thighs. She had severe colics, and pains in the lumbar region. There was slight effusion in the body of the uterus. This diagnostic being confirmed by the application of the speculum, it was decided that amputation of the neck of the uterus should take place.

A bivalve speculum was introduced, and the neck caught by Muzeux's long pincers, was gradually drawn outside the vulva. Other pincers were then used; but notwithstanding the repeated efforts, it was impossible to bring out the posterior lip, which was largely developed, and the incision was made in this position. The operation was difficult, but ended satisfactorily. The patient was put into bed, she fainted, but no further accident happened, and she recovered.

The separated tissues were evidently of a scirrhus nature; fibrous, cartilaginous, larger than a hen's egg, and weighed more than an ounce and a half.

We cannot too forcibly call the attention of practitioners to the necessity of using the speculum, as the best means of diagnostic in all affections of the womb. M. Cazenave's reflection on this subject are very judicious. He says diseases of the body and neck of the womb are extremely common in large towns, and make considerable havoc, as females unfortunately only seek medical advice when these affections are far advanced, or because they attach no importance to slight indispositions, which being symptoms of greater evil, should attract attention.

For the last twelve months I have attended females in all ranks of life, having engorgements, schirrus or cancer, sometimes confined to the neck of the womb, and sometimes invading both the neck and body. Some of these patients suf-

ferred very little, although degenerescence advanced rapidly; others felt acute pains when there existed only slight engorgements and superficial phlogosis, that very simple means, and particularly a horizontal position speedily removed. I have lately seen two ladies in whom a copious white discharge, pains in the stomach, hip, and thighs, thick and dark complexion, pains in the lumbar region, loss of strength, had scarcely attracted the attention of their medical advisers, who were nevertheless able men; but they only thought of one of the consequences—of the shadow of the evil; in short, of the white discharge; and were surprised that their irrational prescriptions did not produce a cure.

Suspecting the fact, I touched the neck of the uterus; in one patient I found a hard engorgement nearly scirrhus; and in the other, an ulceration as large in circumference as a sixpence. These mistakes are very common, and are productive of the most fatal results to the patient, injure the reputation of the practitioner, and very justly, as now we are furnished with the means of feeling and seeing the diseased parts, mistakes are inexcusable.

Since we have had so many enlightened men in the ranks of science, diseases of the uterus may be cured whenever the medical attendant will take sufficient pains to ascertain in time, the real state of the case, and however repulsive it may be to women's feelings to submit to an exploration by the finger or speculum, yet their own good sense will lead them to do so, if it be properly shewn that such a step is indispensably requisite.

This is the opinion of all practitioners who have any experience in diseases of the womb, to which many females in large towns are victims.

M. Lisfranc takes every opportunity of insisting on this important subject, and differs entirely from those persons who consider these diseases incurable, and leave persons afflicted with them to their fate. We have many examples to confirm us in our opinion, that uterine affections become incurable, might easily have been prevented, or their course arrested, had a proper degree of attention been paid to them at their invasion.—*Id.*

PRACTICAL CONSIDERATIONS ON THE SPONTANEOUS EVOLUTIONS OF THE FÆTUS,

In cases of presentation by the Shoulder,

By DR. P. DUBOIS.

In January last, M. P. Dubois made some practical observations on cases of presentation of the shoulder, in which the accouchement took place without the application of instruments.

In the majority of cases a natural accouchement is almost out of the question, when the shoulder is presented. Yet in the beginning of the labour the uterine contractions may still change the vicious position, and give a more suitable direction to expulsion of the fœtus; thus, the head may be bent, and gently pushed towards the superior strait, so as to engage it in a presentation by the summit; at other times the contractions carry their action on the inferior part of the fœtus, the head rises, and the pelvian extremities are engaged in the pelvis; in short, in a third hypothesis, the fœtus being very small, or in an advanced state of putrefaction, the head and thorax are engaged in the pelvis, and the accouchement takes place without the assistance of art, by violent uterine efforts.

These terminations do not constitute what accoucheurs have termed *spontaneous evolutions of the fœtus*. In cases in which the accouchement terminates spontaneously, which indeed seldom occurs, the first effect of uterine contractions is to press and diminish the size of the body contained in the womb. The head is bent, and the shoulder presented in the excavation of the pelvis as far the dimensions of this canal will admit. The uterine contractions continue, the fœtus then has a slight rotation; the head, which was placed transversally on the ischion, is immediately carried towards the symphysis of the pubis, and the shoulder passes under this bone. Then appear successively at the vulva the whole length of the arm, the side of the chest, the belly, the hips, and pelvian extremities; so that the trunk successively drawn towards the vulva, performs an evolution analogous to that of the head in presentations by the summit.

The mechanism of spontaneous evolution is, as we have before stated, a rare phenomenon on which we can only depend in certain circumstances, and which sup-

poses a pressure nearly always fatal to the fœtus contained in the womb.

If we consider that, in order to effect this expulsion, the amniotic fluid must have nearly passed, and that the child feels the violence either of the efforts of the uterus, or the bony canal to be gone through, it easily understood that in the majority of cases, the infant is lost; so that spontaneous evolutions, if a relief to the parent, is almost invariably death to the child; some children, however, do survive. Thus in thirty-seven cases of spontaneous evolutions related in M. Velpeau's work, seven or eight children were born alive.

There was a remarkable case of this description at the *Maternité*. A woman was brought to bed of a boy, the presentation was natural. A second child presented the shoulder, and was engaged in the depth of the pelvis. The uterine contractions soon made it follow the movements we have already indicated, and it came in world alive, and by the efforts of nature; but it was very small, and the way it had to pass through had been recently traced by the first child.

The possibility of spontaneous evolutions being established, practical conclusions, which may be useful in the obstetrical art, should be drawn from it, and those circumstances in which the efforts of nature may be depended on, should be well understood, for without this precaution, the knowledge of this fact may be productive of the most fatal results.

In the beginning of a labour it is very difficult, if not impossible, to guess the cases in which the efforts of nature alone suffice to expulse a fœtus, when there is presentation by the shoulder. They can only be supposed; the following signs for instance, may serve as a guide to this knowledge.

In cases of twins, this evolution may seem possible; when the woman is well constituted, and the child expelled is very voluminous, and the second presents the shoulder, it may reasonably be concluded that spontaneous evolution is possible; if, however, the efforts of nature were always depended on, the mistakes would be of a most serious nature.

When the infant has long been dead, this evolution may be possible; in these two circumstances only, we may suppose it can take place.

But when the labour is more advanced, there are circumstances which are much more conclusive. The first condition for the fœtus to be expelled is, that it should

not be too voluminous; that it should be very flexible, and that the uterine contractions should be very energetic.

When after the rupture of the membranes there is presentation by the shoulder, and the resources of art are not immediately resorted to, the uterine contractions force the shoulder as farward as possible to the pelvis, but the head remains fixed in the length of the pubis, and the majority of cases, notwithstanding the evidence of the pains, the fœtus keeps exactly the same place.

It is true that after prolonged efforts of the woman, on examination, the shoulder will be found deeper seated in the pelvis, not because the fœtus has changed place, but the parts are swelled, and consequently have penetrated deeply into the pelvis. This is almost constantly the case, and indubitably proves that the efforts of nature will not cause expulsion, and that the assistance of art is necessary.

But when the accouchement is to be natural, the shoulder reaches the excavations of the pelvis, and the arm comes down in full length, and these parts draw nearer and nearer, while the uterine contractions succeed rapidly.

These signs indicate that spontaneous evolution is possible: if the shoulder continues to descend, and that the side of the chest extends to the perineum, it may be hoped that the accouchement will terminate naturally.

It is most essential to ascertain when spontaneous evolution is possible, for by avoiding the introduction of the hand, the woman is spared violent pain, and the danger always attendant on such practice.

In fact, when the fœtus which presented the shoulder is pressed in the superior straight, and the uterine contractions do not propel it forward, version must be immediately resorted to. When, on the contrary, the shoulder is pressed in the excavation of the pelvis; when the arm comes out; and when, under the influence of pain, the side of the chest is pressed, the labour must be left to nature, and a difficult and dangerous operation is thus avoided.

This distinction is of the highest moment, for if practitioners neglected to attend to it, the consequences would be fatal.—*Id.*

OBSCURER MEDULLARY DISEASE
OF THE STOMACH.

BY JAMES JOHNSON, M.D.

A gentleman (Mr. Sandy) aged about forty-five years, became affected with uneasy sensations about the stomach or upper bowels, varying from an hour to three or four hours after taking food, especially the dinner meal. The pain was seldom acute, but rather it was a sense of distention, attend with eructations of air and acid, and continuing till the digestive process was finished. There was no vomiting or sickness—or scarcely any during the whole period of the disease, which lasted sixteen or eighteen months. At an early period of the malady, and many months before he came under my care, he passed, as was supposed, a mass of hydatids. It is probable that this was a mistake, and that the discharge consisted of gelatinous matters, which occasionally passed afterwards while I attended him. He had been attended by several medical gentlemen, none of whom could make up their minds as to the real nature of the disease, or even its precise seat. This was also the case with myself. When I first saw him, in July 1836, he was emaciated, sallow, and unhealthy in aspect. On stripping him there was no tumour visible or tangible in any part of the abdomen. But when he strained, there could be felt a very small induration, three or four inches above and to the left of the umbilicus, devoid of pain on pressure. This induration could not be always felt at first—but for the last two or three months of his life I could always feel it, and considered that it had got larger.

The phenomena of pain after food still continued, as well as the emaciation, without any fever or other constitutional derangement. About the middle of November he was seized in the night by syncope, and he was supposed to be dying. A surgeon in the neighbourhood was called up, and administered some cordial, by which he was revived. I saw him the next day, and found him much paler and more depressed than he had been. On examining the abdomen, there was a greater fullness in epigastrium than usual, but the distinct induration could no longer be felt. This puzzled me a good deal. There was no motion for three or four days, although opients were exhibited. At the expiration of this time a

large substance was passed, after great difficulty, together with much *fæces*, and, on examination, there appeared in the commode what resembled exactly about eighteen or twenty inches of the ileum inverted and reddened. It could be lifted up on a stick and handled, without breaking to pieces. This created alarm, and I was summoned. I could not, at first, determine whether or not it was an organized substance. It was taken to the Anatomical School in Kinnerton-street, and there washed and examined carefully. It was found to be a coagulum of blood, deprived of much of its colouring matter, and so exactly taking the mould of the small intestine, that the *valvulæ conniventes*, &c., of the bowel were most beautifully exhibited. On examination of the abdomen now, the fulness of the epigastrium was gone, and the original hard knot was felt as usual. The bowels now became regular and healthy, as well as the secretions. But the pain and sense of distention, some hours after taking food, became gradually more and more distressing, so that, for some days, he could hardly be prevailed upon to take any thing but liquids. After the complete digestion of the food, he got free from all uneasiness, and was cheerful and comfortable till the next day after dinner. All this time there was no sickness or vomiting; but the flesh gradually and steadily vanished, till he became a mere skeleton. In December and January last, the pain and sense of distention after food became so great that he was almost obliged to starve himself, to avoid the tortures of digestion. This, of course, accelerated the emaciation, and he died exhausted on the 13th January, 1837.

The body was examined next day by Mr. Henry James Johnson, and Mr. Hutchinson, of Farringdon-street—a gentleman who had formerly attended the patient. The following were the minutes of dissection:—

“1. Body much emaciated.

“2. No induration perceptible *after death*, through the abdominal parietes.

“3. *Abdomen*. The stomach was concealed by the transverse arch of the colon, which overlaid it, and which, at its left extremity, was bound down by adhesions in the left hypochondrium.

“The stomach was small. The left lobe of the liver was intimately united to it; the lesser omentum being almost obliterated.

“On opening the stomach, its internal surface presented numerous projections

of medullary structure, which extensively occupied the lesser, the greater curvatures, and the cardiac end of the stomach, as well as the termination of the œsophagus in the stomach. The mucous membrane covering the morbid growths was ulcerated, as were the morbid growths, in some degree themselves.

"The pylorus was healthy. The termination of the duodenum in the jejunum was adherent to the morbid growth of the stomach.

"The intestines were healthy."

There can be little doubt that the hæmorrhage which formed the remarkable coagulum some weeks before this gentleman's death, proceeded from one of the ulcerations in the stomach—and there is great probability that the supposed cluster of hydatids discharged at an early period of the disease, was only some morbid secretions from the stomach or intestines. None of the medical gentlemen who saw this patient hit upon the true true pathology, some considering it one thing, and others another. I could not bring myself to think the stomach itself was the seat of the disease, from the absence of vomiting, and from the long interval between the taking of food and the commencement of pain. The adhesions between the stomach and the left lobe of the liver, as also those which bound down the transverse arch of the colon that concealed the stomach, contributed much to the difficulty of diagnosis. The case, however is very instructive, as showing how accidental circumstances may render the diagnosis and prognosis most perplexing and erroneous.—*Medico-Chir. Rev.*

THE EFFICACY OF LOBELIA INFLATA IN INFLAMMATIONS OF THE MUCOUS LINING OF THE BRONCHIAL TUBES.

To Henry James Johnson, Esq., Lecturer on Anatomy, in the School of Kinner-ton-street.

Dear Sir,—I perceive from the Journals that a disease called Epidemic Catarrh, or Influenza, is very fatal in London—that it is attended with inflammation of the mucous membrane of the bronchial tubes—bears depletion badly—and that the old and infirm are the greatest sufferers. The experience and observation of a number of years devoted to the

practice of medicine, have led me to two important conclusions in regard to the principal diseases of the chest.

1st. That when the serous membranes of the chest are affected, tartar emetic and the lancet are worth all other remedies put together, and those cases which will not bear the lancet, will bear tartar emetic in considerable doses.

2nd. That in those diseases affecting the mucous lining of the bronchial tubes, the lobelia inflata comes as near being a specific as tartar emetic, and the lancet in pneumonia and pleurisy. As a remedy for asthma you are, of course, acquainted with the virtues of the lobelia inflata. The observation, that it holds a controlling power over inflammations of the mucous membrane of the lungs, has never, I believe, been announced to the medical world, and originated with myself. I always intended to make it known to the public. My notes of the efficacy of this remedy I left in the United States. If I had them, I could give you more definite and precise information in regard to the therapeutic properties of the lobelia in such affections. But I have thought that a bare enumeration of the principle, that lobelia inflata is almost a specific for inflammations and engorgements of the mucous membrane of the bronchi, and for spasmodic constriction of those tubes, might be attended with considerable benefit at the present crisis. I have very little doubt, that if the remedy be tested in your present epidemic, experience will establish the principle beyond cavil or dispute,—that lobelia inflata is, for inflammations and congestions of the mucous coat of the bronchial tubes, precisely what the lancet and antimonials are for inflammations of the serous membranes of the thoracic viscera. I have never found venesection, antimonials, or purgatives, of much utility in severe catarrhal fevers. Used with moderation, the effects of such remedies are often equivocal, and in excess, always prejudicial. You have, no doubt, observed, that in violent catarrhal fevers, the mucous lining of the alimentary canal sympathises with the inflammation of the mucous membrane of the lungs. Hurried respiration, red tongue, weak and frequent pulse occurring in catarrhal affections, especially in debilitated children and in old persons, always indicate considerable danger. This is precisely the pathological state of the system, which the lobelia inflata is so well calculated to remove. Its action is so prompt and self-evident, that there

can be no mistake about its virtues. It is altogether a different medicine in this state of the system, from what it is when given to a person in health or differently affected. In the healthy state the lobelia is powerfully emetic, but in the inflamed, congested, or spasmodic state of the bronchial tubes, it neither vomits, nor produces any sensible effect upon the great organs of secretion. It seems to spend its force in diminishing the anhelation, in lessening the frequency of the pulse, in allaying the general febrile commotion, and in restoring the balance of the circulation and excitability. Why it should do so, is as difficult to explain, as why opium is not a narcotic when it has pain or spasm to allay. I use a saturated tincture made of the leaves, stems, and inflated capsules of the plant. Dose—one or two tea-spoonsful every two or three hours, oftener, or not so often, according to the urgency of the symptoms. I mix it with an equal quantity of the syrup of squills, or the oxymel. I have given to children, less than a year old, from twelve to twenty drops, without producing vomiting. When the remedy vomits, it indicates that the dose is either too large, or the condition of the system is not applicable to its employment. It produces its best effects when it creates no visible constitutional disturbance. When the anhelation comes on in paroxysms, a dose or two or quinine may be safely and advantageously used in the intermission, and the lobelia in the paroxysms.

Most respectfully your
Obedient servant,
SAMUEL A. CARTWRIGHT, M.D.
Of Natchez, Mississippi.
—*Medico-Chir. Rev.*

SALISBURY INFIRMARY.

Case of Recovery from the Insensibility of Intoxication, by the performance of Tracheotomy.

By S. SAMPSON, Esq.

This case is contained in the last volume of the *Medico-Chirurgical Transactions*. It reflects much credit on Mr. Sampson, of Salisbury, and is physiologically, as well as practically, interesting.

Case.—“Abraham Harris, aged 31, was brought to my house on the 31st of

March last, in a state of complete insensibility from intoxication, the pupils being largely dilated, the breathing stertorous, and all voluntary motion having been lost for at least four hours before I saw him. The account given by those who came with him was, that he had attended a convivial meeting in the course of the day, at which he had drank freely both of beer and brandy; his companions admitted that he had taken more than a pint of the latter, but it has since been ascertained that his glass was repeatedly filled up, without his knowledge, with white brandy instead of water, so that it is impossible to calculate what quantity of spirit he had actually taken.

“I immediately used the stomach-pump, and drew off between three and four pints of fluid, a great part of which appeared to consist of brandy; after which tepid water, with ipecacuanha diffused in it, was several times injected into the stomach, and after a while withdrawn again, with a view to excite vomiting, and thus rouse the energies of the brain. Finding, however, that these means failed, a strong solution of salt in water, and afterwards the sulphate of zinc, was repeatedly tried, without any better result; but he became, if possible more comatose, the countenance turgid, breathing more and more difficult; the pulse grew fainter, and was at last scarcely perceptible; at the same time the whole surface of the body was cold and clammy and he was insensible to every kind of stimulus. As he was some miles from his home, I had him removed to the Infirmary, and called a consultation of the other medical attendants, who arrived in the course of half an hour; but as, in addition to the above symptoms, he had lost the power of swallowing, and every appearance indicated the rapid approach of death, nothing was ordered for him but a turpentine injection, there being no ground to justify a reasonable hope of recovery.

“At this period it occurred to me whilst standing by his bed-side, that the comatose state in which he lay might not arise from apoplexy, but from torpor of the brain, in consequence of that organ being supplied with blood not duly oxygenated; for the shrill tone and extreme difficulty of respiration shewed the existence of collapse of the glottis, and imperfect transmission of air into the lungs, which might be accounted for by a paralysed state of the eighth pair of nerves and recurrent branches. With this view of the case, I again appealed to my col-

leagues, and strongly urged that a trial should be given to the operation of tracheotomy; for I could not but hope that if mechanical respiration were carried on for a time, the blood might regain its proper stimulant properties, and restore the energies of the brain and nervous system. Upon their consenting to give him this chance the operation was performed, without loss of time, by Mr. Andrews, under whose care, as surgeon for the week, the patient was now placed.

"The trachea was no sooner opened, than the distention of the veins about the head and neck subsided, the violent efforts of the extra-respiratory muscles ceased, and in about half an hour regular and easy respiration through the wound was completely established; at the same time the pupils became slightly sensible to the stimulus of light, and the pulse returned to the wrist. The immediate result of the operation being thus far satisfactory, nothing remained to be done but to give directions for the frequent removal of the mucus which appeared at the wound, and to keep the surfaces of the incision asunder until the integuments and muscular layers had become agglutinated to each other; this latter object was effected by means of a piece of strong spring wire, with a bow at each end of it, which, being introduced in a bent state, was allowed to expand, and the opening in the trachea was thus prevented from being covered by the muscles, even during the efforts deglutition.

"He continued perfectly quiet during the night, but had no return of consciousness until the following morning, when he gave us to understand, by signs, that he suffered from headache and soreness at the pit of the stomach; there was a tendency to sickness, and the tongue was coated with a peculiar whiteness, as if rubbed over with chalk. Moderate purgatives, followed by mild alkaline medicines, soon removed these symptoms, and a few leeches were applied to the throat, for the purposes of checking too high a degree of inflammation; after which no further treatment was required; but the wound being healed in about three weeks he was discharged cured, and has continued up to this time in the enjoyment of perfect health."

We think there can be little doubt that the patient was dying of asphyxia, the result of the depressing influence of alcohol upon the brain and nerves. The opening made in the trachea facilitated respiration, by establishing an aperture, not muscular

and regulated by nervous influence like the glottis. In such a case, were the symptoms still more urgent, tracheotomy ineffectual, artificial respiration should, of course, be kept up. The effects of alcohol are transitory, and the view with which Mr. Sampson advised the operation is perfectly philosophical, and was, happily, successful.

BATH CASUALTY HOSPITAL.

Dissection of the Limb, twenty-one years after the External Iliac Artery was tied.

By G. NORMAN, Esq

On the 13th of September, 1813, Mr. Norman tied the right external iliac artery, after Mr. Abernethy's manner, for an aneurysm of the femoral artery, immediately below Poupart's ligament. The name of the patient was Hicks, his age fifty years, and his case was detailed in the tenth volume of the Medico-Chirurgical Transactions. The operation was successful, the disease never returned, and although there were several, slight threatenings of apoplexy, and habitual swelling of the feet and legs, the man lived until February, 1834, when he was carried off by cholera. The dissection of the limb is contained in the twentieth volume of the Society's Transactions. It is of course highly interesting, as an addition to our stock of facts.

Dissection.—"Independently of the appearances in the alimentary canal, characteristic of cholera, there was found some thickening and dilatation of the left ventricle of the heart, with deposition of body matter in the mitral valve. The arch of the aorta was somewhat dilated, and presented several patches of ossific deposit.

The arteries of the right lower extremity were filled with wax injection from the lower part of the aorta; the injection passing so freely as fully to distend the extreme branches in the foot and elsewhere. The following are the principal results of the subsequent dissection.

The external iliac vein was pervious, and presented nothing calling for remark.

The external artery was obliterated from the bifurcation of the common iliac to a point corresponding nearly to the lower edge of Poupart's ligament, and about one eighth of an inch above the origins of

epigastric and circumflexa ilii arteries; it there became pervious, and of equal size with the vessel in the opposite limb. The cord occupying the place of the obliterated vessel was of considerable size; the arterial coats perfectly distinct; and a probe introduced into its centre readily separated the adherent surfaces of the internal coat until it reached a point about an inch above Poupart's ligament, where all traces of the natural textures were lost, and replaced by a dense fibrous bundle.

About four inches below the crural arch, at the outer and posterior part of the femoral artery, was found a mass as large as a small walnut, composed of dense fibro-cellular substance: it involved the first part of the common origin of the profunda and external circumflex arteries, which, though obliterated, could be distinctly traced to the femoral. A portion of the profunda of about two inches was thus circumstanced; no injection having passed into it, and the remaining part of the vessel, which was of small size, being filled by the communication of its branches with other sources of supply.

The collateral circulation had obviously been mainly carried on by the ramifications of the internal iliac artery, which was nearly as large as the femoral. The manner in which it was affected may be described as follows:—

1. The ilio-lumbar artery, of very large size, gave several branches the lumbar plexus of nerves, descending in the substance of the anterior crural nerve as several elongated tortuous vessels communicating at the upper and outer part of the thigh with branches ordinarily derived from the external circumflex, and reaching to the fibrocellular mass already noticed. Other ramifications of the ilio-lumbar anastomosed with those of the circumflexa ilii, and also by that medium, on the one hand, with the inferior lumbar arteries, on the other, with the external circumflex of the thigh.

2. The obturator artery was proportionally much the largest division of the internal iliac, and with its branches very tortuous. Immediately before its passage through the obturator foramen, it gave off a large branch communicating with the epigastric at a very short distance from its origin, and forming apparently the chief source of supply to the epigastric, which was itself comparatively small. Directly after its emergence at the upper and inner part of the thigh, many of its external ramifications, much enlarged and very tortuous, inosculated freely with cor-

responding branches of the internal circumflex, also of a large size.

3. The gluteal artery was of average size: some of its anterior branches emerging on the dorsum of the ilium from among the gluteal muscles united with ascending branches derived from the external circumflex of the thigh.

4. The ischiatic artery was enlarged, and communicated tolerably freely with the posterior divisions of the profunda.

5. The internal pudendal artery was also of unusual size, and numerous tortuous twigs, collectively of considerable capacity, derived from its external branches, established a communication between the internal iliac and various branches, chiefly of the internal circumflex at the upper and inner part of the thigh."

We see nothing in this dissection, which calls for remark. It tallies with the experience drawn from the observation of other cases, and with what anatomy would lead us to expect. The re-establishment of the circulation through the agency of the circumflex and epigastric arteries, corroborates the necessity for caution in applying a ligature too near those, or indeed very near any large branch, in the operation for aneurism, or for wounds.

REVIEWS.

The Cyclopædia of Anatomy and Physiology. Part X. pp. 96. Edited by Robert B. Todd, M.D., Licentiate of the Royal College of Surgeons, Dublin; Professor of Physiology and of General and Morbid Anatomy in King's College, London; Physician to the Western Dispensary, and lately to the Royal Infirmary for Children, &c., &c.

The number before us of this work contains contributions from the pens of Drs. Coldstream, Dutrochet, Hart, Alison, Jacob, R. Owen, Esq., and the editor.

The article, Entozoa, by R. Owen, Esq., or, as we would rather designate the learned author, Mr. Owen, contains an accurate account of all that is known about this interesting series of animals. Although we cannot point out anything original in Mr. Owen's Essay, yet the order of perspicuity with which it is written, and the well-executed wood cuts with which it is actually studded, entitle it to our heartiest commendation. We

cannot but admire the great ingenuity Mr. Owen displays in introducing Sir A. Carlisle into his *bibliography*, although the worthy knight's name only figures in a small note appended to the *Tænia Solium*, and this in an article *sixty-seven columns* in extent. That Mr. Owen places little, if any, value on the labours and observations of Sir Anthony Carlisle is quite evident from his referring his readers to some musty book-shelf in search of "Observations upon the Structure and Economy of Tænia," in the second volume of the *Linnean Transactions* (1795!) instead of embodying in the text what was deserving of being culled from the original. Notwithstanding our being referred to "many beautiful preparations" "preserved in the Hunterian collection," it is impossible to gather from the grammatical construction of the note we allude to, whether the "GREAT ANATOMIST" or Sir Anthony deserves the merit of having "injected with coloured size and quicksilver," the "nutrient canals of the *Tænia Solium*." Upon the whole we are inclined to view Mr. Owen's reference, and to the lucubrations of the learned member of the Council and Court of Examiners of the Royal College of Surgeons as a mere bibliographical compliment; particularly as the results of numerous examinations made by Mr. Owen to decide "the chief point at issue respecting the digestive organs of the tape-worms," viz., "whether the nutriment is imbibed by them through the pores which occur at the sides or margins of each point, or whether the entire body is dependent for its nutriment upon the anterior mouths from which the lateral canals commence," have uniformly corresponded with those of Rudolphi, to whose opinion Mr. Owen "entirely subscribes," in considering "the lateral orifices of the segments as exclusively the outlets of the generative organs."

Notwithstanding the name of Dutrochet is identified with the article *Endosmosis*, upon which he writes, yet this fact is not sufficient to justify the Editor in imposing upon the patience of his subscribers twenty-five columns about what could have been as clearly and usefully embraced in less than half that number.

The same observations will apply with much greater force to the article *Extremity*, contributed by the Editor himself, which occupies thirty-six columns(!), and which, without any exaggeration, should have occupied not more than ten. Out of this number nearly thirteen

columns are taken up in describing the humerus, radius, and ulna; and even to this we should not be so much disposed to object, had there been a single redeeming feature in the shape of novelty of style, arrangement or perspicuity to compensate for the trouble of perusing the composition. But instead of one of these qualities—qualities esteemed in the present day as essential, not solely to perfection in composition, but to the rendering of the most unpretending essay at least intelligible; we are presented with a minute description of edges, which are always very imperfectly defined, and sometimes not present; grooves running in their wrong places, and but cursory allusions made to parts whose importance demands the greatest attention. These imperfections are the more to be regretted as the writer of them evidently wishes to appear anxious to smooth the path for his young reader; a desire which he thus expresses when speaking of the Fibula:—"A knowledge of the edges which separate these surfaces, will assist the student in understanding the position of the surfaces themselves."

One or two selections from the thirty-six columns will be quite sufficient to satisfy our readers that these remarks are not hyper-critical. In describing the humerus the learned Editor says,—"At the junction of the middle and inferior thirds we notice a very slight and superficial groove passing downwards and inwards, and very much resembling what one would imagine might be produced by an attempt to twist the bone while yet in a yielding condition, the inferior third having been twisted inwards and the two superior thirds outwards. This groove indicates the spiral course from above downwards and from without inwards of the musculo-spiral or radial nerve. Below this groove is the inferior third of the humerus, the anatomical characters of which are very distinct from those of the remaining parts of the bone. A prominent and rounded ridge, continuous with that already noticed in connexion with the greater tuberosity, passes vertically down in front of it; from each side of this ridge a smooth surface inclines backwards, forming an inclined plane on each side of it, the external being larger and more distinct than the internal."

Now if this "very slight and superficial groove" originates at the junction of the middle and inferior thirds of the humerus, and if the inferior third of the humerus is itself below this groove, we defy, not only

the student, but Dr. Todd himself, to point out the portion of the humerus it occupies; and for this simple reason, that, according to the description, there is no portion for it to occupy, for it commences at the junction of the middle and inferior thirds, and yet the inferior third is below it! This beat the Irishman's success when he shot at nothing! Had the Editor contented himself with saying that a shallow groove occupied the middle third of the humerus, giving the bone a twisted appearance, and that this groove corresponded to the course of the musculospiral nerve, every person would have known what was meant. And we would not even object to his saying that it was directed "from above downwards, and from without inwards," though probably the "above" and "without" are superfluous. In the description of the scapula we find the following:—"Above the spine of the scapula is the fossa supraspinata, which lodges the muscle of the same name, formed in front by the scapula, behind by the spine, both surfaces being slightly concave. Below the spine is the fossa supra-spinata much larger than the preceding, slightly convex, except towards its anterior part. This fossa is formed by the scapula below and the inferior surface of the spine above; it is limited in front by a ridge which proceeds downwards and backwards, from the glenoid cavity to the inferior angle, and bounds behind a surface which gives attachment to the teres major and minor muscles."

Was there ever such confusion as this? We are told the fossa supra-spinata is formed in front by the scapula, and behind by the spine; but we are directed to find it above the spine. When, according to the description, it should be before the spine. But to make the matter clearer, we are told that below the spine is the fossa supra spinata, and that this fossa is formed by the scapula before and the spine above. Now when it is the scapula itself which is under consideration, it is worse than faulty to say the whole scapula bounds part of itself. It would not be a whit more absurd, were we describing the liver, to say that the right lobe of the liver was bounded by the liver and so on.

We strongly recommend Dr. Todd to bestow his sole labour, in his capacity as Editor, to the very valuable work with which his name is in connection. We have every reason to believe he is most anxious to perform with skill and ability, the duties entrusted to him, and we trust

he will, in future, run no further risks of defeating any reputation he may have achieved as the Editor of such a work, or injure the reputation of its forth-coming numbers, by such contributions as the article *Extremity*.

Dr. Hart, as usual, gives a concise and interesting contribution. In the article "*Erectile Tissues*" everything worthy of detail is placed before us in a clear and off-hand style, and is perfectly intelligible to the meanest capacity. So very evident is this, that we cannot but say the note from the Editor is not only uncalled for, but shows a great want of judgment. Why is it that the contributions of Drs. Benson, Hart, and one or two others, alone are subjected to these unrequired and unasked for commentaries? We might be able to answer the question.

The article "*Eye*," by Dr. Jacob, it is hardly fair to say anything upon at present, as it will not be finished until the next number; but by way of hint to the testy little professor, we trust he will give the merit due to those individuals whose discoveries in the anatomy, physiology, and pathology of the organ, are full as likely to hand their names down to posterity, as that of the discoverer of the serous layer of the retina! We know that Dr. Jacob (for we have heard him and have copious notes by us) in his lectures on the Eye, has been in the habit of indulging to excess in the freest criticisms on others. Whether it is his intention to do so in the continuation of the article, it is not, of course, our lot to know; but by way of a guide we beg to quote the authority of a lecturer and a writer, whose name will live as long as surgery is a science. Mr. John Bell in the preface to his work on wounds, says, "the author has used all that freedom with great names which the cause of truth and science requires: he has published boldly many criticisms, which he would not have ventured to mention in his lectures, or in private; for there criticism is no longer criticism, but the foul report and private malice of it works like a secret poison, against which there is no preventative or cure."

The article "*Excretion*," by Dr. Alison, like everything which comes from his pen, is clearly conceived, and elegantly executed. Its extent is twelve columns and a half.

The manner in which this, and the preceding numbers of the work, are published—the clearness of the type, the correctness of the wood cuts, and the quality

of the paper, are excellent. We conceive that Messrs. Sherwood, Gilbert, and Piper deserve well of the profession, and, we are sure, will receive its support. It is with every wish for the success of "The Cyclopædia of Anatomy and Physiology," that we have thus freely criticised the present number, and we trust that in future the sole care of the Editor will be directed to the important position he is placed in, and not allow a desire of figuring in print, to interfere with the duties he has undertaken.

Ueber die Ursachen der grossen Sterblichkeit der Kinder des ersten Lebensjahres. 8vo. pp. 111. St. Petersburg, 1837.

For the Treatise before us Dr. Lichtenstaedt received the prize from the Imperial Economic Society of St. Petersburg. It contains a statement of the gross mortality among children in the initial period of life; its causes, natural and artificial; together with the means of remedying it. In Russia the proportion of deaths during the first twelve months of infancy is 270 in one thousand; which is above one-fourth of the whole.

De Ictero—Dissertatio Inauguralis, ab F. W. R. Riese, M.D. 8vo. pp. 30. Kiliae, 1836.

The author, in this thesis, gives a succinct account of the nature, symptoms, and treatment of jaundice.

To facilitate the evolution of gall-stones he recommends, on the authority of Durandus, the internal administration of 10—30 drops of the following mixture, frequently repeated and combined with whey:—

(Recipe)

Æth. Sulphur.

Ol. Terebinth. $\bar{a}\bar{a}$ partes æquales.

BOOK FOR REVIEW.

Supplement to the Flora Metropolitana; or, Botanical Rambles within Thirty Miles of London.—Containing an Index of both Latin and English names, time of flowering, and colour of the flower of the Phænogamous Plants enumerated in the Flora; with many new

and additional localities procured last summer; and the height of the principal hills, &c., round London. By Daniel Cooper, A.L.S., Curator to the Botanical Society of London, &c. 12mo. pp. 36. Highley, London, 1836.

HYDROPHOBIA IN A CHILD.

The following singular case has lately occurred in Suffolk:—A little girl named Burch, about four years old, the daughter of a ship-wright residing in the Back Hamlet, died on Monday last, of hydrophobia. About two months since, the deceased, while teasing a small dog belonging to her brother, was bitten in the lip; and although the animal had not exhibited any appearance of madness, the parents had it destroyed. Surgical assistance was called in, and the child's lip sewn up; it soon healed, and she enjoyed excellent health until Saturday last, when she complained of illness. The distressing symptoms of the malady rapidly increased, and on Monday the paroxysms were frightful in the extreme. She was visited by most of the medical men in town, but their assistance was unavailing, and at four o'clock death put an end to her sufferings. We understand that the mother of the little sufferer, had just been confined with her eighteenth child, but only four are living.

[This is a very remarkable case, and shows the obscure nature of hydrophobia. It does not accord with the pathology, that the disease is a purely nervous or mental affection, as some have supposed.—*Ed.*]

CANTHARIS.—If we trust the experiments of M. Tommaso Pullino, cantharis must hereafter be considered as a most powerful antiphlogistic, instead of being one of the most violent and dangerous irritants. He mentions three or four cases in which he gave it a trial, in one (pleurisy) administering as much as eighty-five grains in sixteen days; his account is however very unsatisfactory. If carried too far, it produces stranguary, vomiting, small and frequent pulse, shiverings, vertigo, torpor, &c. &c.—*Annali Universali di Medicina.*

SEMEIOLOGY.

Physiological Symptoms of Disease—Alterations in Sensation—Setting of the Teeth on Edge—Formication—Aura Epileptica—Sensation of the Foot being asleep—Tenesmus—Bad taste in the mouth—Itching—Cardialgia—Nausea—Looking glass of the stomach—Rationale of cold effusion in fever—Action of Emetics and Opium in cutting short a fever—Catarrh cut short by snuff—A stitch in the side—Spasm of the Diaphragm—Congestion of the Spleen—Sighing—Gaping—Hiccup—Angina Pectoris—Anxiety—The fidgets—Anxietas Labiorum—Alterations in thought—Morbid vivacity, hebetude, and Perturbation of thought—Insanity, delirium, Hypochondriacism, and idiotism—Alterations in voluntary motion—Fractures and Dislocations—Tetanus, epilepsy, hysteria, chorea, and palsy—Therapeutics—Difference between a remedy and an exciting cause—Indicatio morbi—Consilium medendi—Indications of cure—Prophylactic curative; palliative and conservative indications—Dietetic, pharmaceutic, and surgical remedies—Hygiene—Phlogistic and antiphlogistic remedies—Baths—Cold, temperate, tepid, and hot baths—Highest temperature of a bath—Hot baths in luxations, cutaneous diseases, diabetes, and rheumatism—The Douche—The employment in mania—George the Third—Air—Change of air in Phthisis, chlorosis, dyspepsia, jaundice, hypochondriasis, and hooping-cough—advantage of smoky air in asthma—Gases—Disinfection by camphor, sulphurous acid, muriatic acid, nitric acid, oxygen, chloride of lime, chlorine

No. 14.

and acetic acid—Thieve's vinegar—Diet—Diseases which require a vegetable, and those which require an animal diet—Animal principles—Principles which are most nutritious and least digestible—Dogs starved by too nutritious a diet—Proper diet for convalescents—Chickens not good in chlorosis—Advantages of grated beef—Scurvy from beef tea—Vegetable principles—Composition of gluten—Varieties of starch—Plants which yield arrow root, sago, tapioca, and salep—Cookery—Best mode of preparing food—Broiling, frying, roasting, boiling, baking, and stewing—The passions—The royal disease—Employment of the passions in nervous diseases, hernia, dislocations, and anticipated rupture of the uterus—Quack medicines—Efficacy of bread pills—Mesmerism and metallic tractors—Exercise—Circular swinging in mania—Shampooing—Medicines—Modes of administering medicines—Homœopathia—Instances of diseases which are caused and cured by the same medicines—Evacuant medicines.

(3.) Titillatio gingivarum, or the setting of the teeth on edge, is owing to unpleasant sounds conveyed from the ear by the chorda tympani. That these sounds produce a disturbance of the circulation of the blood in the gums, is shewn by the fact, that this affection of the gums sometimes goes on to hæmorrhage.

(4.) Formication comes on in the first stage of cutaneous diseases, before the eruption appears; and in fever before the hot-fit comes on.

(5.) The aura epileptica is owing to the abstraction of the nervous stimulus derived from the brain, in consequence of which sensation and voluntary motion cease; and the vessels at a distance are the first to feel the loss of this stimulus. This sensation does not follow any particular nerve, but creeps under the skin, where the nerves are sufficiently sensible to feel the retention of the blood.

(6.) The sensation of the foot being "asleep," is a minor degree of the aura epileptica; pressure on the nerve of the leg having obstructed the passage of the stimulus from the brain. It occurs likewise in myelitis.

(7.) Tenesmus occurs, not only in diarrhoea and dysentery, but in pressure on the rectum, from scirrhus of the prostate gland, or from retroverted uterus; for the nerves of the part are capable of only one kind of sensation, whatever may be the nature of the stimulus applied.

(8.) A "bad taste in the mouth," is from vitiated secretion.

(9.) Itching of the skin is likewise from vitiation of the secretions, and comes on when a disease is going off, having terminated in secretion.

(10.) Cardialgia is from irritation of the coats of the stomach, from the vitiated secretion of muriatic acid. Use magnesia if the bowels are confined, because the muriate of magnesia which is formed, will open them. If the bowels are not confined use lime. Dr. Home recommends ammonia in these cases.

(11.) Nausea is owing to constriction of the vessels of the stomach, which excludes the blood. It comes on before vomiting, on the application of a strong stimulus, and in the cold stage of fever, in which case both the stomach and the skin have less blood than usual. On account of the great sympathy between the two latter, the skin is said to be the looking glass of the stomach. The cold stage of fever may be cut short by means of cold effusion, which makes the vessels of the skin and stomach contract to a degree incompatible with the longer continuance of the constriction. The hot-fit, therefore, comes on, and thus we substitute a milder fever for a severer form. A man gets a small fever every time he goes into a cold bath. Emetics and opium have the same effect in cutting short a fever, but they act on the skin indirectly, through the medium of the brain and stomach. On the same principle of causing a great constriction of vessels, a man not accustomed to take snuff, might cut short a catarrh by using it.

(12.) A stitch is a short spasm of some of the fibres of the diaphragm. Mason Good ascribes it to congestion of the spleen; but if that were the case we should have it regularly after meals, and it occurs as often on the right side as on the left. Sighing, gasping, hiccup, and angina pectoris, are all different degrees of affection of the diaphragm. The same

cause (exercise, for instance) which gives a boy the stitch, will give an old man angina pectoris.

(13.) Anxiety arises from the retention, in any organ, of its natural stimulus; as in the lungs, bladder, and rectum. It is well seen in the cold stage of fever, in diseases of the heart, and in dyspepsia, after dinner. General anxiety, or "the fidgets," is from the retention of blood in the veins. It is excited by sitting still, or by the expectation of a letter, or by listening to an old story, or by fever in its cold stage. All these abstract nervous energy from the system; and the venous circulation, being the least energetic, is the first to suffer. *Auxietas laborum* is very common in elderly females, and to relieve it they put one leg over the other, or lie on a sofa, or apply friction.

6. *Alterations in Thought.*—There may be either morbid vivacity of this function, morbid hebetude, or perturbation. Thought is preternaturally acute, whenever sensation is excited; and it is obtuse whenever sensation is depressed. It is irregular in insanity, delirium, and hypochondriasis. Idiotism is the best example of morbid hebetude of thought.

7. *Alterations in voluntary motion.*—These may arise from either of two causes. 1. *Adventitious causes*, as fractures and dislocations. 2. *Morbidly increased*, morbidly diminished, or irregular contraction of the voluntary muscles; as in tetanus, epilepsy, hysteria, chorea, and palsy.

THERAPEUTICS.

A remedy differs from an exciting cause of disease, only in the different degree in which they are applied, and the different circumstances in which they act. The *indicatio morbi* (or indication of the disease) was thought by Galen to be a display of what the disease required for its cure. The latter is now generally called the indication of cure (or *consilium medendi*). The indications of cure of four kinds:—1. Prophylactic; 2. Curative; 3. Palliative; 4. Conservative. The latter are designed to guard against relapse. We fulfil these indications by three classes of remedies:—1. *Dietetic* remedies, or hygiene; 2. *Pharmæutic* remedies, or medicines; 3. *Surgical* remedies, or surgery.

I. *Hygiene.*—This may be either phlogistic or antiphlogistic. We shall consider the various remedies which come under the head of hygiene, in the same order in which we took up the stimuli to

Irritability, and the Exciting Causes of Disease. 1. Caloric, and its abstraction (or heat and cold), including climate, situation, dress, bathing, &c. 2. Air, which comprises disinfecting gases, &c. 3. Aliment, which must be full or sparing in different circumstances: cookery falls under this head. 4. The passions, through the medium of which various modes of charlatany exert their influence. 5. Voluntary motion, under which gymnastics and exercise of various kinds are to be considered.

1. *Baths*.—These are variously named, according to their different degrees of temperature. 1. Cold bath, up to sixty-five degrees. 2. Temperate bath, from sixty-five degrees to eighty-five. 3. Tepid bath, from eighty-five degrees to ninety-five. 4. Hot bath, above ninety-five degrees. The highest temperature that can be borne by the skin in a bath, is about a hundred and ten degrees. This is prescribed by Sir Astley Cooper in luxations. The hot bath is used in fever, cutaneous diseases, diabetes, and rheumatism.

2. *Douche*.—The douche is performed by pouring a small stream, from a height, on the head, while the rest of the body is kept warm. It was brought into use for mania, and its inventor wished to try it on George the Third.

3. *Air*.—Change of air is favourable in phthisis, chlorosis, dyspepsia, icterus, hypochondriasis, fevers, pertussis, and in convalescence from all diseases. In asthma, some persons do better in a pure air, others in impure; and, as Dr. Home says, this, as well as all other remedies, must be regulated by the previous experience of the patient. He relates the story of an old asthmatic lady, who was cured by getting into a gypsy's smoky hut; probably from the smoke being a stronger stimulus. Frequently in hooping-cough, a change of air removes the titillation of the fauces, by changing the stimulus; as in the case of ulcers, the substitution of even a weaker lotion for a stronger will often prove beneficial.

4. *Gases*.—Various gases have been used for the purposes of disinfection. 1. Vapour of camphor, by the Arabians. 2. Sulphurous acid, by Home. 3. Muriatic by Guyton Morveau. 4. Nitric acid, by Carmichael Smyth; who obtained a reward for recommending it, although it had been employed thirty years before by Pringle. 5. Oxygen, by Selle. 6. Chloride of lime, by Labaracque and Alcock. Chlorine, by Cruikshank. Acetum aromaticum has been called "thieves' vine-

gar," because it was used by the thieves at Marseilles, during the plague, to protect themselves from infection. Home recommends a sponge to be filled with it and suspended in the room which is sought to be disinfected.

5. *Diet*.—The diseases of repletion are polysarcia, calculi, &c., and these require a vegetable diet. Dropsy requires an animal diet. The following is a list of the animal principles, in the order of their nutritious properties:—Gelatine; 2. Albumen; 3. Stearin; 4. Elain; 5. Osmazone; 6. Fibrin. Stearin and elain exist in combination in the form of fat. The digestibility of these principles, is in the inverse ratio of their nutritious properties, so that gelatin, although the most nutritious, may not nourish most, the stomach not being able to digest it. Barry says that an animal may be starved, by giving it food too nutritious, or too concentrated. The dogs which Magendie fed wholly on sugar died of scurvy. Hence it is not good to give convalescents food of too nutritious a kind; and Dr. Baillie recommended "a tough old cock," in preference too a chicken, for a chlorotic patient. Grated beef on bread and butter, as containing a good deal of fibrin, would be better. Brodie boiled some beef to rags, and gave the liquor to six dogs, and the meat to six others; the former died of scurvy, the latter did well.

The following are the chief vegetable principles. 1. Fecula; 2. Glidine; 3. Zimome; 4. Gum; 5. Sugar; 6. Lignin; 7. Fungin. This is found only in cryptogamic plants, and stands in the place of lignin. Gliadine and zimome constitute gluten. Fecula is of various kinds, and is obtained from various plants. 1. Common starch, from the germinæ, and solanum tuberosum; 2. arrow root, from the maranta arundinacea; 3. Sago, from cycas circinalis; 4. tapioca, from the tatropha Manihot; 5. Salep, orchis mascula, and orchis Morio.

6. *Cookery*.—Broiling is the best mode of preparing food, because it retains all the fibrin. Frying is the worst, because it leaves all the indigestible matter, and adds, oil or some fatty mater, which is more so. Roasting, boiling, baking, and stewing, are intermediate between broiling and frying.

7. *The Passions*.—Jaundice was formerly called a royal disease, because the person affected with it was recommended to live a kingly life, "ludis jocis et omni-lascivia." The passions are made use of in the treatment of dyspepsia, hypochon-

not take place; this air will prove destructive by different modes:—1st. By preventing respiration; for if many substances are volatilized, the air containing them will not reach the lungs, except in too small quantities for the support of animal life. 2ndly. By specific poison, producing a variety of diseases, often sedative, as debility and agues, in marshy grounds: in other places, fluxes and different kinds of poisons. 3rdly. The effects of an impure atmosphere are found in jail distempers and hospital diseases; very few of the former places are even free from foul air, and most hospitals are more or less affected with it. There are different modes in which these poisons may affect. A stranger in a marshy country is much sooner affected than a native or an inhabitant. A person who has not long been used to a jail will earlier, and with more certainty, be affected with jail distemper. An instance of this occurred at Salt Hill, in 1760. The effects at first were attributed to the wine; but they were evidently caused by a few paupers, who were examined by some gentlemen, although the paupers did not appear to be affected. In 1775 some prisoners were examined at the Old Bailey, who infected the whole court, and many died; the judge on the bench, the jury, and evidences, &c. Many poisons are of this kind; a person may carry the infection about with him without being affected himself. The air is capable of carrying most poisons, and communicating their irritations. The venereal poison cannot be thus raised in a state of vapour, or if it can, it loses its effects in the change.

Perhaps next to never coming within the influence of such effluvia at all, it is safest to live surrounded by them in large cities, where, either from the habit of being exposed to their action, or from one effluvia destroying another, the effects are prevented from taking place to the extent that might be expected. However, if the atmosphere, being impure, produced an effect only on those coming into it, all the old residents would be equally healthy as the strangers who come to reside for a time only; yet this is not the case, for they are by no means all robust; therefore what may be styled its unfitness produces a debility, and the persons are neither so strong nor so healthy as those resident in a healthy atmosphere, though they feel not the sudden effects with which strangers are attacked.

We have a kind of atmosphere which spreads over various countries or climates

in particular seasons only, as lately over England. These have had different names at different times; we call it the influenza: it affects at first dogs, then horses. In 1775 the dogs were all ill, and afterwards the horses, before men felt the influence of it.

The atmosphere is the menstruum for various substances, some of which are held in a state of solution, and others in a state of mixture only. Water is held in solution in the atmosphere, and when much of this is suspended, it renders it heavier, as the barometer shows; and when a decomposition of the solution takes place, the water is precipitated as rain or snow, and the air is made lighter, as the barometer also shows. This decomposition may take place, although neither snow nor rain is produced, and this in consequence of a fresh combination taking place before the ultimate end is produced. When the above decompositions take place, the birds and beasts seek their shelter; and an effect is produced on wounds, particularly when in a healing state, and in diseases and ailing parts of the human body, so that persons become, as it were a weather-glass. We have lately been informed by a German, that the variations of the magnetic needle have appeared so much to vary with the changes of weather, that as much might be learned from it respecting the prognostics of the weather as from the barometer itself. Winds may be easily supposed to bring with them the effluvia of disease. Extraordinary effects are produced by the Harmattan wind, a wind which blows off the interior part of Africa to the coast of Guinea. It generally comes three or four times a year, at certain seasons; it is always attended with a fog, which has no taste, nor could anything be discovered in it by means of glasses thinly covered with molasses. The fog is thickest on the beach, and gets tolerably thin about four miles inland. It lasts often for a fortnight, and produces a pain and dryness in the mouth and nostrils, not as if from mere dryness, but as if from some acridity. If it continues three or four days, the scarf skin falls off, and the tongue applied to that part of the skin denuded of cuticle is sensible of an acrid taste. Though very prejudicial to vegetable life, it is salutary to animals, curing fluxes and other epidemic disorders, and often restoring weakened constitutions. Fevers which had been imprudently reduced by bleeding, got well in spite of the doctor. The small-pox always yields to it, while it

prevented the inoculation from taking effect in some African slaves. Such as were inoculated before the Marmattan set in had the small-pox, and all did well; but such as were not then seized with the symptoms, and these were sixty in number, never felt any other affection but a slight fever and nausea during the continuance of the wind; after which it showed itself in twenty of them: the others were inoculated, and all did well.

GENERAL PRINCIPLES OF DISEASE.

Now that I have treated some of the properties of the animal in health, I shall go on to treat of its imperfections, or diseases. To understand these it was necessary, in the first place, to describe its perfect or healthy state. To describe the parts in a healthy state belongs to the anatomist; their actions in this state to the physiologist; but the diseased state of these actions, and the restoration of parts to health, to the physician and surgeon.

It is hardly to be supposed that disease is ever natural to an animal; it can only be the consequence of some unnatural impression which interferes with the natural action of the body, which impression may take place at the very first formation, or original arrangement of the animal, so as to stamp a permanent unnatural action; or it may take place in the first life, namely, in utero; but much more frequently after birth, when it is exposed to a thousand variations, all of which are impressions, and are contrary to the natural actions of the animal, or are, as it were, a forcing it to take on actions, which are either to remove those impressions or to destroy itself.

It is most probable that diseased actions are established on nearly the same principles that the actions of health are. They are at least similar in a great many of their principles: they destroy the dispositions of parts; they produce growth; they produce the power of removing natural parts; they are ruled by habit; they are affected by every external influence.

An animal is so constructed as only to continue some diseases so long as the immediate cause lasts, as in scrofula, when it arises from climate; or which is so constructed as to continue other diseases from habit, as gleet, so as to go on with a disease, although the first cause is gone; and this may be only for a time, as in gonorrhœa; or it may be for ever, as in lues, cancer, &c.

Diseases are either common to all parts

alike, as inflammations of all kinds; as, also, tumefaction, scirrhus, dropsies, &c. The peculiar are those in which there is a fault in the peculiar actions of a part, as involuntary action of voluntary muscles, too much or too little secretion from any of the glands, in short, wrong actions of any part in its peculiar mode of action.

After the disposition, the action which should destroy the disposition takes place; the action having taken place, the disposition ceases and the natural action of the parts returns. But this is not always the case. The disposition may be affected in one of the following ways: 1st. The action may destroy the disposition, for instance, in gonorrhœa, (and perhaps in many other complaints); in this case the action destroys the disposition, or the inflammation destroys the disposition of the virus. 2dly, The disposition is destroyed for a time, and returned at intervals, or after certain spaces, as in all periodical diseases, or others where the disease ceases for a time, and the disposition continues. 3dly, Where the action takes place, yet does not destroy the disposition, as the venereal disease, which goes on till it is cured or kills, and the action of it never destroys the disposition.

Many diseases often require their full action before they produce their effects, as the gout and many agues. Vomiting is the action following the disposition to sickness, and is often its cure, for without it the nausea and disposition will continue. Sometimes chronic diseases will be cured by acute ones, in which case, the full action being given, the disposition is removed.

General Observations on Susceptibility and Disposition, constituting Constitutions, and on Actions forming Symptoms.—The physiology of disease is more extensive, more obscure, depends less on general laws of nature (being often a prevention or perversion of those laws), and is therefore more irregular than any part of science, and is of course less understood.

The most simple idea I can form of an animal being capable of disease is, that every animal is indued with a power of action and a susceptibility of impression, which impression forms a disposition, which disposition may produce action, which action becomes the immediate sign of the disease; all of which will be according to the nature of the impression and of the part impressed.

That every action, whether natural, preternatural, or diseased, arises from this

susceptibility of impression, I think we must allow, which susceptibility may exist without even disposition or action, if no impression or stimulus is made; for the disposition is only formed in consequence of some impression, and the action is only the consequence of the disposition being so strong as to incline a part for action rather than for resolution. Therefore action is the ultimate consequence of impression being made on a part endued with a susceptibility of impression and the power of action, which impression gives them the disposition to act. For from what was said above, parts having susceptibility do not necessarily have the disposition; the disposition arises from some impression, which will, in its turn, produce the action, and this action, or disposition to action, must be sufficient to overcome the natural and habitual actions of the part or whole, just as force overcomes the vis inertiae of matter. But susceptibilities are in some so strong as almost to approach a propensity to act, which is probably as strong as the disposition, or often probably stronger.

The actions of the body, and the cause of these actions, with their effects, are exactly similar to those of the mind, and as we are sensible of the actions of the mind themselves, abstracted from their causes or effects, we reason about them as much as we can reason about their causes and effects. This is not the case with the actions of the body, for in them we are only acquainted with the causes and effects, not the action itself; therefore our minds are only reasoning about them from analogy.

The susceptibility for action of the mind is not known to the mind itself, but by the consequence of such susceptibility. Some minds are much more susceptible of certain actions than others; thus, some men are more susceptible of anger, others of love. But this does not imply that one mind is always in anger, another in love, &c.

With this susceptibility of mind, a stimulus must be applied to produce the disposition to action. A stimulus of one kind will produce anger, of another kind, love. The action of the mind employs other parts to complete the whole, as when the actions of the mind are employing other parts to produce the ultimate effects. But there are not necessary to the action of anger, for anger could exist without the action of employing other parts, and indeed continue longer; for this tends to destroy the action

of anger, because the effect being produced the cause ceases.

Every animal has a variety of susceptibilities which admit of a variety of impressions, each impression producing a disposition peculiar to itself. Also every animal has some of those susceptibilities stronger than it has others, out of all which a vast variety of diseases is produced. Each tendency to a peculiar mode of action gives the character of the animal respecting disease. The sting of a bee, for instance, affecting some people much more than others, demonstrates that there is a susceptibility in some for such actions more than in others. In many the susceptibility will be so strong as only to require a stop to be put to the natural actions, when the disposition and the disease too will take possession of the part or of the whole. An instance of this we have in scrofula, for it often happens that common accidents, as strains, bruises, fevers of all kinds, produce the disease even in situations the most calculated to prevent it, as in the West Indies. Even poisonous dispositions are produced in this way, a blow on the breast or testicle shall produce a poisonous mode of action, e. g. cancer.

From this account no animal is formed with a disposition for the action of disease. The natural actions are for the good of the animal; but they can be perverted, they can be made to destroy the whole. These circumstances are similar to those of the mind; some minds are more susceptible of some impressions than they are of others, which produces a disposition to act, which action will be according to the impression. The susceptibility of the constitution may be increased, so as almost to be similar to a new formation, but is never originally formed, by art. Where the susceptibility is weak, it may be increased and kept so much on the brink of forming the disposition, that it shall only require the least increase, or some other immediate cause, to produce the effect or form the disposition, as a man not naturally fearful may be worked upon so that the least thing may alarm him. Susceptibilities may be so increased as almost to deserve the name of acquired; constitutions long habituated to particular climates will form a scrofulous habit, or an aguish habit, and a certain way of life will produce a rheumatic or gouty habit. On the other hand, persons naturally susceptible may be made by degrees considerably less so, by being gradually accustomed to the

immediate cause, beginning within the degree of impression necessary to excite disposition to action.

There is no such thing, strictly speaking, as a predisposing cause. What is commonly understood by a predisposing cause is an increased susceptibility to form disposition to action: When I say I am predisposed for such and such actions, it is only that I am very susceptible of such and such impressions, which impressions must form the disposition; or if it is intended to dispose a person for such and such actions, it is only to render him more and more susceptible of such and such impressions. The susceptibility must always precede the disposition. A disposition is a determined thing,—a thing formed,—a kind of resolution.

Of Susceptibilities of Parts and Constitutions for different Actions.—Every constitution is more susceptible of some constitutional actions, both natural and diseased, than it is of other actions, whether natural or diseased; and every constitution is more susceptible of some local actions, natural and diseased, than it is of others.

Every constitution is compounded of parts whose natural actions are very different from one another. Thus, the natural actions of the liver are very different from those of the lungs. Therefore we also find the diseased actions of one are often different from those of the other; although every part of the body may be subject to some one or more common diseased actions, as e. g. the liver and lungs, which may be subject to common inflammation, or they may both have the specific disease, as scrofula.

Every constitution being composed of different parts, whose natural and diseased actions are different from one another, as above mentioned, these actions being according to the nature of each part, and each part in some constitutions being more susceptible of natural actions peculiar to itself than the same part in other constitutions, so also in some constitutions each part is more susceptible of its diseased actions than the same part is in other constitutions. Thus, as the liver in some constitutions is more susceptible of secreting bile, which is its natural action, than it is in others, so also it is more susceptible of its peculiar diseases in some constitutions than it is in others. Constitutions may be said to be more or less susceptible of this or that universal action, among the first of which may be marked the irritable and the indolent.

Secondly, some constitutions are more susceptible of some diseases than others are of other diseases.

Thirdly, some constitutions are more susceptible of some diseases than others are. And those constitutions not susceptible of this or that disease may be at the same time more susceptible of some other diseases than the first-mentioned constitutions are. For example, some constitutions are more susceptible of inflammatory fevers than of any other fevers; others are more susceptible of putrid fevers; while either one or the other of these constitutions might have some other disease, either violently or mildly, as small-pox, measles, &c.

Constitutions may be more susceptible of some one specific disease than the same constitution of other specific diseases, e. g., some constitutions are more susceptible of small-pox than of measles, or *vice versa*.

Some constitutions may be more susceptible of some specific disease than other constitutions are, e. g., some constitutions are more susceptible of the small-pox than others are, and yet have the disease mildly.

All of which characterize the constitution at large.

Of universal Susceptibility to produce local Diseases.—Bodies may be said to be both constitutionally and locally susceptible of diseased action. The erysipelatous fever, which is constitutional, being attended by the erysipelatous inflammation, which is local, is a strong instance of this.

Constitutions are more or less susceptible, both universally and locally, of the same disease, as the small-pox fever, when violent, has more violent and extensive local effects; when mild, more mild local effects.

Constitutions may be said to be more or less universally susceptible of this or that local action, when one part takes on action without any visible immediate cause, or when any injury (whether constitutional, as fever, or local, as accident,) makes parts so injured run into a much worse diseased state than the same injury would have done in others; many parts even taking on specific diseases, whenever the immediate cause is produced, as scrofula, venereal gonorrhœa, &c.

Constitutional susceptibilities for diseased actions may be divided into three kinds, and there are also others which are mixed.

1st, *An original constitutional*; that

is, where there is a universal susceptibility for diseased action of one kind or another, in which, however, the whole must be in action, as inflammation, fever, small-pox, &c.; also sympathetic fevers of all kinds. Persons may be very susceptible of the whole of these, or only of one or more.

2nd, *Original local*; that is, where the whole is so constructed as to be universally susceptible of going into diseased action in any one part; but the actions will be always local and independent of every other part, as scrofula, gonorrhœa, or chancre. Hence the venereal disease is worse in one than another, and yet is local; the same with scrofula.

3rd, A susceptibility to fall into universal indisposition, as if there were something teasing the whole; which can then call on a part, and that relieves the whole, as in gout, rheumatism, and perhaps all those diseases where the local action is critical. Most of these can be relieved by a universal facility to action, or retarded by the contrary, which affect either the local action or the constitutional one.

OBSERVATIONS ON EPILEPSY,

MADE AT THE HOSPITAL DE BICÊTRE, IN
THE YEAR 1829.

By W. MURDOCH, M.D.,
Formerly Interne in the French Hospitals.

There are certain diseases of which the study is neglected by professional men, either because they are considered incurable, or on account of their rare occurrence, both in private practice and in the establishments destined for the reception of human sufferers. Epilepsy is one of these afflictions; and if we run over the nosological table we shall not find another so degrading to our species, so dreadful in its symptoms, and so appalling in its consequences. There is something indeed frightful when an individual, apparently in all the vigour of health, suddenly falls to the earth, his whole muscular system is violently convulsed, his mental faculties suspended, his face livid and distorted, his respiration laborious, and his life endangered. This state continues a few minutes, more or less, according to circumstances, and he then gradually comes again to himself, and after a long stupor, returns to his usual

intellectual and bodily habit. Such as an epileptic fit, and a succession of these fits, occurring at regular or irregular periods, constitute the disease called epilepsy, from *επιλαμβάνω*, to seize upon. No wonder that in times of ignorance persons tormented with this malady were looked upon as possessed with an evil spirit, that the names of *morbus herculeus*, *sacer demoniacus*, were given to it, and that the superstitious Romans used to suspend the deliberations of the forum when any one present was seized with epilepsy, hence the appellation *morbus comitialis*. The French authors have distinguished two forms of epilepsy, to the first of which the symptoms have been just enumerated, they have given the name of *grand mal grandes attaques*. It is decidedly the most common. The other has been called *epileptiform vertigo petit mal, petites attaques*. It consists in a sudden suspense on perturbation of the intelligence, with relaxation of the muscles. The patient is not convulsed, often does not fall, but recovers himself in a few seconds. Some are not inclined to admit this division of epilepsy into two species, because the second variety almost always accompanies the first, the patient having alternately each sort of attack, and because when it does exist alone, it invariably degenerates into true epilepsy. In most cases the invasion of a fit of epilepsy takes place without any preliminary warning to the sufferer. Sometimes, however, although the patient is not conscious of the impending evil, it is evident to all those who are present, from his change of manner, from the movement of his eyes and features, and his extreme irascibility. Certain individuals feel the appearance of the epileptic convulsions, the head aches, they see flying sparks, experience hallucinations, or a peculiar sensation starting constantly from one part of the body, and seeming to rush towards the head, where it appears to confuse the ideas and produce the fit. This sensation has been denominated the *aura epileptica*. It is occasionally observed in recent epilepsy, but is by no means a common symptom. Cases are on record in which the fit has been prevented by intersecting the progress of the aura, or by cauterizing or destroying the part from which it proceeded. As the epileptic fits progress, or in other words, when the epilepsy confirms itself, the sensation of the aura gradually wears off, and finally disappears.

At Bicêtre, where most of the cases are

of old standing, I could not find, among above one hundred epileptic, any one who experienced the true aura. Potin Michel, aged 29, complained just before the attack, of a globe rising from the hypogastrium, and arriving rapidly to the larynx through the abdominal and pectoral cavities. At the larynx it stopped, and seemed to suffocate him. He always retained a certain degree of consciousness during the fit. He could hear and see confusedly, but his agony hindered him from answering any questions. Another patient felt also the sensation of a globe or ball, but it was fixed at the epigastrium, and seemed progressively to expand, creating intense anxiety and excruciating torture. The disease in these two men approached to hysteria, and their aura to the globus hystericus. Potin had in his whole appearance something feminine, he was of delicate feature, with soft voice, large breasts, and beardless chin. A few weeks ago I had an opportunity of observing the aura epileptica, in a young man of nervous temperament, aged 22, who, after some bacchanalian and venereal excesses, was seized with fits of epilepsy. One evening, while seated in my surgery, he felt, to use his own expression, the fit creeping gradually upon him, from the fingers of his left upper extremity. When I examined him, the muscles of the forearm, particularly the flexors, were already seized with tetanic rigor. I immediately straightened the fingers, and made him rise from his seat and walk rapidly about the room, striking forcibly the palm of the afflicted hand, the starting point of the aura. By this means the fit was prevented, and has never returned. He had previously been bled and purged; and has since totally renounced his habits of intemperance.

Whatever symptoms precede the arrival of a paroxysm of epilepsy, the phenomena of the fit itself is identical. The patient utters a cry and falls, the body is seized with a tetanic rigor that lasts one or two seconds, and degenerates into convulsions, with alternate contraction and relaxation of the muscles. The actions of the extensors seems however to predominate. Occasionally one limb alone is convulsed, sometimes one side of the body; in a word, there may be as many different movements as there are different combinations of muscular action; but in most cases the whole muscular system is violently and irregularly agitated. During the attack the tongue protrudes from the mouth, and is often bitten and lacerated

from the trismus of the muscles of the jaw; hence the sanguineous froth that issues through the lips, and covers the patient. From the moment of invasion the intellectual faculties are entirely abolished, the patient is insensible to the most powerful stimuli. The action of the heart is considerably increased, the head is thrown back, the face from the embarrassment of the respiratory muscles is turgid and violet, the blood not unfrequently exuding through the integuments of the head. The feces, urine, and sperm may be involuntarily ejected. The attack ends by a long and painful inspiration, in which the sufferer contracts all the muscles that dilate the thorax. These dreadful symptoms are succeeded by a stupid repose. The epileptic is heavy and unintelligible for hours. His features are discomposed, small petechial spots cover his neck and face; they are the result of the rupture of the capillary vessels during the irruption of the blood to the head. This stupor is progressively dissipated, or terminates by a deep lethargic sleep, the duration of which depends on the greater or less fatigue that the system has undergone. The epileptic often complain after their attacks of aching in the limbs, similar to that experienced by persons unaccustomed to muscular exertion who have exerted themselves more than usual. This symptom may remain two or three days, and generally yields to gentle frictions with camphorated liniment. An epileptic fit lasts four or five minutes, and increases in length as the sufferer waxes in years. I have known an attack continue an hour, in defiance of all the remedies that were prodigally employed. In some persons the paroxysms come on, at stated periods, every day, or every other day; but in nine cases out of ten their arrival is very irregular, and seems connected with the state of the atmosphere. The epileptic Gailard, written in 1829, at the Hospice de Bicêtre will remain a month or six weeks without a convulsion; but to my knowledge he has had seventy successive, but distinct, attacks in four-and-twenty hours. During the interval of these series he enjoys the plenitude of health. His intellect is moderately developed, and the disease appears not yet to have preyed upon it. The frequency of epileptic fallings varies much in different subjects. Adam (written in 1829), at Bicêtre, has several paroxysms daily, and never passes a day without one or two attacks.

Every cause of nervous excitement

may produce a convulsive fall in an individual afflicted with epilepsy. Intemperance, unusual exertion, moral emotions, &c., are proximate causes, and according to the statements of all the epileptic patients I have interrogated, and who would answer the question, coition is followed immediately by an attack, and in many, the first fit had been an interruption of venereal pleasure. At the Hospice of Bicêtre, in which the epileptic are assembled in great numbers, masturbation is a very common vice among them. Night is less favourable than day to the epileptic, more paroxysms of the disease occur from midnight to two in the morning than at any other hour. It has been affirmed that epilepsy is more frequently met with in hot than in cold climates; I will not pretend to decide this point, but certain it is, that at Bicêtre more falls occur in summer than in winter. More maniacs also are brought into the public establishments in France in July and August, than in any other time of the year. A sudden variation of temperature, or change in the weather, is constantly accompanied by an increase in the number of epileptic attacks. Never are they so frequent and intense as during a hot stormy night. The nervous system is influenced by the electricity of the heavens, and in the epileptic subject it is more developed, more active, than in another. He is a living barometer. Habit has also a great influence on the repetition of the symptoms, and this is a consideration that should never be lost sight of in the treatment of the malady. During the intervals of the attacks, intervals that are of long duration while the disease is of recent date, the epileptic are often melancholy and deeply affected with the incertitude of their miserable fate. Like all persons of nervous temperament they have acute feelings, and are generally ready to submit themselves to any treatment in the hope of a cure. The depressed spirits of the epileptic does not produce any *penchant* to suicide.

Some individuals never experience but one stroke of epilepsy, which disappears without leaving any functional or organic lesion of the brain. It happens, however, sometimes, that after a single fit the intellect remains weak, and only acquires, by degrees, its original vigour. Memory is always the faculty that is most impaired by this affection. Authors relate that one fit of epilepsy, originating from a sudden and violent terror, has been known to destroy completely all the powers of the

mind, and to reduce to the condition of a drivelling idiot, a man who, but a few moments before enjoyed the range of an extensive capacity. Death itself may be occasioned by the first paroxysm in a subject extremely irritable, and when the proximate cause is excessively violent. But it is rare that the disease terminates thus rapidly; the first convulsions are followed by an interval more or less protracted, during which the patient recovers apparent health, to be soon affected with fresh attacks, augmenting in frequency and intensity as he advances in life. The history of most cases of epilepsy is the following,—the powers of the intelligence are gradually worn out, the interval between the fits becoming shorter and shorter, till it happens that the obscurity of mind consequent upon one attack, is not dissipated at the arrival of another, and the victim falls into permanent idiocy.

Atrophy of the body accompanies that of the mind, a limb, or part of a limb, becomes paralysed; yet, notwithstanding this state of marasmus, the muscles are from time to time dreadfully agitated. Patients will live for years, insensible of their condition, and reckless of every pleasure except that of food, which they continue to the last to devour with voracious appetite. The tragic scene terminates by some organic disease, of the more important viscera, and, strange to relate, an epileptic idiot, in the last moments of his existence, will often show glimmerings of a reason that had been abolished for years. At Bicêtre the epileptic succumb, in summer, to diseases of the intestinal canal, and in winter, pneumonia and the scurvy make great ravages among them.

Dloville affirms that epileptiform vertigo has a more speedy effect on the mind than the true epileptic fit. I have remarked that men of robust constitution *do not* resist the workings of the disease longer and better than those of more meagre and weakly habit. Certain epileptic subjects experience but little inconvenience from their attacks, they are universally persons whose paroxysms come on at very distant periods. The accidental epilepsy of children, eclampsia of the ancients, disappears often after the cutting of the first teeth, and scarcely ever resists the genial influence of puberty. Not so hereditary epilepsy, which always *waxes* in strength as the patient grows older, and accompanies him to the grave. In women there is an exacerbation of the disease at the period of every menstrual dis-

charge. This remark was made by an observer at the Salpêtrière, which is an asylum for females similar to Bicêtre for males. Menstruation irritates the nervous system, and makes it more impressionable. Pregnancy suspends epilepsy; the action set up in the womb, the influx of vital fluid to that part prevents the head from being congested. It is perhaps for this reason that the invasion of an acute disease suspends epileptic fits. The acute phlegmasiæ of the thorax seemed to have more constantly this effect than those of the abdomen. The fits generally (not always) return when the intercurrent disease is cured. It is said that when an intermittant fever seizes an epileptic patient, and is cured by nature or by art, the epilepsy never reappears.

Credat Judæus Apella

Non ego.

On this principle, however, certain practitioners have tried to regulate, by various means, the arrival of paroxysms, and to render them periodical, hoping that a dose of quinine would be an effectual remedy. I am sorry to say that no case is on record in which these efforts succeeded.

If we reflect one moment on the symptoms of epilepsy, we shall not hesitate to declare, that the brain is the seat of the disease; during the paroxysm paralysis of the organs of general and specific sensibility, and cessation of the intellect, while the other function of the encephalon, that of supplying the muscles with nervous power, is enormously superexcited. It is, then, to the nervous centre that we must principally direct our attention in the post mortem examination of the epileptic. The convulsions of children are often confounded with epilepsy; a convulsive fit may be sympathetic, but twice continued epilepsy scarcely ever.

In recent epilepsy, when death has been caused by another malady, it is often impossible, with the most minute inspection, to detect any pathological lesion of the organ of innervation. Many of the encephala examined at Bicêtre, might have been given as models of the sound state. The only palpable alteration I have now and then met with, in the few autopsies of recent epilepsy that came under my observation, was a considerable firmness of the white pulp of the brain. The head of the epileptic is perhaps smaller than in other subjects. In chronic epilepsy almost every lesion of the nervous centre has been observed, tubercles, spiculæ of

bone, fungi, &c. I pass over these because rarely met with, to notice a pathological modification which, although not constant, has often been found at Bicêtre and at la Salpêtrière; I mean the induration of the posterior lobes of the brain. This hardening generally occupies the pes hippocampi and the inferior corner of the lateral ventricle. In two post mortem inspections of chronic epilepsy, made by myself, this lesion was very marked, and in the patient Noël, aged 22, epileptic from his infancy, and who died of acute pleuritis, the posterior lobes of the brain, and the pes hippocampi, were of the consistency of cartilage. From such facts as these, some authors have concluded that epilepsy is an inflammation (chronic of course) of the brain. The perseverance that these gentlemen have displayed in their pathological researches is admirable, certainly, but they have not explained the most important thing in the disease, i.e., the intermittance of the fits. I have, once or twice, found the arachnoid membrane in epilepsy, dotted with small white spots or cartilaginous structure. Let us add, that when the epileptic die during a paroxysm, a considerable degree of cerebral congestion is found. The presence of blood in the encephalon does not explain any of the essential phenomena of epilepsy. The congestion is produced by the morbid action of which the brain is the seat; it is kept up and augmented by the energetic and accelerated contractions of the heart, and by the absence of proper movements of expiration and inspiration, so necessary for the return of venous blood to the centre of circulation.

Epilepsy is a disease often simulated—it may be complicated with almost every other affection, and is frequently concomitant with mania. Epileptic mania is characterised by a furious delirium, with tendency to mischief, destruction, and bloodshed. Epilepsy is undoubtedly an hereditary malady, and may often be traced, lineally, through four or five generations. Like mania, scrofula, and phthisis it is more common among the Jews, and those religious sects whose creed forbids them to intermarry with persons of another persuasion. Under such circumstances, the sphere of connection being limited, vices are more easily propagated by descent. I have interrogated the relations of several epileptic patients, and can assert, without hesitation, that I scarcely ever found true epilepsy in a subject, whose parents or forefathers had not been afflicted with some disease of the nervous

system. When epilepsy is not hereditary it requires a long series of accidental causes to produce the first paroxysm. Moral emotions, excessive anger, joy, or grief are proximate causes of epilepsy, but fright is the most powerful. No impression perturbs so profoundly as terror the functions of the nervous system; and in nearly all of the persons by me interrogated, the first attack was solely ascribed to fright. Causes purely physical may give birth to epilepsy; authors say that it may follow a blow, a fall, or a concussion of the brain.

True epilepsy has sometimes originated in a simulation of the disease, and it is certainly dangerous for irritable persons to view often the fall and convulsions of an epileptic. An Interne at Bicêtre, frequently in the discharge of his office, called to render medical assistance to the epileptic, after three months' sojourn in the hospital, began to experience spasmodic contractions of the muscles of the throat, and other disagreeable sensations. He prudently withdrew from the asylum. It is a custom in France, to mix, indiscriminately in the same ward, the insane and the epileptic. This is essentially pernicious to both. At Bicêtre the epileptic inhabit the same *salles* as the convalescent maniacs—another absurdity. The tender nervous system of a convalescent madman may be singularly shaken by the continual sight of epileptic fits, and I could bring forward one or two cases of epilepsy, developed during the stay of individuals in these, I may say, infected wards.

More women than men are epileptic, and this may be explained by the greater irritability of the nervous system in the female. The epileptic are often of strong constitution, in them the forehead is depressed and covered with hair, the eyes large, the physiognomy dull, the neck short and slightly curved forwards. In those that are young, and who enjoy good health in the intermittance of the disease, the muscular system is well organized, and they are capable of performing very hard labour. This predominance of the muscles has not escaped the notice of Dr. Ferrus. As every muscle acquires strength by exercise, he attributes the anomalous power of the system in the epileptic, to the frequent and powerful contraction of the fleshy fibre during the paroxysms of the disease. Atrophy of the muscles takes place in after life, when the brain has become deeply diseased and the nutrition of the whole body suf-

fers from want of the animating influence of the centre of innervation.

The epileptic are volatile and inconstant, addicted to the pleasures of the table, and to every species of sensuality; although these enjoyments evidently tend to aggravate the disorder. They are in character petulant and boisterous; their anger is a blind fury, knowing no bounds, and in their quarrels I have repeatedly known them strike persons with whom, but a few moments before, they were living in amity. They are differently governed, and most ungrateful for services rendered. The sphere of their intellect being very limited, they possess little memory, and consequently no capacity for study; yet some epileptic subjects are not without *mit* (*esprit de saillie*), and have the repartee and exact and caustic.

Epilepsy is considered incurable by the greater part of the profession. Imbued with this idea, they either do not treat the disease, or employ, empirically a few remedies that scarcely ever fulfil any positive indication. Perhaps it would always be possible to ameliorate the condition of the epileptic, if practitioners gave more attention to the malady, and followed up, with perseverance, a rational and physiological treatment. They should never forget that epilepsy is a disease of the brain, and that all its symptoms are merely accessory to this primary lesion.

I have seen treated by others, and have treated myself, many epileptic subjects, and I may venture to affirm, that the antiphlogistic regimen and treatment, employed with moderation, are the best, and the remedies vaunted as powerful antispasmodics, have little effect whatever in arresting the progress of the malady. General bleeding is the first and most powerful antiphlogistic. It may always be employed with advantage in young and vigorous patients, who are conscious of the approach of the paroxysms. Under such circumstances, venesection performed before the fit, invariably diminishes its intensity. The epileptic, when young, are often plethoric, and bear phlebotomy well, but it should be cautiously employed on those whose convulsions are of ancient date, and whose intellectual powers begin to verge towards demency. In such cases it only hastens the arrival of permanent idiocy, *marasme*, and death. I have sometimes bled patients during the fit, but the convulsions were never diminished from the loss of blood, and often became more intense. The irregular contractions of the muscles

of the upper extremities, render it frequently difficult to stop the hemorrhage from the aperture of the vein. After the fit, bleeding is rarely to be recommended, except when there remains a state of apoplexy, or evident signs of inflammation of the brain or its membranes. It is better to employ external and internal stimulants to dissipate the torpor consequent upon the paroxysm. To the use of general bleeding before the fit may be added, the application of leeches to the temples, behind the ears, in the environs of the arms, or to the genitals of females, in whom the suppression of the menstrual discharge is an accompaniment of epilepsy. Cupping on the scalp has been strongly recommended, and the warm bath, with cold effusions on the head, has been of the greatest service. A seton may be kept constantly open in the nape of the neck; it is a permanent and powerful revulsive. Mons. Gendriu has advised, in epilepsy, cautious cauterization of the synclit, by means of an ammoniacal ointment. The ulceration produced by the application should be as large as half-a-crown, and kept open for some time. This method of treatment has been very much vaunted in the Parisian Hospitals.

To the above-named treatment we may add, light exercise, change of scene, frugal diet, and a moral treatment, for which rules cannot be laid down, as it will necessarily vary with every physician, and according to the character of the person treated. The antiphlogistic is undoubtedly the most *rational* treatment, but it is the very worst when carried to excess, (a common fault in the French schools,) as the abstraction of too much vital fluid, from persons already under the influence of a debilitating disease, is liable to bring on premature marasmus. At Bicêtre were often seen persons who, before their arrival in the establishment, had been the victims of too severe a regimen. They were pale, meagre, and broodless, and their heads and necks were covered with the scars of leech-bites. Bleeding, when too copious, augments, instead of diminishing, the epileptic convulsions. In epilepsy it is better to bleed often, and draw a moderate quantity of blood each time, leaving a certain interval between the venesections, so that the patients may rally sufficiently.

At Bicêtre little faith is placed in antispasmodics, however, musk, lactucarium and valerian deserve a trial, and may be

administered to pallid weak subjects, when the antiphlogistic treatment cannot be persevered in. Prussic acid was once tried at Bicêtre, but the result was unfortunate. It might be a useful remedy in cautious hands.

The French practitioners generally are sparing in the use of cathartics, but Monsieur Ferrus often followed the practice so much vaunted by the ancients in cerebral affections, and added brisk purges to the above named treatment.

It is said that the islands of Antieyra furnished the Romans with the hellebore, so much celebrated for the cure of mania and epilepsy; and Pliny, the elder, relates that Drusus was radically cured of the latter disease by the use of the remedy (*comitali morbo liberatus*). Mons. Ferrus was averse to emetics in diseases of the brain; they always augment, temporarily, the cerebral congestion, and should be cautiously avoided in a disease that almost consists in a sudden impulse of blood to the head. The epilepsy of children, when not hereditary, often disappears under the genial influence of puberty.

It has been said that the nitrate of silver, employed with perseverance, will sometimes effect a radical cure of epilepsy. It is a dangerous remedy and requires to be used with great discrimination, for it may destroy the life of the patient by creating disease of the stomach. The most horrible erosions and ulcerations of this viscus have been found in the bodies of persons to whom this remedy had been long administered. It also changes the colour of the skin to an indestructible olive.

Mercurials and gentle salivation might also be tried with advantage in epilepsy. I do not pretend, in the above pages, to have stated anything new to the profession, but merely to give a correct account of epilepsy, as observed by me at Bicêtre in 1829.

ON THE USE OF IODIDE OF IRON.

By M. RICORD.

The advantageous results obtained by iodide of iron, given internally, in cases where tonics should be combined to antivenereal medication, particularly when

scrofula or lymphatism complicate the affection, entitle this medicament to be classed among the most powerful agents in secondary syphilis.

From the cases collected during the last two years, it may be observed that many patients who had gone through the usual treatment without deriving any benefit, and who had even grown worse, have found iodide of iron greatly modify their constitution, and the morbid cause which prevented the disease having its regular course no longer existing, the cure is speedily effected.

But it is not only to modify the constitution, that M. Ricord recommends iodide of iron; the disorganization resulting from syphilis is removed through the influence of this therapeutical agent. A few days after it had been taken, ulcers on the legs, of so bad a nature as scarcely to leave a hope of cure, have rapidly cicatrized.

The same observations have been made for ulcerations of the throat, which mercurial treatment tended to increase; and we shall here notice this deplorable error of some partizans of ancient doctrines, who fancy themselves obliged to attribute to syphilis all ulcers co-existing, or developed during the course of the disease; while it often happens that the lesion is produced and maintained by the use of two powerful medicines, or pretended specifics, unless they be given up.

In patients affected with diseases of the bones of the skull, the face, tibia, &c. strong doses of iodide of iron have induced the separation of the decayed portion in a much shorter time than by the use of the means generally employed. Indeed, the decay has been arrested before the effects of the therapeutical agent have been noticed.

In scrofulous, lymphatic, and weak patients, the chronic discharge of the urethra and vagina have promptly ceased under the influence of this new medication.

Without alluding to the particular indications which may result from the state of the subject, and the necessity of sometimes combining the administration of iodide of iron with bitters and antiscorbutics, the dose fixed by M. Ricord is six grains, increased gradually every two days, until the result be favourable, and we have sometimes seen as much as forty grains administered in a day.

We shall now show the new manner of applying iodide of iron, which has proved

eminently successful. Administered in injections in cases of *blennorrhagia*; even when the disease is of long standing, and particularly when there is but little pain in the urethra, it will be found a most desirable remedy.

The following cases, taken from the venereal hospital in Paris, will be the best possible proof of the efficacy of this medication.

— Ribaprey, aged 21, was admitted into the hospital the 23rd of December, 1836.

Abundant urethral discharge during two months; no pain in voiding the urine.—*Injections of iodide of iron*: he went away cured the 9th of January.

— Vallier, aged 29, entered the hospital the 6th of January, 1837.

Blennorrhagia, of six months standing; the 7th of January, injections of iodide of iron; the 9th he went away cured.

— Ricauner, 22 years of age, came to the hospital the 6th of January.

Had been effected with *blennorrhagia* for six weeks, epididymitis during the last four days; injections of iodide of iron the 7th of January; compression of the testicles by Vigo's bandages. Cure the 9th of January.

— Faneau, aged 21, admitted the 27th December, 1836.

Blennorrhagia for a fortnight; great pain in making water, Antiphlogistics, and copaiiba unsuccessful till the 13th of January; iodide of iron; cured the 16th of January.

Jean Ville, aged 25, came to the hospital the 6th of January, 1837.

Blennorrhagia, during five months, have resisted every treatment; copious discharge; the 7th of January injections of iodide of iron; cure the 10th of January.

— Vives, aged 29, entered the 3rd of January, 1837.

Blennorrhagia, of eight months standing; 4th of January, injections of iodide of iron; left the 7th, cured.

Nearly all the cases are the same, and the duration of the treatment is also the same.

It is essential to observe, that iodide of iron is administered in doses of half a drachm in eight ounces of water; in one single case excepted, when two drachms in eight ounces of water were prescribed. M. Ricord employs the first formula, and seldom goes beyond the second; yet there are cases necessitating a drachm of iodide of iron to an ounce of water. However

this may be, the treatment is very active, and requires to be administered with great judgment; for besides the difficulties resulting from therapeutical indications, the intensity of its action appears to vary considerably, according to the quality of iodide, and for certain doses, whether the solution be filtered or not.

In all cases of blennorrhagy, where astringent injections are indicated, iodide of iron appears to hold the first place. In general, its use is only contra-indicated by great inflammation, or pain in voiding the urine. It is, of course, understood, that all symptoms of cystitis are in the same condition.

With the exception of these circumstances, easily ascertained, complete success may be looked for, unless there be serious alteration of the canal, which in every case would require peculiar concomitant medication.

M. Ricord has remarked in the numerous patients undergoing this new treatment, that when the blennorrhagy was but slight, if there only existed a little urethral heat, and no pain, which pain would have been a contra-indication; iodide of iron administered in doses of three grains to an ounce of water, has put an end to the disease at the sixth or eighth injection.

In very few cases has it been necessary to increase the dose, which should always be done with the greatest precaution, lest as we have already stated, the results should be dangerous. Indeed it may be asserted that without being used to administer iodide of iron, it would be most injudicious to prescribe large doses.

Thus, for two individuals, apparently in the same morbid condition, the injections of iodide of iron may produce effects completely opposite.

In one case the disease disappears as if by magic; we have given several examples of this kind. In the other case it increases rapidly, and may terminate in retention of urine, inflammation of the neck of the bladder, and of the organ itself.

Nevertheless, it must be remembered, that in certain cases we must not be wholly guided by these symptoms. If the use of this medication be suspended, and after two or three days repose, and suitable treatment, all symptoms disappear, the discharge, which in certain individuals was considerable, and tinged with blood, is soon transformed into a transparent secretion, which ceases without further remedy being necessary.

The above symptoms are uncommon,

but would be undoubtedly produced by too great a dose of iodide being given at the commencement of the disease.

The cure is mostly obtained without pain, the patient merely feels a sort of pressure and heat in the canal. Some have pains in the urinary meatus, others suffer when voiding the urine, and by degrees all the inconveniences above-mentioned may take place.

Blennorrhagy having become chronic, whatever may be its source, as we have already observed, when the canal is not deeply altered, has given way to iodide of iron, in four, six, or eight days. In this case, the administration of the medication is to be less dreaded; the canal is less susceptible of sudden inflammation, particularly if the dose of iodide of iron be administered according to the recipe we have given; it is essential to observe that it would be often useless to attempt by local means the cure of an affection receiving all its influence from idiosyncrasy, which could only become better as the whole constitution of the individual improved.

It is because these conditions have not been appreciated, that therapeutic has often appeared to afford such striking diversity. There is no panacea; there are good medicaments, suited too peculiar cases, but which cannot always suffice and be adapted for every circumstance and their combination with other ingredients, may bring on results, that would have been vainly sought by using these medicaments exclusively.

The doses generally prescribed are three grains of iodide to an ounce of water. If the discharge diminishes, the same dose is continued till the cure be complete.

When the discharge does not appear modified, either in its nature or quantity, after two days injections, the dose must be increased by fractions.

If any symptoms of excitement or pain arise, and the medicament is suspended for two or three days, or more, if it be necessary to ascertain whether the continued discharge does not proceed from the powerful action of the iodide.

The patients often feel considerable pains in the urinary meatus, there is a swelling and irritation, but the consequences are not likely to be serious, unless the medication be continued.

We deem it useless to renew the discussions of several authors, who consider injections as producing coarctations of the urethra; we have never found this the

case, and we think that strictures of the urethra may be attributed to the cicatrix of the divers ulcerations of which this canal is the seat, or to the other pathological alterations resulting from the continued inflammation of the mucous membrane.

The London Medical

AND

Surgical Journal.

Saturday, July 8th, 1837.

ROYAL INSTITUTION.

FULLERIAN PROFESSORSHIP.

Three years have now elapsed since the endowment of this Professorship by, as he was familiarly and truly designated, *honest* JACK FULLER.

The demise of this eccentric senator, placed at the disposal of the Managers of the Royal Institution a sum of money out of which was to be paid, by the will of the testator, one hundred pounds annually to some competent person for the delivery of twelve lectures on Human Physiology, and, with that extraordinary tact and ability for which Dr. Peter Mark Roget has ever been remarkable, Mr. Fuller was induced not only to order that the Doctor should be appointed to the professorship, but was also prevailed upon to continue it and its emoluments in his possession for three years certain. In justice, however, to Mr. Fuller, it is but right to state, that many overtures were made to him to continue the professorship for life to Doctor Roget; and it was probably owing to the repeated applications of this kind, that he was induced even to desire that it should be a triennial appointment.

Agreeably, however, to the will of Mr. Fuller, the Professorship of Physiology to the Royal Institution became vacant a few weeks since, and the following individuals, amongst numerous other candi-

dates, immediately laid their pretensions to perform its duties before the Managing Committee,—Doctors, Grant, Sigmond, Trueman, and Todd, and Messrs. Owen, Solly, Mayo, Howship and Partridge. It was not for a moment contemplated, after the great dissatisfaction universally expressed by the patient hearers of the physiological orations of the late professor, that Dr. Roget would have had the temerity to again offer himself as a candidate; yet, strange as it may appear, the ex-professor was the first in the field; but soon finding that all chance of enjoying the sinecure was at an end, an attempt was then made to prove that it was the intention of Mr. Fuller to continue the Professorship to Dr. Roget for life. Even this new interpretation of the intentions of *honest* JACK FULLER, failing to convince the Managers, they were at length relieved from the imperative but painful duty of declaring themselves determined to dispense with the services of the late professor, by his retirement.

The proposal of Dr. Trueman to deliver a probationary lecture, in proof of his abilities to fill the vacant chair, met with as little success as the tact of Dr. Roget; and, with the exception of Dr. Grant and Mr. Owen, the Managers dealt with the pretensions of the other candidates as unceremoniously.

Had the professorship being endowed for the purpose of giving a short course of lectures on Comparative Anatomy or Zoology, no choice could have been left in selecting from the list of candidates Dr. Grant and Mr. Owen; but it was rather a foolish proceeding, and certainly not carrying the intentions of the testator into effect, to select these two gentlemen to deliver twelve lectures on HUMAN PHYSIOLOGY, because they happen to have gained a just reputation as Comparative Anatomists.

It would not have been a bit more absurd, had they selected Mr. Partridge, because his excellence is known as a mere demonstrator of human anatomy, or Doctor Todd, because he is the editor of the *Cyclopædia of Anatomy and Physiology*. In the absence of evidence as to the physiological abilities of the several candidates, we do think that the Committee of Managers of the Royal Institution, erred greatly when they did not accede to the honest and bold proposition of Dr. True-man; particularly as their selection of Mr. Owen to fill the Fullerian professorship, was decided by a similar test; a few of the acting Managers having spared an hour from their mercantile pursuits to test his merits, by attending one or two of the lectures lately delivered by him at the College of Surgeons, on Comparative Anatomy.

Mr. Owen, we understand, will be spared the necessity of endeavouring to carry into effect the desires of Mr. Fuller, in consequence of the *liberal* individuals of the Council of the College of Surgeons having signified their desire that Mr. Owen should devote his sole labour in their service, for which they conceive *three hundred per annum* a very handsome remuneration!

That the liberal individuals of the Joint Stock Company of Gower-street, will, in all probability, lay a similar embargo on their Professor of Comparative Anatomy, is highly probable; for so justly fearful have the medical staff of this *enlightened* institution been, lest their emoluments might be lessened by competition, or their abilities suffer by comparison, that some of their professors are bound in a deed, not to lecture within a certain distance of University College and the North London Hospital; a proceeding only to be equalled by those high-minded practitioners, who, when engag-

ing an assistant at thirty or forty pounds a year, compel him to sign a paper, not to practice within *twenty miles* of the establishment!

The objections we have raised against Mr. Owen's appointment, apply equally to Dr. Grant. This *great* man, who justly merits this appellation for his talents as *Comparative Anatomist and Zoologist*, may give very little satisfaction as a professor of *Human Physiology*. We trust, therefore, the Managers of the Royal Institution will not be led away by their having heard a few popular lectures, on a subject widely different from the one for the proper execution of which they are now called upon to select the ablest individual.

Comparative Anatomy and Comparative Physiology are of the highest importance as scientific pursuits, but to the Human Anatomist and Human Physiologist, the beautiful truths of the former sciences are only of value in the light they shed, in unveiling the intimate structure of our several organs, and the uses that an all-creating being has destined them to perform in our economy. It is for the elucidation of these truths, that the Fullerian professorship was endowed; and the Managers, who have the selection of a fit and proper professor, will do well not to lose sight of this object in their choice.

THE ANATOMIST.

Tuberculum Lomeri, an eminence upon the under surface of the sinus of the auricle and placed between the orifices of entrance of the venæ cavæ.

Septum auricularum, a membranous muscular partition separating this auricle from the left.

Fossa Ovalis, an oval depression in the septum, which marks the situation of the foramen ovale, or the oval communication which existed between both auricles in the fœtus. The edges of this fossa

present a thickened margin, the anterior part of which is named the left or anterior limbus of the fossa ovalis, and the posterior, the right or posterior limbus. This fossa and its limbi exist in the right aspect of the septum on account of the valve in the fœtus, which is destined to close the opening between the two auricles when the pulmonic circulation is established, being situated in the left auricle and being applied to the foramen on its left aspect. We accordingly find the left aspect of the septum auricularum perfectly smooth.

Valvula Nobilis or *Eustachian valve*, a semilunar fold of the lining membrane attached by one cornu to the anterior limbus of the fossa ovalis, and continued around the anterior aspect of the inferior vena cava, to reach the posterior limbus of the fossa ovalis, to which it is attached by its inferior cornu.

Musculi Pectinati, the muscular bands situated in the auricular appendix.

Openings of the Venæ Cavae. The superior cava opens at the upper and back part of the auricle, its direction being downwards, forwards, and inwards; the inferior cava opens beneath, in a direction upwards, backwards, and inwards.

Opening of the Coronary Vein is situated between the Eustachian valve and the right ventricle, and is guarded by a semilunar valve (the valve of the coronary vein.)

Opening of the Auricular Appendix, is small and circular, and exists where this portion of the auricle joins the sinus.

Foramina Thesebii, small orifices on different parts of the auricle, supposed to be the openings of veins.

Right Auriculo-ventricular opening, the large opening by which the auricle communicates with the ventricle, the boundaries of each cavity being marked by a white line.

Right Ventricle, of a conic form is joined by its basis to the right auricle, its apex being above the apex of the heart, in consequence of the apex of this organ being formed by the left ventricle.

Septum Ventriculorum, a thick muscular partition which separates one ventricle from the other.

Carneæ Columnæ, the muscular projections in the interior of the ventricle, which give it its irregular appearance.

Chordæ tendineæ, the delicate but strong tendinous cords which are connected by one extremity to the carneæ

columnæ, and by the other to the tricuspid valve.

Tricuspid Valve, three triangular duplicatures of the lining membrane of the heart, strengthened by the chordæ tendineæ which pass from their apices to their bases. These triangular valves are attached by their bases to the right auriculo-ventricular opening, and by their apices to the chordæ tendineæ, and prevent the regurgitation of the blood from the ventricle into the auricle by closing the opening of communication between both cavities when the ventricle contracts.

Orifice of the Pulmonary Artery is situated at the left extremity of the vasa of the ventricle, close to the right auriculo-ventricular opening, which is situated inferior, posterior end to its right, and separated from the mouth of the artery by the largest triangular division of the tricuspid valve.

Pars Planum is a name given to that smooth portion of the ventricle, which leads to the mouth of the pulmonary artery.

Pulmonic Semilunar Valves extend from the line of junction of the pulmonary artery and right ventricle into the cavity of the former. These three valves are duplicatures of the lining membrane, and are attached by their convex edges to the roots of the pulmonary artery; their free concave margins presenting in their centre a small tubercle, called *corpus sesamoides*. These valves, when the blood passes from this ventricle into the pulmonary artery, are thrown down, and thus, by closing the opening, prevent a reflux of the blood back again into the ventricle.

Left Auricle is placed at the upper and back part of the heart, and is of a quadrilateral form. It is smaller than the right auricle, and receives, at its four angles, the opening of the pulmonary veins; its parietes are much thicker than the right; its auricular appendix smaller, but the musculi pectinati are the stronger; with the exception of the auricular appendix its inner surface is smooth, and it communicates with its corresponding ventricle by the left auriculo-ventricular opening, which is situated inferior to the opening of the auricular appendix, and marked by a whiteish line. The septum auricularum presents towards this auricle a smooth aspect, from circumstances already explained.

Left Ventricle is longer, stronger, and smaller than the right; from its greater length it forms the apex of this heart; from its greater strength it is of power suffici-

ent to propel the arterial blood through the aorta and its ramifications. We consequently find the *carnea columnæ*, the *chordæ tendinæ*, the *bicuspid*, or mitral valve, the *parietes* of the cavity, the aorta, which arises from it, and the semilunar valves, with their *corpora sesamoidea*, which guard the opening of this vessel, much stronger than in the right division of the heart.

The left auricular-ventricular opening, and the mouth of the aorta, are situated at the base of this cavity, and are close to each other, the aortic opening being anterior, and both being separated, as in the right ventricle, by the larger division of the *bicuspid* valve. With the exception of the peculiarities just mentioned, the left auricle and ventricle are, in their anatomical configuration, similar to the right, and the several valves, muscular eminences, tendons, cords, &c. serve similar purposes.

THE COLLEGE OF SURGEONS AS IT IS AND AS IT OUGHT TO BE.

*To the Editor of the London Medical
and Surgical Journal.*

SIR,—Having read in the last number of your very excellent and liberal journal, some few remarks on “Mr. Owen and the College of Surgeons,” I cannot, as a member of that body, refrain from offering you my individual thanks for the interest you have shown not only on this but on a thousand past occasions, to promote our welfare and expose the machinations of an official body, constituted on the most illiberal principles. A body calculated not only to make every member feel disgusted at being connected with it, but also to check that ardour for discovery and improvement in the healing art which would necessarily follow from a more liberal system.

I should not hazard these assertions did I not feel convinced that every surgeon entertained the same opinions as myself, although from a variety of causes he may neglect to publish them, and this neglect is undoubtedly looked upon with a great deal too much indifference: for, how can slaves break through their chains by quietly smiling on their captivity? how can a wretched people borne down by political oppression free themselves from its thralldom by timidity, inactivity,

and cowardice? or how can the members of the London College of Surgeons raise themselves to that dignified station which their education demands, by tranquilly speculating on what they might have been, or might still be, where they governed by individuals who studied *alone* their interest—who were willing *alone* to administer to their benefit and respectability?—No Sir, it is not by following this system of creeping quietly on unheard, and consequently unthought of, that we may expect our wrongs redressed—it is not by this torpor and apathy that we may hope to find more beneficial and salutary regulations substituted for the unwarrantable ones at present existing; but it is by raising our voices simultaneously that the thunder may reach to the hidden and mysterious recesses of the council chambers and strike on the ears of those so long deaf to the language of justice, that we may expect to convince them we view their proceedings with aversion and contempt, as being unjust, disgraceful, and calculated to lower us in the estimation of our professional brethren, who possess the diplomas of other more liberal institutions.

No person will be inclined to disagree with me in admitting that *some few* of the council deserve our admiration on account of their superior professional attainments; nor if their honesty and sense of duty had been equal to their talent, would any one have objected to their filling the responsible situations which they now do; but we should not permit our admiration for the acquirements of any individual (howsoever brilliant they may be) to blind us to the melancholy fact that they are oftentimes accompanied by a base desire on the part of the possessor to raise himself by degrading his professional brethren. But I would more particularly speak of another class of beings who form part of the council;—men who have no redeeming point to justify their being placed in the position they now occupy;—men who have no claim to our respect either from their abilities as surgeons or their labours in science;—men who possess not one spark of intellectual fire beyond the commonality; and are alike unknown to the profession and the world: in short, whose only recommendation to such an office is a mean and servile spirit, which bends to every measure advanced by their more crafty colleagues to sacrifice the independence of the only legitimate owners of the college.

These then are the men who assist in

framing every act of *corruption* which emanates from that *pre-eminently corrupt* association of Lincoln's Inn.

Now, were these posts (as they ought to be) held forth as the just reward of exalted genius and professional talent, what honest emulation would spring up in the breast of every surgeon, stimulating him to that ardent research which is so necessary to the advancement of a liberal profession; and giving him energy to grapple with, and strength to overcome the innumerable obstacles that prevent themselves in the arduous and difficult task of discovering truth from error. With what pride should we look back after having paid this tribute to real merit, and say, those are the men who in exalting themselves exalted us and laid the foundation of a liberal and philosophical independence.

I have honour to be
SIR, your admirer,
and your obedient, servant,
MEPHISTOPHILES.

ZOOLOGICAL SOCIETY.

This society held its ordinary scientific meeting on the 27th of June, Thomas Bell, Esq., F.R.S., Professor of Zoology, King's College, in the Chair.

Mr. Gray, of the British Museum, exhibited two specimens of a small species of Fox, from India, apparently allied to *Canis Bengalensis*, if not identical with that species, for the purpose of pointing out the existence of a peculiar gland in the tail, which had hitherto escaped the observation of Naturalists; but which he conceived would form a valuable specific character to distinguish this from the rest of its congeners. The gland in question is found on the upper surface of the tail, about a couple of inches from the root of that organ, and its position is marked by a tuft of coarse dark-brown hair, strongly contrasted, both in colour and quality, with the light-dun woolly fur which covers the surrounding parts. It was this contrast that first attracted Mr. Gray's notice. The Chairman having called upon Mr. Ogilby for any observations he might have to make upon the subject of the structure pointed out by Mr. Gray, that gentleman stated, that from the very slight examination which he had been able to give the subject during Mr. Gray's observations, he was unable to perceive any dis-

tinct gland, but that the quality and colour of the hair indicated, notwithstanding, the existence of a sebaceous secretion. He remarks further, that such characters were seldom or never confined to individual species; that the structure in question, however difficult it might be to assign its juncture, would be found, in all probability, to extend to the rest of the foxes; and that the long dark hair which forms the brush of the common species, may have been the only cause of preventing its earlier detection. Dr. Smith agreed in this view of the subject, and observed that the dark spots pointed out by Mr. Gray existed on the tails of two of the South African species, in the same position which they occupied in the Indian specimens exhibited to the society, and no doubt concealed sebaceous glands of the same description. Mr. Gray next exhibited a new species of large cat from India, remarkable for the great length and thickness of the tail, and intermediate in many of its characters, between the *Felis Macrocelis* and *Felis Iubata*, or Hunting Leopard.

Mr. Ogilby afterwards characterised a new species of Gibbon (*Hylobates*), which had been presented to the society many years ago, by the late General Hardwicke, and hitherto considered as the female of the Hoolock. A specimen of the latter species had been presented to the society at the same time, and from the same locality; but their specific identity was sufficiently disproved, not only by the fact of both specimens being of the same sex, and from being perfectly acquainted with both sexes of the Hoolock, but likewise by the marked difference of colour and external structure exhibited by the two animals. The greater height of the forehead and prominence of the nose in the new species, were pointed out as alone sufficient to distinguish it from all the other Gibbons; whilst its ashy-brown colour and large black whiskers rendered it almost impossible to confound it with the Hoolock, which has fur of a shining black, and a pure white band across the forehead. Mr. Ogilby observes, that we have had two distinct instances of real Apes from the continental parts of India; and referred to various passages of Pliny, in which the Roman Naturalist professed to describe different races of human beings from the remote provinces of India, whom he relates to have teeth like dogs, to live among trees, and converse by frightful dreams. These distorted accounts Mr.

Ogilby conceives to have been founded upon the vague tales brought back by the few Greek and Roman travellers, who, at that time, penetrated beyond the Ganges; and proposed therefore to call the new Gibbon by the name of *Hylobates Choro-mandus*, the name of one of the supposed tribes of men described by Pliny. The same gentleman afterwards exhibited and described the skin of a new species of Colobus, or four-fingered monkey from Africa, for which he proposed the specific name of *Colobus Leucomeros*, on account of the white colour of the thighs, the rest of the animal being a deep shining black.

Dr. Andrew Smith, whose recent arrival from the Cape of Good Hope with the most extensive and valuable collection of objects of Natural History, dresses, arms, and other articles connected with the native tribes of South Africa, perhaps ever brought into this country by a single individual, next exhibited and described four or five different species of the genus *Macroscelides*, or the Elephant Shrews, collected during his late interesting journey to the interior. Dr. Smith himself had originally characterized this curious genus in the *Zoological Journal* ten years ago, yet it has been recently reproduced under a different name, by Professor Lichtenstein, of Berlin. Dr. Smith gave some valuable details with regard to the habits of these animals, as likewise of four different species of *Chloromys*, which were likewise exhibited, out of which two at least were new to Science. We cannot conclude this report without congratulating the public, and more especially the scientific portion of it, upon the approaching exhibition of this gentleman's valuable and interesting collection at the Egyptian Hall. The exhibition will be found well deserving of repeated visits from every person interested in the productions of Africa, or the manners and customs of the Caffres, Zoolas, Matlapées, Bichuanas, and other tribes, whose late intestine wars have made them known to the public, or whose progressive improvement, under the care of the missionaries, is more silently watched by the philanthropist. Let it be understood that the exhibition is not for private emolument, it belongs to the South African Literary and Scientific Association, and is intended to enable that valuable and enterprising body to fit out a second expedition to the interior of that interesting Continent. May success attend their efforts!

ON THE APPLICATION OF SOLID NITRAS ARGENTI IN THE GONORRHOEA OF WOMEN.

By ALEX. J. HANNEY, M.D.

Gonorrhœa in the female is commonly said to be a very curable disease. It is certainly much more so than in the male; but on practical investigation of this disease, I found that it was not so curable as has been supposed—at least by the means commonly used. I tried every form and combination of astringents, particularly that of zinc; half an ounce of each in a pound of boiling water was my common injection. This occasionally effected a cure in eight or ten days; but for one case in which this took place in the time specified, ten resisted the treatment for three or four weeks. The records of Lock Hospitals bear this out to the full; and cases so treated often returned on leaving off the remedy. I had no better success from the solutions of the nitrate of silver; they were indeed, generally less effectual than the other; besides the method of injection is apt to be so irregularly pursued by the thoughtless characters in Lock Hospitals, that it will seldom be carried into complete and proper execution. It is a common boast of such persons how little they have regarded the injunction of the practitioner in this particular. I know one case where a woman used the alum and zinc injection just twice in nineteen days, whilst the practitioner fancied she was using it three or four times daily. It becomes of importance—of the utmost importance—that the treatment in case of Lock Hospitals be of such a kind as that the practitioner can either administer it himself, or be assured that it be done. The remedy to be noticed has this great merit; and if it had not half the efficacy which I know it to have, it would surpass all others on that account in the institution above-named. I had long tried in vain, and I repeat, had found very useless, the injections of an astringent kind.

Having noticed that some cases of gonorrhœa, with ulceration in the vagina, and to which I had freely applied the nitras argenti, stopped in a most extraordinarily short period, I determined to select a few cases of uncomplicated gonorrhœa for trial. I accordingly did so, and found the effects to be very striking. I have repeatedly seen the discharge cease, never

to return, in twenty-four hours. On the day after the application, I have often seen it changed in character, that is, loses its purulent form, and disappear in twenty-four hours more. The discharge changes from the purulent to a thinner, clearer fluid, and ceases, I say in twenty-four hours thereafter, simply by using a weak solution of acet. plumbi., or only tepid water, as a wash. I have kept such cases repeatedly under my eye for a month, and can declare, that in the proportion of 95 to 100, there was no return of the discharge; yet no remedy had been employed after the nitrate. Though in some few cases there is a little pain produced, yet in by far the greatest number of instances, no pain is experienced from the introduction and most free application of the caustic. It is painful, it is true, when it touches sores on the labia, or more internal parts, but that smarting soon goes off, or, at all events, an anodyne instantly relieves it. In the greater number of cases it produces no phlogosis of the parts with which it comes in contact; but in some (say in one case in twenty) it does irritate to a degree that proves painful for a few hours, but never, in any one instance, have I seen the pain continue longer than a few hours. I have never seen bubo induced by it. I have used it in patients in every month of pregnancy with the best effects, and never saw abortion produced. I know, by as careful examination as I could make, that it does not suppress the catamenia: in short, I fearlessly give it out as an infallible and safe remedy for this disease, without any one drawback but the vain fears of persons of no experience, or of such as are determined to oppose it. I have now employed it in above 300 cases with unvarying success, and shall continue to use it.

I am the more particular in the notice of the above groundless evils and vain fears, since I have heard them repeatedly stated as likely to be overwhelming objections against the practice—but only by persons, I must say, who have never seen the method practised. I know, on the most ample experience, that these objections are without any foundation whatever. I am at all times very unwilling to come forward with my remarks before the public, but I have no alternative; I must now speak out for myself, as I understand the treatment has been freely canvassed in the Glasgow Medical Society, where the inexperienced, on the strength of some eight or ten cases, attempted to demolish

the careful observations (conducted before persons of competent judgment, and whose certificates are appended) of several years, and on hundreds of cases. I had the honour of introducing the practice into the Dublin Lock Hospital in August last, and I hope we shall be favoured with a report from that extensive and well-conducted institution. I may add, that in about six cases only, out of more than three hundred, the vaginal discharge has continued after repeated applications: in all of these I found, by the use of the speculum vaginæ, that there was ulceration of the lining membrane of the vagina, and that the case was not gonorrhœa.

The application of the nitrate was not required more than once in 280 of the 300 cases. I may also add, that in two obstinate cases, I found the disease to be kept up from *urethral discharge*, whilst that from the vagina had ceased. I then applied the nitrate to the urethra, and a cure was accomplished in both instances,—in one by a single introduction of the pencil, and in the other it required to be once repeated, at an interval of four days.

So far from the catamenia being suppressed by it, I have known more instances than one of the catamenia flowing for the first time after a long obstruction, on the use of the nitrate. I am so conscious of the benefit and complete success of the remedy in question, that I commit it to the profession, to whom I should not venture to make statements so confidently, unless I believed myself standing on pretty sure grounds.

I shall conclude by describing my method of using it. I introduce a stick of nitrate of silver into a quill, and tie a thread firmly round the lower part of the quill to fasten the caustic, which I leave projecting beyond the quill about half an inch. I generally smear the quill with a little lard, and introduce the nitras argenti up to the os tincæ, or as far as it can be made to ascend in the vagina. I then deliberately and slowly withdraw it, turning it round so as to bring it in as extensive contact as possible with the lining membrane of the vagina. I may add, that by accident, the nitrate of silver has more than once broken in the vagina, and could not be found. It caused me much alarm and anxiety at first, but after the following case I was not so affected; and though I would carefully avoid it, I now regard the occurrence as of very little importance.

The late Mr. John Hebertson, who acted as my assistant in the hospital, came

in breathless haste, and in the utmost state of alarm, to call me to his assistance to extract a piece of nitrate of silver from the vagina of a woman, who having previously been in the hospital, and cured by the use of the remedy in question, came to Mr. H. to have it again applied. On repairing to the house, we searched in vain for the caustic, but had abundant proofs that it had dissolved in the vagina. The quantity he asserted to be above two drachms. She suffered little or no pain, and a perfect cure was straightway accomplished.—*Medical Gazette.*

INJURIOUS DILATATION OF THE OS TINCÆ.

By Dr. E. W. MURPHY.

If the nature of the uterine structure, consisting of muscular and fibro-elastic tissues, be considered; if their properties be borne in mind, and we contrast the action of sphincter muscles generally with the manner in which the os tincæ is opened, namely, by a slow painful dilatation, aided by a fluid pressure, and compare it with the subsequent dilatation of the perinæum, the dilatation of the os tincæ must be considered to be, in a great degree, a mechanical effect; the resistance arises from the reaction of the fibro-elastic tissue, and not from the contractions of muscular fibre; nevertheless, irritation may excite their action, and thus present an impediment to the natural action of the uterus, retarding dilatation, and rendering it essential, consequently, in order to avoid such an effect, to refrain from rupturing the membranes. The os tincæ bears irritation very badly, and if much exposed to it, will certainly manifest a sub-inflammation, which at first retards its distension, and if suffered to increase will soon affect the general system. Daily observation during my residence at the *Lying-in Hospital*, Dublin, has forced this opinion upon me. The natural anxiety of those who were attending the patients, to watch the progress of parturition, gave rise to frequent examinations per vaginam, and the effects of such irritation has been to excite the above-mentioned tendency, manifested by a suppression of the usual mucous discharge, by heat and tenderness, and a tumid, painful, unyielding condition of the os tincæ; and especial caution was necessary to prevent such frequent examina-

tions. The long continued irritation of the head would produce a nearly similar effect. Patients have been sent into the hospital where these symptoms were unnoted. The tenderness and swelling increased; a serious irritating discharge was in the vagina; the os uteri was perfectly rigid, and the muscular action of the uterus and bladder was suspended; urine accumulated in the one, and in the other the true pains were changed for distressing spasms. Thus, a case in which there was no real difficulty was converted into one of considerable risk.—*Dublin Medical Journal.*

NITRO-MURIATIC ACID BATH.

By Dr. LENDRICK.

The nitro muriatic acid is now unjustly described as of little use. Those, however, who decry it had contented themselves with a partial application of the acid to the lower extremities. Many years ago I accidentally recommended it as a *general* bath, and the effects were so surprising that I have never prescribed it in any other form since. Several cases in which it had been used ineffectually in the common way have come under my care, and complete success has followed total immersion in the acidulated water. The patient is placed in a common bath, at a temperature of from 90 degrees to 95 degrees, twice or thrice in a week, for 15 or 20 minutes. Into each bath of 30 or 40 gallons is poured from an ounce and a half to two ounces of concentrated nitric, and from two to three ounces of muriatic acid; the proportion being nearly that of 2 to 3. This bath may be continued for months, not producing either any derangement of the general health, ptyalism, or eruptions as described by some authors, though, as idiosyncracies will occasionally occur, its application ought always to be superintended by a medical practitioner. My own opinion is, that it is admirably calculated in most diseases to produce the beneficial, without the risk of the injurious, effects of mercury. There is a disease known to the public by the name of *liver consumption*. It generally occurs in scrofulous habits, and is probably connected with tubercular growth in that viscus, as well as with the commencement of pulmonary phthisis. Together with the general derangement of the biliary and digestive functions,

there are frequently developed in females, hysteria, with chlorosis, or morbid menstrual secretion. In such cases I have never found any treatment so effectual as the nitro-muriatic acid bath. The hepatic, and even the pulmonary symptoms, seem to yield, and the patient regains flesh and strength. I do not, in all the cases, rely on the bath exclusively; but in some, which had baffled every other treatment, the bath alone seemed to accomplish a cure. Even where mercury had proved injurious, the bath seemed to accomplish all that could be expected. Every addition to our stock of non-mercurial, or anti-mercurial remedies is valuable. The merits of sarsaparilla, nitrous acid, chlorine, &c., and especially (as judiciously recommended by Dr. Wallace) the hydriodate of potash, are well known. I consider, however, the nitro-muriatic acid bath as inferior to none, and superior to many; and being an external application, it in no way interferes with the administration of the others.—*Dublin Journal*.

GLANDERS IN MAN.

By ANDREW BROWN, Esq. Surgeon 2nd Dragoon Guards.

I am not yet acquainted with any case but the following, where glanders has been communicated to man by other means than through incised or lacerated wounds, that is to say, either by cutaneous absorption, by effluvium, or by the incautious application of glandered matter to the nasal linings, in picking, scratching, or blowing that organ:—Corporal John Wells, aged 38, a tall, healthy looking man, nineteen years in the corps, and never before on the doctor's list, on the 16th of April last, was suddenly awakened from an unrefreshing sleep by rigors, headache, and irritability of stomach. In hospital (at Cahir Barracks, Ireland,) next morning he complained, in addition, of severe continued pains, and stiffness of all his large joints, excessively aggravated on the slightest motion. These are the constant precursors of fatal acute glanders and farcy in the horse. On inquiry, it appeared that he had sole charge of a glandered horse for some time previous, which had been destroyed on the evening of his attack; and that he had exerted himself much in cutting up the carcass. But these circumstances not creating the least

suspicion, his complaint was considered to be severe acute rheumatism. However, two days after admission, finding that his constitution was no longer able to bear the very active treatment employed, Dr. Home and myself became truly alarmed at the unconquerable violence and novelty of the disease.

The pain, night and day, became excessive, particularly over the left shoulder, where the scapula was slightly tumefied, although not inflamed; leeches, applied over its entire surface, bled profusely, for some hours, without relief, his sufferings continued unabated; on the 24th the tumour had a dark livid colour, and was so large as to resemble the shoulder of a man recently and severely punished.

Similar tumefactions, but more circumscribed, were now observed on the legs, arms, and sacrum, and one, over the left temple, distorted the entire face. The right nostril was contracted, and gummed with an inspissated discharge; and he complained of constriction of the throat, with difficulty in swallowing cold liquors, but not warm; the posterior fauces were much inflamed, and of nearly a purple hue. The suffering now baffled every effort to procure rest; not even whilst in the warm bath had he a moment's respite from pain. His thirst was great. His excretions, urinary and alvine, were kept natural in every respect. On the 28th several pustules were observed, resembling yaws, particularly over the neck and shoulders, and inside the arms and thighs. Several of the tumours now were running rapidly into gangrene, wholly unimpeded by tonics and antiseptics; nature was at length exhausted, his countenance frightfully haggard and livid, his entire surface bathed in a cold clammy sweat, and of a pale leaden hue. He held out, in partial somnolency and low muttering delirium until the 30th, when death released him from his misery, having been twelve days under treatment.

Autopsy, eighteen hours after death.—The entire surface nearly covered by black gangrenous tumours, each surrounded by numerous small vesications, which, on cutting into them, were found to be merely elevations of the cuticle, filled with a dark, violet-coloured, inspissated lymph. A suspicion having been recently entertained that this disease had its origin in glanders, the absorbents of each arm were first minutely examined, to their termination in the axillary glands. Those vessels, however, as well as the glands, were found in their natural state; nor

was there the slightest appearance of either absorbent, glandular, or cutaneous inflammation, or of any recent cicatrices, chopped or scratched fingers; or, in short, the slightest breach of integument, or abrasion of skin, by which absorption of morbid matter into the system could have been facilitated.

On removing the scalp, and thereby dividing the tumour already specified, we observed, immediately over the left superciliary ridge, a cluster of tuberculated bodies of various sizes, imbedded in a lamina of the cellular tissue exterior to the pericranium, and our highly-talented veterinary surgeon, Mr. Woodman, unhesitatingly recognized a strong resemblance between *these* and *those* usually found in the nasal linings of glandered horses after death.

The brain was much more pale and soft than ordinary, with rather a larger proportion of fluid in the ventricles; the Schneiderian membrane appeared throughout pale, thickened, and infiltrated; and in the right frontal sinus was found another cluster of well-defined, ulcerated, glanderous tubercles. The posterior fauces were highly inflamed, and of a dark purple; right tonsil, ulcerated in patches, but the thoracic and abdominal viscera were all perfectly healthy, except that the heart was rather pale and flabby.

On removing the whole of the diseased mass from the scapula, that bone was observed nearly covered by a cluster of grey, circular tubercles, the whole composed of fine cellular tissue, enveloped in small cysts, and firmly attached to the periosteum, differing only in this respect from those found in the pericardium. (?) The tumours on the sacrum and extremities all exhibited each precisely the same crop of tubercles adhering to the periosteum underneath. All the muscles were blanched, flabby, and softened, and the cellular membrane was infiltrated with a yellow serosity.—*Id.*

A COURT PHYSICIAN.

In an essay written by Sir Henry Hallford, and published a few years ago, we find the following remarkable statement made, regarding the line of conduct to be pursued by physicians, in the matter of publishing accounts of the health of royal personages. The passage, says the Quarterly Review, is "in the highest degree

honourable to the physician who writes and to his illustrious patient."

"If in cases attended with danger in private life, the physician has need of discretion and sound sense to direct his conduct, the difficulty must doubtless be increased when his patient is of so *elevated a station that his safety becomes an object of anxiety to the nation*. In such circumstances, the physician has a duty to perform, not only to the sick personage and his family, but also to the public, who, in their extreme solicitude for his recovery, sometimes desire disclosures which are incompatible with it. Bulletins respecting the health of a sovereign differ widely from the announcements which a physician is called upon to make in humbler life, and which he entrusts to the prudence of surrounding friends. These public documents may become known to the royal sufferer himself. Is the physician, then, whilst endeavouring to relieve the anxiety or satisfy the curiosity of the nation, to endanger the safety of the patient, or, at least, his comfort? Surely not. But whilst it is his object to state as accurately as possible the present circumstances and the comparative condition of the disease, he will consider that conjectures respecting its cause and probable issue are not to be hazarded without extreme caution. He will not write one word which is calculated to mislead; but neither ought he to be called upon to express so much as, if reported to the patient, would destroy all hope, and hasten that catastrophe which it is his duty and their first wish to prevent."

"Meanwhile, the family of the monarch and the government have a claim to fuller information than can, with propriety or even common humanity, be imparted to the public at large. In the case of his late majesty, the king's government and the royal family were apprised, as early as the 27th of April, that his majesty's disease was seated in his heart, and that an effusion of water into the chest was soon to be expected. It was not, however, until the latter end of May—when his majesty became so discouraged by repeated attacks in the embarrassment in his breathing, as to desire me to explain to him the nature of his complaint, and to give him my candid opinion of its probable termination—that the opportunity occurred of acknowledging to his majesty the extent of my fears for his safety. After this, 'when he had set his house in order,' I thought myself at liberty to interpret every new symptom as it arose in

as favourable a light as I could, for his majesty's satisfaction; and we were enabled thereby to rally his spirits in the intervals of his frightful attacks, to maintain his confidence in his medical resources, and to spare him the pain of contemplating approaching death, until a few minutes before his majesty expired."

How court-like is this! A royal personage is to be spared the contemplation of approaching death till a few minutes before dissolution! The nation, also, must not be told the truth, for fear of hurting the comfort of the royal patient. Perhaps this is all right. But it is proper that the public should, at least, know what is the practice in such cases—what is the extent of credit they should give to the bulletins published for their information.

MEDICAL STATISTICS.

STATISTICS OF SUICIDE.

[We find, among the miscellanies of *Wildberg's Jahrbuch d. ges. S. A. für 1837*, several scattered notices on the statistics of suicide. We have collected them, and here present them at one view to our readers]

Paris. The number of suicides in Paris were, for

1830, 269	1832, 369	1834, 436
1831, 377	1833, 333	1835, 477

This is in the ratio of about *one suicide* out of every *one hundred deaths*; while, observes the report, in England, the land of suicide, (!), the proportion is not greater than *one out of every five hundred deaths*.

[Although we think it cannot be denied that the average number of suicides, in relation to the total death, is considerably less in England than in France, we much doubt whether the ratio here given, of 1 in 500, be correct; since so little attention is paid by the government of this country to the collection and publication of the details.]

Naples. During the year 1836, out of a population 357,283 souls, there were not more than thirty-one cases of suicide.

St. Petersburg. The number of suicides in this capital, for the years 1831, 1832, and 1833, did not exceed 104; which presents an average of about thirty-four annually. They were mostly confined to the lower classes of society.

Bohemia. In this kingdom, during the year 1835, the deaths amounted to 119,483. Of these there were 186 cases of suicide, which is in the ratio of about one suicide out of six hundred deaths.

Lower Austria. From the 1st November, 1835, to the end of October, 1836, there were 49,556 death, and out of these 109 cases of suicide. This gives a ratio of about one in 457.—*Wildberg's Jahrbuch d. ges. S. A.* 3 B. 2 h. 1837.

STATISTICS OF STILLBORN CHILDREN.
